LOCAL REPRESENTATIVE WANTED—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to work to receive best wages. No soliciting or traveling. This is an exceptional opportunity for a man in any locality to secure a permanent paying business without capital and become independent for life. Write at once for particulars. Address E. R. Marden, Pres. The National Co-operative Real Estate Company, 1 to 11 Marden Building, Washington, D. C.

WANTED.

MUNN & CO.—Desires to secure the services of a competent patent attorney, skilled in the preparation of patent specifications. Address Munn & Co., Patent Attorneys, 361 Broadway, New York City.

WANTED—Manufacturer to make an article mostly brass, some steel and wood, staple, patented. Steady proposition. On market several years. Communicate with Alden, care of Kasson's, St. Louis, Mo.

WANTED—A man or woman to act as our information reporter. All or spare time. No canvassing necessary. $60 to $200 per month. Nothing to sell. Send stamp for particulars. Salary Association, 834 Association Bldg., Indianapolis, Indiana.

MISCELLANEOUS.

THE LOXOGRAPH TRIANGULAR RULER. Saves time tracing mechanical drawings. Can be moved over a T-rule, ink lines will not smear. Send for circular. The Loxograph Instrument Co., Wilmington, Del.

JUST INVENTED a wonderful device. Agent can be realized after supplying, useful for all liquids. Write for particulars. Address, Mr. Lee, 32 Nassau Street, 361 Street, New York City.

INVENTORS, our experience of ten years developing and building inventions is at your service. Send for booklet. Information free. Thomas-Swain, Mechanical Engineer and Builders, Elwood City, Pa.

MOTORCYCLES CHEAP.—Send to-day for free catalog of new and used motorcycles. Also bargains in sundries and sidestands and/or outfits for converting bicycles into motorcycles. Gear Manufacturing Company, Dept. M, Galesburg, Kans.

GUARANTEED Ratings to 100 horse-power to make $10 money on $1,000 Capital. Our new will yield 100 to 500% in 6 to 12 months. Write for booklet and particulars. Acme Engineering Co., 1000 Acme Bldg., Detroit, Mich.

MAKE BIG MONEY operating a Portable Post Card Machine. Prints, posts, cancels and delivers cards on the spot to the citizens in the open street. No days lost. Experience unnecessary. Write for particulars. Photographic Post Card Co., Dept. 1, 1 Madison Ave., New York City.

FREE—INVENTIONS WANTED. Manufacturers want hundreds of inventions; patented and unpatented; write for list of needed inventions. Patent Selling Co., Dept. 1, 1 Madison Ave., New York City.

FREE—INVENTIONS WANTED. Manufacturers want hundreds of inventions; patented and unpatented; write for list of needed inventions. Patent Selling Co., Dept. 1, 1 Madison Ave., New York City.

FREE—INVENTIONS WANTED. Manufacturers want hundreds of inventions; patented and unpatented; write for list of needed inventions. Patent Selling Co., Dept. 1, 1 Madison Ave., New York City.

Frank Julian Sprague

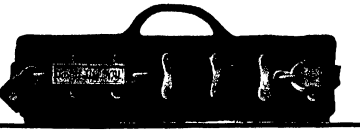
(Concluded from page 365.)

Sprague developed the high-speed screw elevator, the automatic house elevator, the double motor drum elevator and other devices.

While all this was going on Mr. Sprague had offered to run the Manhattan Elevated Railway electrically, but having to deal with progressives of the type of Gould and Sage, he did not get very far. Turning his efforts to Chicago, he there put into service on the South Side Elevated his "multiple unit" system, under forfeiture contract. Once more he made good, with startling results, so that not only in Chicago, for elevated railway work, the multiple unit system is the only one known, but it is the sole dependence of the roads in New York and Boston. Then came the Manhattan Subways, and all the river tube systems—every one an example of multiple unit application.

Mr. Sprague's fundamental and basic patent on this contains nearly 300 claims, a good multiple unit in itself, and a fair exhibition of reticence on the part of a man who would rather talk and fight and invent any time than listen to music and the drama—though he dotes on both.

Of course such an inventor and engineer was early drawn into the work of changing over for electricity the big terminals of the trunk railroads, and hence he is found on the consulting staff of the New York Central. He was also retained by Harriman as to similar work on the Southern Pacific. In these developments he has been understood to stand strongly for the use of the direct current, against the alternating, as used on the New Haven road, but at the same time he has advocated hitting up the potential for direct current work, and has jumped it from 600 to 1,200 volts, with very satisfactory results. He has also been a stout advocate of the protection of the third rail, with devices exemplified on the New York Central and several other roads. More lately, Mr. Sprague has returned to the subway problem, by tongue and pen has advocated reforms and improvements, and has even offered to undertake, with full financial responsibility, the construction needed to relieve the frightful congestion on the older lines.



There is not much of Sprague to look at, but it is all fighting weight, nerve, grit, go, snap and confidence. He has crossed the 50 line, but does not suspect it; and the dark hair, flashing eye, equiline nose, sharply-cut chin, alertness of movement, tenseness of poise, all tell of a very live human being. He has an acutely mathematical mind, tempered, fortunately, by humor and imagination, but he is concentrated, and no matter what you may want to talk about, has no difficulty whatever in swinging the conversation back to the thing he is interested in. A more loyal and generous friend could not be imagined, but there are some persons he will omit from his will. To this day he maintains the keenest interest in the profession of his early years, and his appointment as visitor to the Naval Academy is still regarded by many conservatives as perhaps the saving feature of the Roosevelt administration.

Relative Strength of Italian and Turkish Navies

(Concluded from page 371.)

Of less important cruisers of the protected type Italy possesses ten, of from 2,250 to 3,500 tons, and from 17 to 20 knots speed. Their armament consists generally of from four to six 4·7-inch or 6-inch rapid fire guns. The navy includes two 23-knot torpedo cruisers and eight gunboats, the latter fitted for laying mines. The torpedo fleet is made up of twenty-three destroyers, of 28 to 30 knots speed and about 350 tons displacement. Also twelve destroyers of 620 tons and 30 knot speed are under construction. The torpedo fleet also includes eighty-one completed torpedo boats and thirty under construction. In the submarine flotilla are the "Delfino," 107 tons, 6 and 9 knots, the five "Glaucos," 160 tons, 9 and 14 knots, the "Foca," 280 tons, 9 and 15 knots, and eleven vessels under construction or about to be commenced.

At the present writing no engagements of any importance appear to have taken

POSTAL LIFE BUILDING

25 Nassau St., New York

The Postal Life Insurance Company pays *YOU* the Commissions that other Companies pay their *agents*

45% of the first year's premium is the average *Commission-Dividend* being paid to each POSTAL policyholder on entrance into the company. Other companies would pay this sum to an *agent*—as *his* commission.

That's for the *first year*. In *subsequent* years POSTAL policyholders receive the *Renewal Commissions* other companies pay their agents, namely, 7½%, and they also receive an *Office-Expense Saving* of 2%, making up the

Annual Dividend of 9½% Guaranteed in the Policy

And the POSTAL pays the usual contingent dividends *besides*—ranging up to 20% of the annual premium.

Such is the POSTAL way, it is open to *you*. Call at the Company's offices or *write now* and find out the exact sum it will pay *you* at *your* age—the *first* year and *every other*.

Abbott-Detroit "44"

A Standard American Car with the Best of Europe Added

A symphony of mechanical excellence and refinement—that's the Abbott-Detroit "44", the sumptuous seven-passenger, fore-door, torpedo car built for permanence and guaranteed for life by the Abbott Motor Company, Detroit.

The cardinal features here enumerated and which are frequently embodied in cars of the $4,000 type are seldom incorporated in cars selling at Abbott-Detroit prices. Exceptionally large and roomy body, hand buffed leather upholstery, with thick cushions, black walnut natural finish—dash and trimmings, highest class finish—24 painting operations; springs, oil tempered, three-quarter elliptic springs in rear, giving exceptionally easy riding qualities, full floating type rear axle, chrome nickel steel drive shaft; multiple disc clutch, three-bearing crank shaft, unusually large valve openings; Timken roller and imported Schaefer annular bearings throughout; extra large tires, reducing tire expense; gear shifting device noiseless, easily handled; large, strong, artillery wheels, latest type of fore-door body with inside control.

***This car* IS THE SERVANT—*not the* MASTER OF ITS OWNER**

It is the policy of the Abbott Motor Company at all times and at whatever cost to keep its product representative of that which is best and most up-to-date in American and European automobile construction. We constantly work for the improvement in design and materials, and add the improvement the moment its particular reliability has been demonstrated, and at the same time proved to be a valuable adjunct of the car. The rigorous application of this policy keeps the Abbott-Detroit line of models always timely and new. The customer does not have to wait for a new season in order to see predominating features of standard construction—refer to the Abbott-Detroit at any time—the standard car that's always up-to-date.

Young Man! Here is the King of Professions. Our complete, practical and easy HOME INSTRUCTION CORRESPONDENCE COURSE, studied during spare time, will make you an expert—if you have the desire and the will. Why be tied down to menial work, a small pay, when you can be a trained man at a big salary? Our school is one of the largest and best-known home instruction institutions in the world—teaching Architecture, Business and Engineering. TUITION PAYMENTS ARRANGED. ENDORSED BY MR. FRANK E. VAN DERLIP. Write today for illustrated booklet "FROM PENCIL TO PLAZA-TOP"—It tells you how to make BIG MONEY.

AMERICAN SCHOOL OF CORRESPONDENCE Dept. 220 Chicago, Ill.

place between the two navies, and it is not likely even in the event of a protracted war, that the struggle will shed much light upon the leading naval problems of construction, tactics and strategy

Small Isolated Electric Power Plants

(Concluded from page 874.)

main battery Each cell may consist simply of two plates of sheet lead suspended in a jar of electrolyte.

At *W* is indicated a variable resistance which must be used during the process of forming the home-made battery previously described This will need to have a resistance of about seven ohms and a current-carrying capacity of six amperes

When the switch, *S*, is closed to the left it connects the battery directly to the load through the upper blade The lower switch point is not used for anything on this side, but its clip makes a most convenient place to keep a spare eight-ampere fuse When it is desired to charge the battery the dynamo is started, and, by manipulation of the field regulator, *R*, is brought up to a voltage sufficient to light the lamp, 1, to about half its candle power The switch is then thrown to the right, connecting the battery to the dynamo through the upper blade, and both battery and dynamo together to the load through the lower blade and the three c e m f cells The charging of the battery may be done during the day or at night, as may be most convenient

When fully charged, a 36 ampere-hour battery will run seven 16 candle-power lamps for eight hours, and it will require a current of five amperes for eight hours for the recharge Assuming an average evening's use of four lamps for 3½ hours it should suffice to charge the battery twice a week In winter, when the evenings are long, it may need to be charged every other day On occasions of unusual demand, such as parties or receptions, to prevent the battery being exhausted too rapidly, it is necessary for the dynamo to be run in the evening to carry a part of the load The same thing is true in cases where it is desired to use an electric flat-iron or vacuum cleaner, which easily can be done by keeping the dynamo going all day on "ironing day" and "cleaning day"

The foregoing specifications, as stated in the beginning, apply to a small sized installation where lighting is the principal requirement Before installing a 32 volt plant, careful consideration should be given to the subject of future extensions Electric cooking and other heating appliances, motors and the like not only require a larger plant to run them, but it is desirable to operate them at a higher voltage in order to keep down the size of the copper conductors necessary to carry the large currents imposed by low voltage For larger plants sixty volts has been adopted as a standard, and makers of lamps, heating appliances, etc., now carry these in stock made for this voltage The following specifications will give a good idea of what is needed for a 60 volt plant

Battery, 30 cells two-plate type 36 ampere-hours capacity and 6 c e. m f cells, or 60 cells of the home-made battery, connected thirty in series and two in multiple, with 6 c e m f cells all in series

Generator, shunt wound dynamo 77 volts, 5 amperes, speed about 2,000 r. p m

Engine, one horse-power

Ammeter, 10-0-10 scale; voltmeter, 80 volt scale

This outfit will have twice the capacity of the one previously described. It would be suitable for a connected load of forty 16 c p lamps where the maximum demand is limited to twenty-five. The battery alone will be large enough to handle light intermittent loads through the day, such as coffee-percolator electric toaster, or a one-half horse-power pump motor for the house tank supply This outfit is adapted for future enlargement by the addition of more battery, but if this is anticipated in the very beginning it would be better to install a larger charging equipment—say a 3 horse-power engine with a 77 volt 10 ampere dynamo, and to have the ammeter scale marked 30-0-20.

The Electrical Show in the New Grand Central Palace

THE New York Electrical Show, this year, was used to open the new Grand Central Palace, located on Lexington Avenue, between 46th and 47th streets. This handsome structure was brilliant with myriads of electric lights, which were reflected with great brilliancy by the white walls of the interior At the top of the building on the outside the arched gallery was illuminated with mercury vapor lamps, the bluish light of which gave a soft, delicate effect when viewed from a distance in the light of the full hunter's moon

Several of the large electric companies have excellent exhibits of all kinds of household electrical apparatus Along the south side of the building there is a row of rooms illustrating the equipment of a modern house from kitchen to bedroom In the former room there is an electrical washer, a churn, a chopping machine, and a full equipment of cooking utensils, while in the bedroom there is an electric massage instrument, a miniature hair-drying fan, an electrical-operated sewing machine, etc The company also has a complete electrically operated printing plant along the west side of the building A small paper is printed every day, giving the latest news, many of the despatches being received by wireless.

A particularly interesting display was the historical exhibit in the gallery This consisted of old books dating back to the time of Franklin, and various electrical apparatus The most interesting feature, perhaps, of this exhibit was the development of the arc lamps, from the original Brush twin-carbon lamp, to the flaming arc lamp of the present day

Storage batteries and electric automobiles occupy a considerable part of the floor space, there being exhibits by the Edison Exide, and Gould storage battery firms, as well as electric automobiles of most of the leading makes The recent record of 110·9 miles made on the Ocean Boulevard between Brooklyn and Coney Island by a Fritchle electric car, carrying four people, which was made with a lead battery, has been exceeded under actual touring conditions by the Edison battery, which, about a year ago, received a thorough testing under Edison's supervision, in pleasure vehicles Some time after, a run of 244½ miles at the rate of 12 miles an hour, was made with a Baker electric auto on city streets in Cleveland, with a 40-cell 225-ampere-hour Edison battery This is the record for tests of the kind just mentioned, while *for touring purposes*, from 125 to 150 miles, it is claimed, can be made on one charge Plates taken from a cell which has been in continuous use in delivery service in New York city for two and one-third years, and which has run a delivery wagon 25,000 miles, were exhibited and showed no depreciation. The capacity of these cells is said to have risen from 225 to 300 ampere hours after this long-continued use In addition to this increase of capacity with use, the Edison battery has the advantage that it can be charged whenever convenient, and is not ruined if left standing in a discharged condition. The Electric Storage Battery Company also exhibited vehicles and stationary cells.

A barber shop equipped with all the latest electrical appliances, was located in the middle of the main floor, while on a raised platform above there was exhibited a novel combined electric piano and violin orchestra Three violins were mounted upside down in a circle above the piano, and were played by means of a revolving ring, rotated at various speeds in producing different notes. Whenever a note was struck on a violin, the instrument was moved about its neck as a pivot until the strings contacted with the ring Meanwhile, electrically-operated levers fingered the strings The music produced by this orchestra was excellent nd the amount of expression secured was surprising.

As a whole, the show this year is made up of small apparatus There are none of the big motors and generating sets that have sometimes been exhibited when the show was held in Madison Square

THE BEST LIGHT

Makes and burns its own gas. Puts to shame all candle power lights, more brilliant than electricity or acetylene. Cheaper than kerosene. Costs no smoke. Costs two cents per week per lamp. No dirt, no grease, no odor. Used in every civilized country on earth. Over 200 styles. Every lamp warranted. Agents wanted. Write for catalog.

The Glidden Tour and the Fairmount Park Automobile Race

MORE than fourscore automobiles started in the 1911 Glidden tour from New York city on October 14th The route this year extends 1,456 miles from New York to Jacksonville, Florida The trophy will be contested for by teams, the team having the best average of prompt arrivals being the winner There are various divisions for runabouts and touring cars, besides which there are several three-wheeled motorettes and a number of trucks and baggage cars It is expected that the 1911 tour will be the most successful of any held thus far, as the roads of the South have been greatly improved during the last few years, which should assure the motorists an enjoyable trip

On October 9th, there was held in Fairmount Park, Philadelphia, the automobile race for fast cars, that has been run annually for the past several years This race was notable for the fact that there were no accidents of any sort, and yet the speed records were broken, principally by amateur drivers. The winner of the race was Erwin Bergdoll, in a 90-horse-power Benz His time was 3.18 41.35—an average of 61.25 miles an hour He beat by 10 minutes 26.53 seconds the time of Zengel, in a Chadwick car last year In fact, no less than six of the nine cars that finished this 202½ mile race, beat the time of the winner last year, which was 3 39 07.88 Spencer Wishhart, in a Mercedes, secured second place in 3.20.11.42 He held the lead for three laps, but was finally outdistanced. Ralph Mulford, in a Lozier, obtained third place His time was 3.21.52.78 He stood a good chance of coming in second, but was obliged to stop for gasoline and oil near the end of the race, and in so doing lost his position Last year Mulford finished but six seconds behind the winner.

Mr Bergdoll beat the best record for one lap no less than six times, besides equaling it once during the race The time of 7.36 for the 83-mile lap, made by Harround in a Marmon car last year, was reduced to 7 minutes and 28 seconds by this amateur racing driver. Several other well-known automobile racing men finished in the remaining places Zengel, in a National, was fourth, and Disbrow, also in a National, was fifth, while Harry F Grant, twice the winner of the Vanderbilt cup race, was sixth A small car the Mercer, obtained seventh place in 3.29 45⅗ This race was particularly interesting from the fact that the first and second places were won by amateurs The next big race of this kind will be held at Santa Monica, Cal., shortly

Repairing Old Bridges by Injecting Cement

AT Hamburg there are two bridges the masonry of which was threatening to fall in ruins, being traversed by innumerable cracks of varying size A rather remarkable process has just been made use of to rejuvenate these bridges. A number of holes were bored throughout the structure so as to give access to the interior, and cement was injected by pumps under pressure Reports on the present condition of the two bridges thus treated are entirely favorable.—*La Nature.*

Comparison of the Distance Traveled by Earth and Bell Telephone Messages

The Orbit of Universal Service

In one year the earth on its orbit around the sun travels 584,000,000 miles; in the same time telephone messages travel 23,600,000,000 miles over the pathways provided by the Bell system. That means that the 7,175,000,000 Bell conversations cover a distance forty times that traveled by the earth.

When it is considered that each telephone connection includes replies as well as messages, the mileage of talk becomes even greater.

These aggregate distances, which exceed in their total the limits of the Solar system, are actually confined within the boundaries of the United States. They show the progress that has been made towards universal service and the intensive intercommunication between 90,000,000 people

No such mileage of talk could be possible in such a limited area were it not that each telephone is the center of one universal system.

Its Great Advantages are 1st—Lowest Fuel Cost, pays for itself in Fuel Saving. 2nd—Delivers Steadiest Power Stream, adapting it especially for operating farm machinery. 3rd—Easy on the machine it operates. 4th—Uses Gasoline, Kerosene or Gas. 5th—Perfect Lubrication. 6th—Starts Easily and Quickly, occupying minimum space. 7th—It is the King of Portable Engines. No engine has so wide a range of use. You will make a mistake if you do not write for information. We make 1½ to 6½ H. P. single cylinder engines, 6 to 20 H. P. two cylinder engines, 30 to 90 H. P. four cylinder engines. All heavy duty, slow speed engines For survey of operation and low fuel cost our engines haul Temple Pump Co., Manufacturers, 439 West 15th St., Chicago, U. S. A. This is our 50th year.

INVENTORS' NUMBER

NOVEMBER MAGAZINE NUMBER of the SCIENTIFIC AMERICAN

ISSUE OF NOVEMBER 18th, 1911

Although every number of the Scientific American discusses the inventions and inventors of the day, there will be published on November 18th a mid-month magazine number which will display the inventor in a new light. Articles will be published which will show how much he suffers from our antiquated legal system and will explain his need of sympathetic governmental support. His foibles, too, will not escape notice.

There will be an arraignment by Mr. Melville Church of our marvelously complicated method of trying patent infringement suits. Mr. Church is one of the most eminent patent lawyers in this country, a man who has figured prominently in some of the most important patent cases that have been tried in this country. He points out what a burden is imposed by the present method of taking testimony in chambers without any Court supervision and how enormously expensive a trial may be before the infringer is successfully brought to book. We need only mention the scores of volumes of printed testimony taken during the trial involving the validity of the Selden patents, to drive home the utter absurdity of our Court procedure. The inventor who has suffered because of the slowness of our judicial machinery will read Mr. Church's article with interest and profit, for he will learn what steps are being taken to protect without impoverishing him.

The great industrial corporation (the "Trust" of whom we have been hearing so much of late) has changed the aspect of invention. It now pays to invent thousands of little feeding devices, thousands of little trains of gears and levers and cams, which, fifty years ago, might not have proved so profitable. An invention that means a saving of one cent per ton in the handling of raw material becomes of industrial importance for the simple reason that the "Trust" deals in gigantic masses. In an article entitled "The Industrial Corporation and the Inventor" this aspect of modern invention is treated.

Fascinating is the story of making big fortunes out of patents on small and apparently unimportant things. Every time anybody in the United States pulls the cap off a beer bottle or a soda water bottle, he puts the fraction of a cent into the pockets of a Baltimore inventor. Elias Howe, who first made the sewing machine practical by placing the eye of the needle near the point, admitted that he had collected $1,185,000 in royalties. The man who invented ingrain carpet with the threads so interwoven as to prevent wrinkling, is now better off by $4,000,000 for his thought. A government clerk named McGill found it hard to hold together many pages of thick documents. He got over the difficulty by inventing the little brass paper fasteners which we all use. He died rich. His invention made money. These are but a few of the facts taken from a striking article by Mr. William Atherton DuPuy on the big fortunes that have been made on little inventions.

Perpetual motion is the inventor's Will-o'-the-Wisp. In the Inventors' number will be found an article in which the various forms of perpetual motion apparatus that have engaged the attention of dreamers for years are explained and their fallacies set forth.

There is a funny side to invention as the Inventors' Number will tell you. What possible use could there be in encouraging birds to infest the farmer's grain fields by providing fence posts with birds' nests in them? Or of table knives with mirrors in the handles to permit the users to inspect their teeth now and then? Or of a telescopic anti-collision pilot for railway trains running in advance of the locomotive and bearing an automaton that rings a loud gong? These and even more ridiculous inventions will be described in the article on "The Funny Side of Invention."

In addition to these articles, there will be the usual Scientific American material—the articles on current scientific discoveries, the Department of Curiosities of Science, the Science Abstracts and the rest.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The Spirit of the Coliseum

A CERTAIN number among the multitudes that poured into the Coliseum in the days of ancient Rome were drawn thither solely by the true sporting instinct, which delights in witnessing feats of skill and endurance. The large majority went to witness the spilling of blood, for even the noble Roman matrons, we are told, in response to the inquiring glance of the victorious gladiator, would turn their thumbs down, indicating that they wished to see the life blood of the vanquished redden the sands of the arena.

Can it be possible that a touch of the savage desire to look upon mangled bodies and hear the sob of expiring life, which slumbered beneath the superficial civilization of the Roman people, is responsible for the vast crowds which gather at our modern race tracks to witness the criminally dangerous automobile race, or watch the aviator straining for a fall with Death, a thousand feet in midair?

There was a time when the automobile race, run over the highways of the country, possessed a distinct scientific and technical value. The supreme test of the strength and endurance of materials which was afforded by those contests, was one of the most valuable factors in bringing the automobile to its present perfection, and the brave fellows who lost their lives may be considered as having been sacrificed in a just cause, since they rendered possible the rapid advancement of a new means of transportation—possibly the most valuable that was ever introduced.

To-day, however, any legitimate reason for the holding of automobile races, particularly on dangerous race tracks, has disappeared. That such races, in spite of their frequent and frightful fatalities, continue to be held is to be explained by the co-operation of what Mr. Roosevelt has recently denominated as "commercialism and hysteria." If the possibilities of sudden death or horrible wounding were eliminated from these exhibitions, we venture to say that the promoters who, to us, on this morbid taste on the part of the public would quickly find that such exhibitions were altogether unprofitable. The element of novelty has long ago passed from such contests. Every one knows that if 200 horse-power is crammed into a racing automobile the machine will skid around an ordinary race track at a speed of something under 50 seconds to the mile, and every one knows also that a crowd of twenty to thirty high-powered racing machines will average on a specially-prepared track over seventy miles an hour. Should the time ever come when tires no longer burst, nor steering gears give way, nor roaring monsters go hurtling through a crowded mass of humanity at the rail, we venture to say that automobile racing is a sport will be as dead as croquet or shuttlecock and battledore.

The same argument holds as regards many of the so-called aviation meets. Continuous flying around a circular or oval course is monotonous. The public demands the spectacular in the form of "dives," "spirals," and other aerial gymnastics that are performed at imminent peril to life and limb. How often during the past year has the unfortunate aviator launched himself into the air under atmospheric conditions which he knew to be more than perilous—being driven to it by the jeers of a crowded grand stand and the importunities or threats of a professional promoter or the "local committee" of a bill-placarded and expectant city. The death of an aviator under such conditions comes very near to being homicide of the most atrocious character.

Let it be understood that the SCIENTIFIC AMERICAN is now speaking of so-called "aeroplane meets" which are exploited purely for commercial gain. Such gatherings as were held last year at Belmont Park, in which the pick of the aviators of the world contested, and where everything that could be done was done to satisfy the public and at the same time safeguard the contesting aviators, fulfill a useful purpose. They encourage the art as the automobile contests of eight to ten years ago served to develop the automobile and build up a great industry. Of even greater value are well-organized cross-country races. We venture to say that the art of aviation receives more stimulus from such a flight as that of Atwood from St. Louis to New York, or the present remarkable and so far successful attempt of Rodgers to fly from the Atlantic to the Pacific, than it does from a whole season of the present irresponsible aeroplane exhibitions, with their shocking list of fatalities.

The Scrap Heap

ONE of the most marked distinctions between American and European practice in the technical arts is the free use (amounting in foreign eyes to positive extravagance) which we make of the scrap heap. Possibly the difference is due to the much greater cost of labor in this country; but whatever the cause, the fact remains that whereas in Europe there is a tendency to repair, rebuild or even largely re-design existing machinery, in the effort to keep it upon its legs as long as possible, here in America it frequently happens that a comparatively recent installation of costly machinery will be torn out and sent to the junk pile, to make way for an entirely new plant embodying the latest improvements.

We do not have to go far to find cases in point. Many of us will recollect the pride with which it was stated in the English press a few years ago that such and such a locomotive had recently left the railroad shops, after a thorough overhaul, and was again in service, with a record of Heaven knows how many decades of continuous service behind it, during which it had covered some millions of miles of track. Now to American eyes, although such a fact speaks volumes for the well-known excellence of British workmanship, the mere existence of a forty or fifty-year-old engine in service indicates that conservatism is being carried too far, and that English railroad methods lack that flexibility which is necessary for the best results. Perhaps the value of the scrap heap has never been shown to better effect than among American railroads and in those vast industrial plants and organizations which are covered by the steel trade. Where one enormous locomotive can be made to do the work of two, our railroad men never hesitate to discard the smaller in favor of the bigger unit, and instances have not been wanting where, in the manufacture of steel, a vast and costly plant has been "scrapped" to make way for some improved machinery, which, by virtue of its reduction of labor costs and general speeding up of the process, gave sure promise of not only paying for the discarded plant but producing the manufactured product at a lower cost.

It is agreeably to this policy that certain older ships of our navy are put up for auction, or towed into shallow water, as was the old "Texas," to serve as targets for rifle practice. We regret to note that not a few people have criticised the destruction of the "Texas" as a piece of wanton extravagance. As a matter of fact, this obsolete vessel is giving far more value to the navy as a target than she ever did during the palmiest days of her commission. The battleship or cruiser which has been "outbuilt" by the rapid march of improvement in naval material is more profitable as old junk than as lying in reserve at a navy yard. The money spent upon these ships in the endeavor to modernize them might just as well be poured into the sea. One dollar put into absolutely new construction is worth a million spent in tinkering up obsolete ships.

As with the ships, so with the navy yards. The last report of the Secretary of the Navy tells us that we have several old yards which have outlived their usefulness and constitute a charge upon the country for which it gets practically no return. The policy of the scrap heap should be applied here with an unsparing hand.

New Orleans yard, to which no large ship of our navy could be sent in war time, for fear of its being blocked in at the passes; Port Royal and Charleston, both absolutely useless for battleships because their channels are silted up with sand and mud; New London, barred from the sea by a railroad bridge—these and others should be scrapped and abandoned. The maintenance of these lesser and useless yards from motives of sentiment or politics is working decided harm to the interests of the navy at large by the diversion of money, time and attention from those fundamental objects at which the present enlightened policy is aimed.

The Status of Agricultural Meteorology

THE French Chamber of Deputies, at its session of December 22nd, 1910, passed a resolution calling upon the Ministry of Agriculture to undertake the development of work in agricultural meteorology—already carried on to a limited extent by the Department of Agricultural Hydraulics—and to take steps with a view to providing in the budget of 1912 for the organization of a special service devoted to this subject. By an order of April 10th, 1911, a committee of sixty-four members, having at its head M. Violle, of the Institut de France, was organized under the direction of the Ministry of Agriculture to prepare plans for the proposed service. At the same time the French government sought the advice of organizations in other countries engaged in this class of work, including the United States Department of Agriculture. Apparently the new service is to be independent of the existing meteorological department of the French government, viz., the Bureau Central Meteorologique, which is under the Ministry of Public Instruction.

It is noteworthy that France, following the example set a few years ago by Russia, is about to organize a separate and distinct meteorological service for the benefit of agriculture. In the United States, official meteorology is already under the direction of the Agricultural Department, to which the Weather Bureau is attached, and the act of Congress under which this bureau was organized provided that it should be "specially developed and extended in the interests of agriculture", but in foreign countries an analogous affiliation does not generally exist. Apparently the European meteorological services, which for the most part have but meager funds at their disposal, are not able to be of much direct benefit to the tillers of the soil; and as a distinct group of problems, theoretical and practical, is involved in agricultural meteorology, it has seemed best to organize special services, rather than extend the scope and enlarge the resources of the general services already existing.

This movement found expression at the last meeting of the International Institute of Agriculture, at Rome, when the French delegate, M. Louis Dop, presented an elaborate report on the work in agricultural meteorology now officially carried on in various countries, and offered a resolution, which was adopted, looking to the international organization of such work. This matter will be submitted to the International Meteorological Committee, which, it is expected, will appoint a "commission" on agricultural meteorology, co-ordinate with the commissions that have been appointed from time to time on aerology, atmospheric electricity, solar radiation, etc.

The subject of agricultural meteorology, owing to the fact that it has not heretofore been looked upon as a distinct branch of science, has received far less attention than its immense economic importance entitles it to. The interrelations of weather and climate, on the one hand, and the life and growth of plants on the other—including such matters as the geographical distribution of plants, photochemical climate, phenology, the causes and effects of frost, the meteorology of soils, æolian geology, acclimatization, drought resistance, and such practical problems as frost protection, hail insurance, and weather forecasting for particular crops—should be recognized as a field of research requiring the attention of a numerous corps of workers, trained in both meteorology and biology. At present the workers in this field are very few. Particular problems have been studied from the meteorological or from the biological point of view, but no general survey of the field has yet been taken, and there does not exist, to this day, a textbook of agricultural meteorology worthy of the name. There is no greater desideratum, in the literature of either meteorology or agriculture.

A New System of Gathering Turpentine

Conserving the Long-leaf Pine

THE old system of boring long-leaf pine trees for the purpose of collecting turpentine is the most wasteful and destructive method that has ever been used. It is not only the most expensive from the standpoint of labor, but it invariably weakens the trees and always subjects them to destruction from wind and fire. Less wasteful methods have been devised for extracting the resin, yet a good many turpentine men persist in cutting large receptacles or openings on either side of the trees near their bases in which the resin collects. (See Fig. 1.) These holes or boxes, as they are commonly called, are from 8 to 14 inches wide, running up 7 to 8 inches along the length of the tree, and from 4 to 6 inches deep. The trunks are repeatedly hacked immediately above these boxes, thus exposing new scarified surfaces from which the resin oozes and collects in the boxes below. This process of hacking is continued upward on the trunks as high as the men can conveniently reach, and is repeated for five to seven years until the trees are considered fully worked.

With this method there is an enormous amount of waste. Not only is there a 50 per cent waste through evaporation of the pure turpentine oil, which sells for $4.00 per gallon, but in gathering the crude resin from the boxes large quantities are lost through careless handling. A good deal of foreign material, such as scales of bark, chips and needles of the trees, becomes mixed with the crude resin which is collected from the boxes and scraped off the scarified surfaces.

About ten years ago another method was devised which is known as the cup and gutter system. This system has its advantages over the old one in that it does away with the injurious methods of cutting the boxes into the trees. Only the sap wood of the tree is penetrated by this method, and one cup with two gutters which drain the resin into the cup is attached to the foot of each scarified surface. (See Fig. 2.) These cups have a disadvantage in so far that hogs and other animals which feed in the pine forests frequently throw them off the hooks which hold them in place. Evaporation is not wholly eliminated by the use of this method. The earthenware cups also have another disadvantage, since a good many are constantly broken even under reasonably careful handling and must be replaced at a considerable expense. Nor does the use of this system greatly lessen the fire danger, for the resinous substance on the scarified surfaces often catches fire when the woods are burned over, which is done regularly every year in the southern pineries. These periodic conflagrations which consume annually not only millions of acres of young growth but also many millions of feet of merchantable timber, can thus be directly or indirectly attributed to the cause of improper methods of turpentining. The present rate of this destruction is so great that within the next fifteen or twenty years the resin yielding pine forests of the South will be wholly depleted.

It is very important, therefore, that a less destructive method of turpentining should be used. A new system of collecting turpentine in air tight jars which was put into practice a little less than a year ago promises to be the most economical method ever devised, and it is this system which may possibly revolutionize the turpentine industry in this country. To

Fig. 1.—The old "box" system.

Fig. 2.—Cup and gutter method.

Fig. 3.—System of turpentining with an air-tight cup attachment.

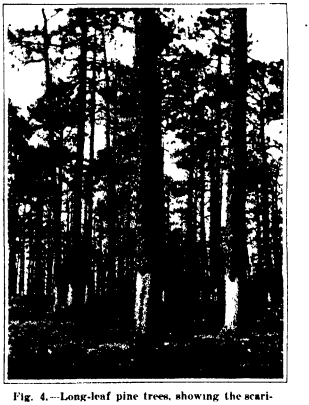

Fig. 4.—Long-leaf pine trees, showing the scarified surfaces.

A NEW SYSTEM OF GATHERING TURPENTINE

cut the timber without having it turpentined is equivalent to throwing away the whole of the profits that could be derived therefrom. But the turpentining should be done only provided the oil can be extracted, with absolutely no damage to the timber or to the lumber product. Frequently turpentine men lease their long-leaf timber for $2.50 per acre for the privilege of working it for the turpentine, though the timber on it may be worth $4.00 per acre to the saw mill men. After the turpentine operator is through with the job fully one-half of the trees are invariably dead, all are fire scarred, and those which remain after nine years (the usual length of a lease) are worth to the millmen only about $2.00 per acre.

The new turpentine cup system consists of an air-tight glass jar of about one pint capacity which screws into a metallic cover similar to a tin can top. (See Fig. 3.) To this is attached a somewhat similar cap at right angles which is placed into a shallow 2 inch hole bored into the sapwood of the tree. A metal brace of the same material as the cover serves to hold the caps at right angles to each other. The brace is hollow and provides a passage for the resin from the tree into the glass jar which is attached to the horizontal cap. The cup is firmly attached to the tree by first smoothing off the rough outer bark over a few square inches and then placing an ordinary extension bit of the vertical cap into the hole to a depth of about one-fourth inch. Before forcing the vertical cap into the hole two three-quarter inch diverging holes several inches deep with a slightly upward inclination are bored from the center of the larger hole. The vertical cap is then bored into the large hole and a glass jar screwed into the horizontal cap. The gum flows from the three-quarter inch holes into the vertical cap and from there through the hollow brace into the glass jar. When the jars become full they can be unscrewed emptied and replaced.

This method has proved very successful, and it will not only be a great thing for the turpentine industry but it will be a great step in advance toward conserving the long-leaf pine which is being rapidly depleted through improper systems of extracting the turpentine. The system has the advantage that it can be continued for an indefinite period without damage to the tree. It is the only method that protects the trees and saves all waste. The pines thus tapped will last for a number of years. The system not only does away with the old chopping or hacking method which is very expensive and destructive operation but it protects the tree from fire which is almost inevitable when dry scarified surfaces are exposed and moreover the trees are not retarded in their growth.

Wooden Shoes

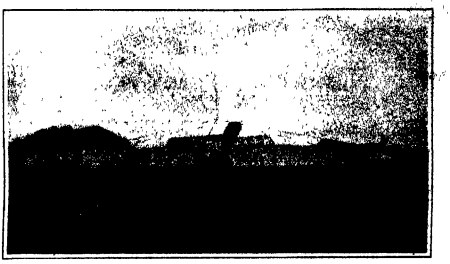
ACCORDING to a report from Vice Consul D. P. De Young at Amsterdam, Holland exports more wooden shoes to the United States than to any other country. Many hundred pairs are now worn in Michigan, Iowa, Missouri, New Jersey, and other States. The remarkable statement is made that there is more wooden footgear worn in Chicago, Grand Rapids, or Holland, Mich., than in the city of Amsterdam. Other sections importing this practical article of dress extensively are Paterson, N. J., St. Louis, Mo., Lancaster County, Neb., and Marion County, Iowa.

The shoes exported from the Netherlands are mostly made in large factories by modern machinery. On the contrary, the wooden shoes worn in that country are generally hewn to the measure of the customers' feet in the village shoe shops, and the local price varies according to the amount of lumber used and the market price of the raw material.

Two New Blériot Monoplanes

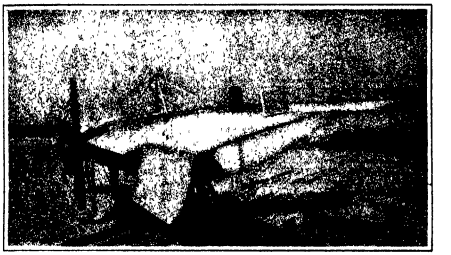
Descriptions of the Latest Aeroplanes of the Celebrated French Pioneer

Not content with having won practically all the great European circuit aerodrome races during the past summer, M. Blériot has been hard at work of late evolving new designs. His two latest monoplanes, one a racer and the other an experimental "Canard" or "Duck," are illustrated herewith.



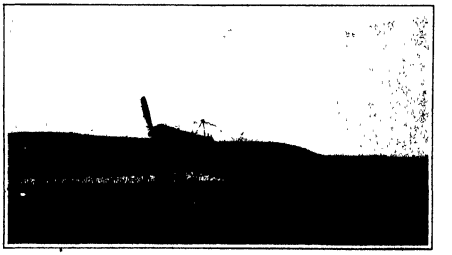
The new racer displays a general refinement of lines and an effort to reduce head resistance. To effect the latter, the upper flat cross member of the chassis has been lowered and placed under, instead of on top of the body. The resulting shortening of the steel-tube uprights of the chassis serves to reduce head resistance. But in addition to this the body has been made extremely narrow in front, while at the rear it flattens completely and terminates with an absolutely flat horizontal rudder. The extreme front end narrows down to not much over a foot in width but where the aviator sits it is of comfortable space. The motor and tanks are well covered with a long aluminium hood so that there is little chance for the aviator to get oil in his face from the exhaust of the motor or from leaking tanks. The usual running gear and shock absorbers are used in front while the bamboo skid is now placed at the extreme rear end of the body or fuselage. Besides a simple V-shaped support for the guys above the wings, this new racer has the same arrangement below, but the tubes which form the lower support are considerably longer than heretofore and they are well guyed to the body. They carry at their lower ends the warping mechanism, which seems to be somewhat different from that used heretofore. The vertical rudder is of peculiar shape, its location on top of the body being similar to that of the rudder on the No. XII.

This new model No. 27, has a length of 7 meters (23 feet), a spread of 8.9 meters (29 feet) and a supporting surface of but 12 square meters (129 square feet). The weight complete is 430 kilograms (948 pounds), so that the weight lifted per square foot amounts to some seven pounds. With a 50 horse-power Gnome motor, this model Blériot has developed a speed of 130 kilometers (81 miles) an hour.



One of M. Blériot's early monoplanes was constructed upon the same lines as his latest "Canard," as this type of aeroplane with pilot in front in a covered body and motor behind has come to be called. The Voisin brothers were the first to bring out a biplane of this type some months ago, although Santos-Dumont was the inventor of it and the first aviator in Europe which he became with this type of machine. The Voisin "Canard" has a much longer body. It has been fitted with hydroplane floats and has made many excellent flights from the water. It is seen skimming the surface in one of our illustrations.

The new Blériot "Canard" is much shorter than the Voisin. It is a monoplane with a thick short body projecting out in front, the horizontal rudder being at the bow. Two vertical rudders on top of the main plane at each end serve to steer. The wings are guyed to an inclined rod underneath which extends forward from a shoe on the bottom of a vertical post. There is no warping, generous ailerons being used instead. The leaf spring, axle and the stout to which the wings are guyed, recall the Nieuport monoplane. They are quite similar.



The total over-all length of this new monoplane is but 6.5 meters (18 feet). The spread and surface are the same as with the racer, while the weight with a 50 horse-power Gnome motor is 400 kilograms (882 pounds). The aviator's seat is so far forward that it would seem as though he ran very little chance of being injured by the motor in case of a smash, since there are five or six feet of stout fuselage between the engine and the pilot. No flights of any moment have been made so far as we know by this new machine as yet. There is no doubt that it will fly, however, nor that a machine of this type offers several advantages, such as have already been mentioned by Voisin in the description of his "Canard" in the SCIENTIFIC AMERICAN of recent date.

Rear view of the Blériot Canard.

The Blériot Canard, with motor and propeller at the back of the aviator.

The new Blériot No. 27 as seen from the rear.

TWO NEW BLÉRIOT MONOPLANES

The Aeroplane in Naval Service

By André Beaumont

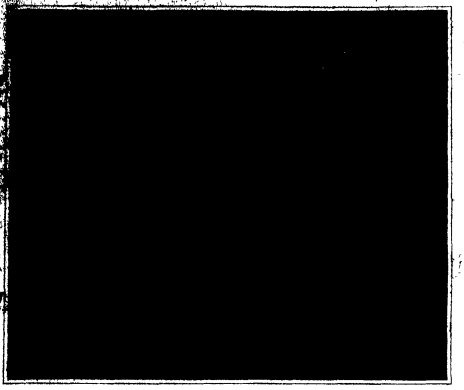
In a recent issue of the Paris "Le Temps," the young French naval officer who has made such a brilliant record as an aviator under the pseudonym of André Beaumont, discusses the present status and future possibilities of the aeroplane as a factor in naval maneuvers. We take pleasure in reproducing here the greater part of this interesting exposition, omitting some introductory remarks of a biographical character, and taking up the author's words at the point where he enters upon his main theme.—ED.

Must we seek for marine service the ideal machine which takes flight from the earth, poises itself upon a troubled sea, renews its flight unharmed, executes maneuvers about the fleet, and then at will returns to land or casts anchor in port?

Unfortunately such a machine does not exist to-day, and I am afraid it will not be produced for a year or two, despite the laudable efforts of our constructors, and meanwhile must we be deprived of the aid of aviation in the marine?

To my mind that would be a mistake, and we should be depriving ourselves of an auxiliary already powerful and capable of becoming redoubtable if handled with the skill and daring which have always been among the professional qualities of sailors.

Why wait for future progress when the actual state of affairs is so satisfactory?



Let the constructors continue their researches; let us help and encourage them, and, if necessary, undertake parallel studies in the navy. Let us urge experimental trials, but let us begin by adopting the actual machine that we may profit immediately by the progress attained.

Let us consider how the machine of to-day can be of service. We can have in the first place the "coast aeroplane," which, rising from a point of departure in proximity to a port of war, could fly out to a great distance over the water (30 miles, for instance), and, mounting to a great height, from 1,500 to 4,500 feet, according to the clearness of the atmosphere, descry upon the distant horizon the presence of a hostile squadron or a fleet of torpedo boats. It could observe the number, strength, formation, and direction of the enemy, and in less than an hour and a half return with a report which would at present require the employment of two or three cruisers, or ten torpedo-boat destroyers, and two or three times as great a lapse of time.

Then there is the search for submarines or mines placed by the enemy in the channels of safe exit from ports. The recent experiments of the aviator Aubrun at Cherbourg have shown that from a height it is possible to see a considerable depth down into the water.

The "aeroplane of the high seas" would be capable of a mission of larger extent and greater radius than the coast aeroplane. This is the machine belonging to a specially equipped convoy boat (*not* a man-of-war). The aeroplane rises from

Ideal artificial lighting for a gallery, intensity of illumination practically uniform, light is directed to the walls, not the floor.

Excellent natural lighting obtained by the use of a prism-shaped monitor skylight with opaque top and diffusing glass sides.

Indoor Lighting, Natural and Artificial

Directed-indirect Illumination for Art Galleries

By Putnam A. Bates

EXTERIOR lighting involves problems of a quantitative character, whereas interior illumination is more qualitative, and while both are important, the successful solution of the interior problems has perhaps the greater practical value; for it is obvious that while indoors our eyes are subjected to greater stress.

Apparently there is no reliable and clearly defined record which will guide us in providing both natural and artificial conditions of illumination closely corresponding to those under which the eye is most capable of rendering its best service. At least an exhaustive search, in connection with which the writer has assisted, failed to produce any real data or indication of previous thorough and logical analysis, and consequently, in undertaking the illumination problem of an important exhibition picture gallery recently erected, it became necessary to inspect many of the existing buildings of similar nature, after which it was deemed advisable to approach the problem on entirely new lines.

While this article, therefore, will be confined largely to a description of the solution of the particular problem undertaken, there is much information brought out in the analysis that applies directly to the illumination of almost any kind of an interior, the principles, of course, being observed, rather than the exact arrangement or construction.

Quite to the writer's astonishment, no one seemed to possess the key to the whole situation, although many persons who were interviewed seemed to appreciate, in a rough way, the defects noted in the existing buildings. Daylight illumination has received a good deal of study in reference to special interior problems, but the records do not show that these investigations have been carried sufficiently far for us to learn from them the intensity of illumination that pictures, for example, should receive, or the best relative intensities for the various fired surfaces, ceiling, walls and floor, of a given room. Incomplete as were the daylight experiment data, the results from previous attempts to provide scientifically correct artificial lighting proved to be even more unsatisfactory. Before enumerating several of the violations most frequently committed, I will mention briefly a few of the principles governing the subject of light and its effect upon the human eye.

Through many ages, the human eye has accumulated the characters wrought upon it by evolution and the limitations of its environment. It works best over a rather limited retinal area and through a range in intensity of light which, although great, is yet much smaller than, for example, the extreme variations in brilliancy provided by the sun's rays. Everyone is familiar with the distress caused the eye by sudden alternations of light and darkness, and it seems to be well established that the discomfort caused by the reflected glare from sand, water or snow is due to the inability of the rather transparent lower eyelid to obstruct sufficiently the light that approaches the eye in an upward direction, a condition to which the human eye is not naturally accustomed. All these matters are of importance to consider in connection with interior lighting, and the subject of the following serves as an excellent illustration.

Visitors view pictures to study their relative merits, and are often so absorbed in this, as not to realize, until afterward, under what trying conditions their eyes have been used. The lighting of a picture gallery or exhibition room differs from other interior illuminating problems, but the underlying principles may, nevertheless, be otherwise applied when they are once appreciated. First, the main objective is to provide an illumination which will enable persons to view exhibits with the least possible discomfort or effort to the eye; second, the exhibits will be on the walls and, therefore, the light must be directed there; it, however, must be diffused; third, should the floor be especially bright, or the source of illumination in the field of vision, there is a physiological effect exerted upon the eye which makes the careful viewing of objects not only difficult, but most tiring.

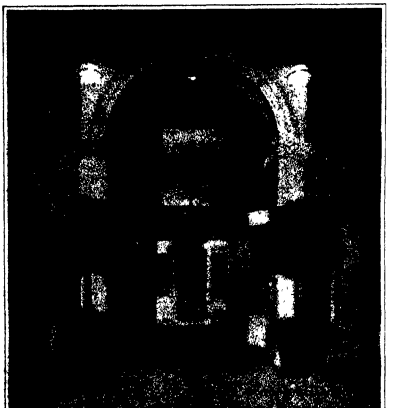

Fig. 2.—Lighting that does more harm than good.

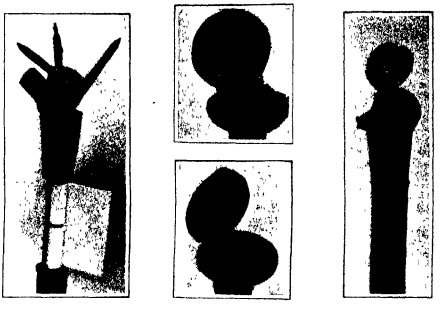
The most suitable intensity of light and the seemingly contradictory requirements that it must be both directed and diffused are difficult conditions to establish, but it is obvious that in every picture gallery or exhibition room the need for solving these essential points has been felt. How frequently do we see the gallery skylight provided with a roller shade or an opaque canopy placed in the center of the room, under which observers may stand to view the pictures without exposure to the direct effects of the entering light. These are but makeshift methods of regulating the intensity, and by negative means, directing the light. Until most recently, however, these devices were regarded as essential features of gallery equipment.

An interesting feature of this situation was, that the results desired, as indicated by these makeshifts, were quite correct, for as one eminent critic described the situation, "the best results would be obtained if in some way the direct rays of the sun's light could be shut out, but the remainder of the daylight be admitted through an overhead skylight, and each visitor be provided with an open umbrella to hold over his head while viewing the pictures." This was the remark of an artist whose knowledge of science and physics was limited to his original observations, but his expressed idea conveyed to the writer that the full range of the sun's brilliancy was vastly too great, and its effect should be modified to correspond more nearly with the limitations of the human eye, and the largest portion of the entering light should be directed toward the walls and not allowed to fall directly on the floor, as is generally the case, where the hung canopy is not used. The canopy, however, is not a desirable intrusion at best, but it is often used to obstruct the downward flood of light which is sure to enter when the sun is high and the surface of the glass area is entirely skyward, a mistake in roof design heretofore almost universally made. It is nevertheless a fact that in spite of its unsanitary objections and unsightly appearance from a lighting standpoint, the presence of the hung canopy is to be preferred in galleries or exhibition halls where the skylight is so constructed. Hence the manner in which the light is admitted is all important.

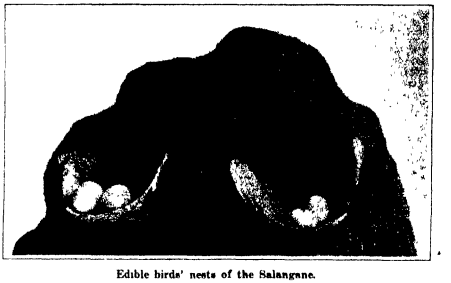


The area of the glass opening in the gallery ceiling governs the amount of light that can be admitted, but the shape of the superstructure or upper skylight practically determines the manner in which the light shall enter. Although well above the room in which the exhibits shall be, this "superstructure" should be most carefully designed. Its top must be opaque so

(Continued on page 397.)

Curiosities of Science and Invention

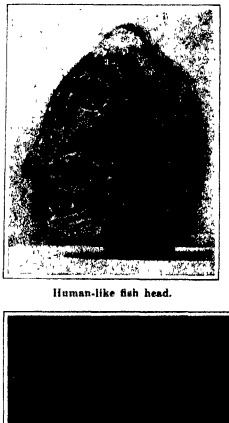
What French Walking-sticks Contain



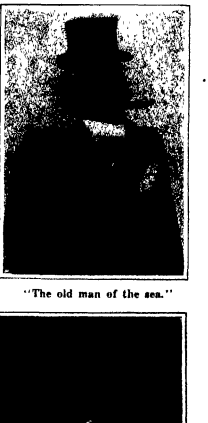
Some time ago we illustrated a number of French walking-sticks which were armed with weapons of various kinds ranging from daggers to rifles. The ingenuity of the Frenchman has not been confined to the making of weapons out of apparently harmless canes. In fact there is quite a variety of uses which the cane is made to serve. In the accompanying series of photographs, some of these are shown. In the figure to the right is a cane fitted with a coin box and a match box, these being contained in the head which is provided with a carefully concealed lid. The coin box is arranged to permit of depositing and easily removing the coin by a slight pressure of the thumb, thus obviating the necessity of fishing for coins in the pocket. The upper one of the two central figures shows a cane handle containing a complete outfit of the game known as Petits Chevaux. When the lid is open, betting can begin, and the horse crossing the wire first wins the stakes. One of the latest Parisian novelties consists in a ladies' parasol handle containing a roulette wheel which can be used for gambling at any place or moment. These handles have become very popular. They are of fine workmanship and generally of gold or silver. The last of the series shows a handle containing almost everything that one would be likely to need. A long sheet of paper is wound around the rod from which pieces may be torn off for taking notes. When the lid is opened penknife, pencil, nail file, combs and looking glass are disclosed. These objects are small, but large enough for practical use.

French walking-sticks and parasols serve many uses.

Edible Birds' Nests

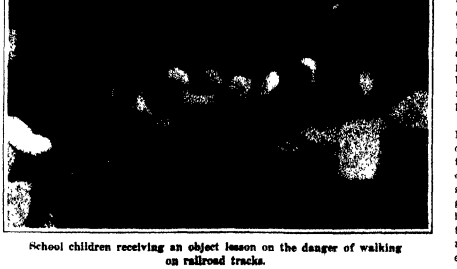


THE uninitiated are apt to think of birds' nest soup as a most disgusting stew of twigs, feathers and what not. As a matter of fact, the nest used by the Chinese is a very delicate semi-transparent gelatinous substance, built by the swallow-like birds known as the Salangane. The nests are found in the islands about Siam and the Malay Archipelago, and the harvest in the year 1909 was 18,000 pounds, valued at over $100,000. It used to be thought that the nest was formed of inspissated saliva secreted by the highly developed glands of the bird. Now it is known that the nest is made of a species of alga gathered by the bird. The season for harvesting the nests lasts from April until September. It takes three months to build the first nest, and just before the eggs are laid the nest is stolen by the collector. The bird immediately sets about the building of a second nest, taking thirty days for the work. This is also stolen before the eggs are laid. The third nest, however, is unmolested and the birds are permitted to raise their young after which the nest is taken and sold. The nests are built in most inaccessible spots upon the cliffs along the coast and the natives must risk their lives to reach them. In preparing birds' nest soup the nest is washed in cold water and then cooked for eight hours in a closed vessel, after which it is mixed with chicken broth, seasoned and boiled for a quarter of an hour. This dish is considered a great delicacy among the Chinese, and Occidentals who have tried the soup find it very palatable and much resembling chicken soup.



Edible birds' nests of the Salangane.

The Old Man of the Sea



PROBABLY one of the most curious of all the marine creatures that have been brought to light in recent times is the fish head here shown, possessing a startlingly human-like appearance. "The old man of the sea," as the fish has been dubbed, was picked up in the waters around Cape Town, Africa. The realistic photographs shown were made at the New York Aquarium. The head was not manipulated in any way. The ragged outline at the back of the head shows where it was severed from the body. The lines on the lower part of the face are natural and are the outlines of the maxillary and other bones of the jaws. The nose has shrunk somewhat in drying. In life the resemblance to the human face was even more striking. The conical front teeth are shown in the photograph. The lateral teeth are very strong and molar-like, evidently for the purpose of crushing shells and, like the famous king of the Cannibal Islands, "he has two rows in his lower jaw." Photographs of the head have been sent to a number of well known authorities on Ichthyology in America, Europe, and Africa for the identification of the species.

Fatalities to Trespassers on American Railroads

THE number of lives lost in wars today, with fighting continually going on in some corner of the world, is nothing as compared with the annual record of fatalities due to trespassing on American railroads. Ignorance or carelessness on the part of the trespasser is responsible for most of this. The railroads are bending every effort to cut down the awful toll of death by posting signs and maintaining police patrol, but they will never be completely successful without the cooperation of the general public.

Every densely populated industrial center near a railroad is a death center. The working classes in crowded districts, and tramps, furnish the majority of victims. Railroads say people must be taught to have more respect for their lives and safety.

With education of this kind in view, the Pennsylvania Railroad is preparing *pamphlets* in eight or nine languages. These will be distributed in schools with instructions to the pupils to take them into their homes. The Board of Education of the State of Pennsylvania has promised its aid. The assistance of clergymen has been solicited, and from hundreds of pulpits the danger of trespassing has been preached. From the good roads trains run through rural districts, and in the farmers' granges the warning has been sounded.

As a result of the education movement and a vigorous campaign against tramps, the number of persons killed while trespassing on the Pennsylvania Railroad's property in violation of the law, has been gradually reduced from 887 in 1905 to 585 in 1910, and the number of injured has fallen from 794 to 682 in the same time. To put these figures in another way; in 1905 the railroad was killing trespassers at the rate of three a day for five months of the year, and two a day for the remaining seven months, while in 1910 the number sacrificed had decreased to two a day for seven months, and one a day for the other five. Railroads are perhaps the greatest sufferers from the tramp evil, and they are willing to do all in their power to stamp it out, but this cannot be accomplished until the citizen realizes the seriousness of the matter and takes his part in the campaign.

Until this country follows the lead of Europe in the matter of legislation to check vagrancy there can be no satisfactory cure for the evil, but if the small communities will punish offenders, instead of passing them along, it will be greatly ameliorated. By doing this, and by aiding the railroads in their campaign to educate the public against trespassing, more loss of life will be averted than by establishing world peace.

Engineering

Record Cargo on the Pacific.—The carrying power of the large freight steamer is well illustrated in the cargo of the steamship "Minnesota," which will sail from Seattle next December with a cargo which establishes a record in the Pacific trade. She will carry 16,000 tons of flour and 2,000 tons of general merchandise, every cubic foot of her tonnage space being occupied.

Towing Locomotives for the Panama Canal.—The Isthmian Canal Commission will shortly advertise for bids for an experimental towing locomotive for towing steamers through the locks of the Panama Canal. Should this machine be successful, bids will be asked for thirty nine more. Four locomotives will be used for each vessel, one on each bow and one on each quarter. The locomotives will run on rack railways, and they will be sufficiently powerful to hold the largest vessel in absolute control.

The Ram a Terribly Destructive Weapon.—Although it is considered that the ram will rarely be used as a weapon of attack in future naval conflicts, there can be no denying its destructive power. A recent survey of the "Olympic" in the dry dock of Harland & Wolf shows that there is a triangular hole in the ship's side reaching from a point 14 feet above to 30 feet below the water line, which will take from six weeks to two months to repair, and will cost about half a million dollars.

Slides at Gatun Locks.—The excavations for the Gatun Locks have caused slides of some magnitude to occur, and the removal of the material will cause a delay of some four months' time. As usual, the occurrence of a slide has provoked alarming rumors, and, as usual, the trouble has been greatly exaggerated. As in the Culebra Cut, so here, the material is of an unstable nature, but when the difficulty has been met as it will be, the construction of the locks will proceed, and once the concrete work is in, all trouble from earth movements will have ceased.

The Reconstructed Battleship "Oregon."—None of the older battleships of our navy is better known or has a more sentimental interest for the American people than the battleship "Oregon," whose voyage around the world terminating in her active participation in the battle of Santiago, will long be remembered. This ship has been undergoing a thorough reconstruction and she is now being given exhaustive tests to ascertain her effectiveness for modern war duty. Particular attention will be given to her new fire control system, to the wireless apparatus, and to other modern equipment.

Navy Yard Reforms. As the result of Secretary Meyer's recent visit of inspection among the European navy yards, he has decided to make a tentative adoption at the Norfolk yard of the system of yard management which is in force at the yards of Vickers Ltd., Barrow-in-Furness, England. This system has been worked out by the Vickers firm along the general lines of scientific management of which we have heard so much lately in this country. In the opinion of the Secretary, it is better adapted to conditions in our yards than the admirable but elaborate method known as the Taylor system, which has tended to provoke rather serious opposition on the part of the labor unions.

Russian Naval Activity.—The dreadnought "Gangut," the fourth of the powerful dreadnoughts which Russia is building in the Baltic, was recently launched. This vessel is one of a class of four ships, including the "Gangut," the "Petropavlovsk," the "Sevastopol," and the "Poltava." These vessels are of 22,300 tons displacement, and their distinctive feature is the method of carrying the main battery of twelve 50-caliber, 12 inch rifles. These will be mounted in four three-gun turrets, one forward and one aft on the center line and one on each beam, the two beam turrets being placed diagonally. This will give a theoretical concentration of fire greater than that of any other ship, namely, nine 12-inch ahead, nine astern, and twelve on each broadside.

Fender Chains at the Gatun Locks.—The character of the bids which are being asked for work on the Panama Canal indicates how nearly this great work is approaching its final stage. Proposals have been asked for materials for the heavy chain fenders for preventing ships from running into the lock gates with which all the locks will be provided. Ships will not be allowed to navigate the locks under their own steam; but should they escape from the control of the towing locomotives, they will be prevented from running into the gates by massive chains stretched across the lock, and controlled by powerful hydraulic cylinders, which will exert a resistance represented by 750 pounds to the square inch on the pistons. A 10,000-ton ship running at four knots an hour, striking the fender chain, would be stopped in a distance of 72 feet 6 inches.

Science

Lamps for Lighthouses.—The use of electric lamps for lighthouses presents certain disadvantages. It is therefore with some interest that we follow the course of some experiments in France on the use of a new kind of incandescent light for lighthouse purposes. The lamp in question has a number of filaments mounted somewhat after the fashion of the filaments of an incandescent gas mantle. In this way a very strong light is secured, which, moreover, has the desirable property of being very uniform in all parts of the circumference. According to recent trials the new type of lamp gave twenty times as much light as a Welsbach burner and required very little attention. The lamp is particularly adapted for shore lighthouses which are easily placed in communication with electric light mains.

Improvement in Incandescent Gas Lighting.—Experiments are at present in progress in Paris as the result of which it is hoped to secure an increased light efficiency from incandescent gas burners. Under present conditions, the gas pressure in the mains is sufficient to draw a certain amount of air into the burner, where it becomes mixed with the gas, causing the characteristic blue flame. But the amount of air thus drawn into the flame is only about three times that of the gas, whereas, for the best effect, the ratio should be five to one. It has been found that by compressing the gas in the mains the desirable ratio of air can be caused to enter the flame. One of the boulevards in Paris has lamps working on this system, and the results are exceedingly satisfactory.

Electric Light for Sterilizing Milk.—We read in a Daily Consular Report a note from Consul Mahin, of Amsterdam, according to which a local periodical refers to the effect of ultraviolet beams on bacteria and to the fact that such beams are abundantly developed by mercury incandescent lamps and relates that through this medium milk may now be sterilized in a few minutes. An apparatus has been constructed, it is explained, whereby the milk flows in a thin stream along an electric light. Demonstrations were first made with water infected with different kinds of bacteria and it is said that the water was purified in a few minutes without appreciably increasing its temperature. The result is attributed to the ozone formed under the influence of the light, but the demonstrations must be conducted where there is sufficient room for the light to burn freely. This method of sterilization without heating or adding preservatives, is believed to have great hygienic value in respect to nursing children.

The Influence of Dust on Mortality.—Out of every thousand of those whose occupation calls for constant work in dusty quarters, five die of consumption according to German official figures, whereas among those who are not exposed to the action of dust, only two out of a thousand die of the disease named. As regards the comparative danger of the different sorts of dust, the following figures will prove instructive:

KIND OF DUST	
Metallic	
Iron	6
Lead	8
Mineral	
Stone	35
Porcelain	14
Organic	
Leather fur and feathers	5
Wool and cotton	5
Wool and paper	6
Tobacco	7
Total	86

Influence of Room, Light and Fresh Air on the Growth of Children.—To show the influence of room, light and fresh air on health and growth, the following figures are given, concerning the height and weight of boys in Bourne Village, England, as compared with those in Birmingham slums. Bourne Village has 840 houses, distributed at the rate of only nine to the acre; at the time of making up this table, the population was 4,000.

Weight of Boys (pounds)

Age, years	6	8	10	12
Bourne Village	45	52 9	61 6	71 8
Birmingham slums	39	47 8	56 1	63 2

Height of Boys (inches)

Age, years	6	8	10	12
Bourne Village	44 1	48 3	51 9	54 8
Birmingham slums	41 9	46 2	49 6	52 3

The death rate (average of five years) is for Bourne Village 8.5 and for England and Wales 14.9, per 1,000. The infant mortality (average of five years) is for Bourne Village 68 and for England and Wales 121.8, per 1,000 live-born children.

Electricity

Royal Experiments in Wireless Telegraphy.—King Albert of Belgium is keenly interested in wireless telegraphy. He has a complete radio-telegraph equipment in his palace at Laeken where he is fond of conducting experiments.

Hydro-electric Power for Constantinople.—Constantinople is soon to be supplied with electricity from a hydraulic power station on the Sakaria River, 80 miles away. Here two turbine stations will be built, one of 15,000 horse-power using a 180 foot head of water and the other of 8,000 horse-power, employing a head of 120 feet.

Electric Railroads in the Pyrenees.—About 500 miles of railroads are being built in the Pyrenees. These railroads are to be operated by electricity which will be furnished from water power stations in the mountains. Power will be supplied at a voltage of 6,000 volts, which will be stepped down to 12,000 volts for the trolley wires. The locomotives will be provided with transformers for further reduction to 285 volts.

Novel German Transmission Poles.—A novel type of reinforced concrete pole is now being used in Germany for transmission lines. The pole as perforated from the top to a point near the base. The perforations are large enough to permit of inserting the foot so that the lineman does not require climbers to reach the wire brackets at the top. The poles are thus virtually given the form of narrow ladders.

Wireless-Controlled Submarine.—According to a recent press report some interesting experiments have been conducted by the British navy in the control of submarine boats from cruisers. These experiments have been kept very secret but it is known that a submarine boat in the waters off Solent was controlled by wireless telegraph apparatus aboard the cruiser "Furious." Experiments were also conducted with torpedoes controlled by Hertzian waves.

Electric Power from Water Supply.—The Wachusett reservoir, which supplies Boston with water has a capacity of 68,000,000 gallons. The reservoir is located 395 feet above the level of Boston and as a 300 foot head is considered ample for the city the balance is to be used for the generation of power. A hydro-electric plant comprising four turbines of 1,000 kilowatt capacity, has been installed. The plant has cost $125,000 but the current it will supply should bring in a revenue of $25,000 per annum.

Overhead Alternating Current on Swiss Railways.—After seven years of study, a commission appointed by the Swiss Republic to investigate various methods of electrification has decided to recommend the overhead rather than the third rail system for the Swiss National Railways. There will be 1,830 miles of railroad in the Swiss system and it recommends that a single-phase alternating current be used at a pressure of 15,000 volts. The cost of the entire system will be about thirteen million dollars.

Electric Trucking.—In his presidential address before the Electrical Vehicle Association of America Mr. W. H. Hood Jr., referred to the fact that the average amount of freight handled on the streets of Boston per day amounts to 25,000 tons and that the total freight carried by wagons in the United States is more than ten times as much as that carried by railroads. He pointed to these facts as indicating a large field for motor trucks in this country and stated that were this freight handled by electric power it would require three million power wagons.

Battery Truck Crane.—There has been a demand at great railway and marine terminals and in manufacturing plants for a device for handling freight and materials over moderate distances. To meet this demand an electric motor truck fitted with a swinging crane has been designed by the General Electric Company. The crane's hook is raised and lowered by a one ton hoist driven by a motor which together with the motor that operates the vehicle is supplied with current from a battery. The motor truck crane is mounted on traction wheels and has a short wheel base so that it may make sharp turns about shop aisles and among piles of material in congested piers and storage yards.

Storage and Primary Batteries.—According to a preliminary report issued by the Census Bureau the value of the storage and primary batteries manufactured increased from $3,679,000 in 1899 to $14,244,000 in 1904 and $10,612,000 in 1909, or 188 per cent during the decade. Both storage and primary batteries consist of various elements which are not always combined and sold together as a unit by the same manufacturers, and yet it is not until these are brought together that a complete cell is constituted. Many of the parts and supplies used are manufactured outside of the electrical field and therefore the statistics shown in this report do not convey a correct idea of the importance of this branch of the industry.

Dropping Bombs from Flying Machines

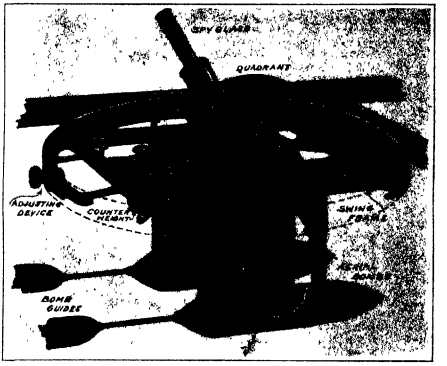
The Aeroplane as an Offensive Weapon of Warfare

By Riley E. Scott, formerly Lieutenant U. S. Army

IN this age of scientific armament, every new invention that bears at all upon the art of warfare is carefully weighed in the balance of military usefulness. The balloon, telegraph, telephone, automobile, motorcycle and more recently, wireless telegraphy, have all demonstrated their ability to further the dread game of war and have, consequently, been added to the standard equipment of armies. While enthusiasts are heralding the advent of universal peace, the silent, non-sentimental sentinels of warfare are eagerly acquiring every device and invention that may give them an advantage in the next clash of arms—perhaps the world's greatest war!

To the military man, warfare is a science, no sentimental theories or fancies enter into his cold calculations, no "dream of the ages" appeals to him unless it can add to the efficiency and destructiveness of his engines of war. Consequently, when word went round the world that man had flown, that a heavier-than-air machine had actually risen from the ground, military authorities did not let enthusiasm run away with judgment; they placed a "watch" on this new invention and the more progressive nations took steps to test it carefully with a view to its use in warfare. Within less than three years, its usefulness, even necessity, for scouting and reconnaissance work has been proven beyond a doubt and in consequence, the aviator has taken his place in the military establishment and aviation corps have become a part of the organization of armies. From developments in recent maneuvers, it is safe to predict that, in the next great war, the initial battle-clash will be between squadrons of scouting aeroplanes and that many a deed of devotion and daring will inspire the pen of the future historian.

Much has been said and written lately about the use of the flying machine as a destructive weapon. "Bomb" dropping has been a popular feature of recent aviation meets and enthusiastic reporters have given their imaginations full rein, with the result that cities have been destroyed, forts demolished and battleships sunk. It must be observed, however, that all such tests have been made from heights of three hundred feet or less, at which range an aeroplane would not have a ghost of a show against machine guns, shrapnel, rapid fire guns or even rifle fire. When we consider aeroplanes flying at reasonably safe heights say between one and two miles the problem of accurately dropping projectiles becomes a difficult one and scientific calculation must take the place of guess-work.



Granting that a reasonably accurate method has been or will be developed for dropping projectiles, let us inquire what damage can be done.

1st. Against Armies.—At the beginning of a battle usually about one-third of the troops are on the firing line in extended order, while the remaining two-thirds are massed in supports and reserves in the rear of the firing line in positions offering the best protection from the enemy's fire. These supports and reserves are massed in close order, they cannot be greatly extended for the commanding general must have them under his thumb in order to quickly reinforce weak or threatened parts of his firing line at any time. Still farther to the rear are the wagon trains, artillery parks, lines of communication, supply depots, etc. An aeroplane operating against armies in the field would, therefore, probably use *shrapnel*, an explosive shell filled with hundreds of bullets and equipped with a time-fuse in such manner that it can be exploded above bodies of troops on the march, supports, reserves, wagon trains, camps, etc. Shrapnel is considered one of the most effective projectiles used in modern warfare, and it does not require a military expert to imagine the havoc it would work on a body of troops *en masse*. Moreover the moral effect of such a weapon would be tremendous.

2nd. Against Cities.—In operations against cities, aeroplanes would use incendiary bombs, small bombs filled with some material which would set fire to combustibles on contact. Dozens of such bombs could be carried and a few aeroplanes could soon start a general conflagration. Any activity on the part of the fire department could be quickly dampened with a few shrapnel.

3rd. Against Fortifications.—Any one familiar with sea coast fortifications knows that the accuracy of the big guns mounted there depends altogether upon the range-finding system. These systems are of two kinds, horizontal and vertical. Both systems depend upon more or less delicately mounted instruments, mounted in buildings screened and protected from the harbor but not from the *sky*. In fact, they must be above the parapet so as to get an unobstructed view toward the harbor. Consequently, it would not be necessary to pick out the separate emplacements and guns for destruction, it would only be necessary to drop a steel projectile filled with high explosive, lyddite, for instance, on or near the range-finding bases. These being out of commission, the costly guns become as useless as so much junk. Magazines, barracks and store-houses could also be destroyed.

4th. Against Battleships.—The most difficult target for an aeroplane would probably be a battleship, on account of its relatively small size and its rapid movement. Night attacks and attacks while at anchor would probably be the most usual, although, in a naval

An instrument for directing bombs from aeroplanes.

battle, aeroplanes would be able to do much to harass the enemy. A few well placed shrapnel exploded above the gunners would not tend to increase their accuracy, and, better, smoke bombs exploded to the windward would do much to destroy accuracy of aim. Then a high explosive would be used, and, unless protective decks are materially strengthened, would be terribly effective. Authorities to the contrary notwithstanding, the writer holds that a steel projectile filled with 200 pounds of high explosive, striking with a velocity of 500 feet per second, even though it should not penetrate the protective deck, would work terrible havoc to a battleship. Present development points to the early construction of aeroplanes that will be able to carry a load of 1,000 pounds to a height of a mile and remain there for several hours.

On the other hand, those who have studied the question carefully believe that an aeroplane flying at heights greater than one mile will be a very difficult target, indeed, for gunners on the ground. Some of the reasons for reaching this conclusion are as follows:

1st. The aeroplane is not confined to movements in a horizontal plane, but may move in any plane. Those familiar with the subject know that, in order to hit a moving battleship from a seacoast gun, it is necessary to plot ahead and lay the gun ahead of the ship, just as a shot gun is held ahead of a duck. With a swiftly moving and, probably, zig-zagging aeroplane, it will be much more difficult to plot speed and direction and lay ahead than in the case of a battleship.

2nd. The difficulty of accurate aiming in high angle fire is generally recognized.

3rd. Refraction, or the bending of light rays from a rarer to a denser medium, will complicate matters.

4th. Projectiles fired at a very high angle, especially at aeroplanes hovering over an army in the field, will return to the vicinity from which fired, whether the target is hit or not.

5th. An aeroplane in close quarters would probably drop smoke bombs to obscure the enemy's vision, on the principle of the cuttlefish.

However opinions may differ, the rapid development of the aeroplane for military and naval purposes, especially in Europe, behooves us to consider it most seriously in the problems of seacoast and canal fortification that now confront us. We like to boast of our splendid isolation, of the steel throated monsters that guard the entrances to our harbors. Suppose, for instance, that, ten years hence, every battleship is equipped with flying machines; also, that an enemy's fleet appears fifty miles off New York. Would it be necessary to pass our forts in order to destroy the metropolis? Hardly; a fleet of aeroplanes would be despatched; within an hour they would be over the city; obeying wireless orders from their commander, they would maneuver over the thickly built section and soon it would be a mass of flames. Fantastic? Possibly so; but, in view of the recent extensive and successful use of the aeroplane in European maneuvers and, also, of the fact that other nations are spending many millions of dollars for aeronautical purposes, it might not be unwise for our Congress to depart from its usual policy of economy by appropriating a million dollars to enable the army and navy to fully test this new arm. Nations, as well as individuals, are sometimes penny wise and pound foolish.

A careful study of the problem of dropping projectiles reveals a certain relationship to the problems presented in mortar fire. In mortar fire, the theoretical trajectory of the projectile is a parabola, as shown in Fig. 1. Neglecting atmospheric resistance, the ascending and descending halves of the parabola are equal and symmetrical. The apex of the trajectory is a point at which the vertical component of the muzzle velocity has been used up in overcoming gravity and only the horizontal component remains. From this point the projectile falls with an acceleration due to gravity and, theoretically, would strike a target on a level with the muzzle of the gun with the same velocity it had when it left the gun. It is evident that, if an aeroplane should be moving on a level with the apex of the trajectory considered and in the vertical plane containing the trajectory, with a velocity equal to the horizontal component of the muzzle velocity, and should, at the apex, drop a projectile of the same weight, size and shape as that of the mortar, the projectile thus dropped would take the identically same path and strike with the same velocity as the mortar projectile. In other words, the problem is similar to that of mortar fire and only one-half of the trajectory has to be taken into account.

Briefly considered, the mathematical aspects of the problem are as follows: If an aeroplane, moving horizontally *in vacuo*, with a velocity of, say, 20 meters per second, should release a projectile at a point, *A*, Fig. 2, the projectile would take a parabolical path whose form and equation would be determined entirely by the height of the aeroplane and its speed with respect to the surface of the earth. The general equation of such a parabola is readily calculated and is, $x^2 = \frac{2v^2}{g} y$; in which x is the horizontal distance in front of the target at which the projectile must be released; y is the height above the ground; v is the velocity of the aeroplane with respect to the ground; g is the constant of gravitation for the particular place. Knowing all the factors in the second member of this equation, the value of x is readily found. This gives a right angle triangle, *AOT*, Fig. 2, in which, knowing x and y, the angle, α, at which a line of sight (telescope) in the vertical plane containing the target must be set in order to strike the target, *T*, can be readily computed. Each velocity of the aeroplane and each height will, when substituted in the above equation, give a different triangle and, con-

sequently, a different value for the angle, *a*. Substituting for every possible height and every possible speed will give a series of values for this angle which may be easily tabulated.

This discussion has considered the projectile in vacuo. It is apparent that the resistance of the atmosphere will depress the trajectory, as shown by the dotted lines in Fig. 2. Consequently the table above referred to would have to be corrected for atmospheric resistance and additional correction-tables constructed for winds and hygrometric conditions. Such correction tables would be relatively simpler than similar tables used in artillery and naval practice.

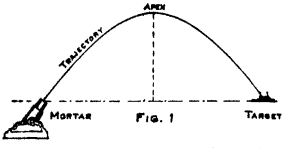


FIG. 1

A patented device, of which the writer is the inventor, takes scientific consideration of all the factors that enter into this problem. This device consists of a series of concentric rings universally mounted (that is, mounted on gimbals at right angles to each other) The center of gravity being considerably below the center of support, the inner ring assumes a horizontal position when symmetrically loaded. A telescope, with graduated arc and vernier, is mounted on the inner ring at right angles to the plane of the ring. The line of sight of this telescope therefore describes a vertical plane when revolved, enabling the operator to lay off the angle, *a*, for the particular height and speed used. Consulting Fig. 2, it is evident that, when the line of sight intersects the target, *T*, the projectile should be released

In order to solve the equation above given, it is

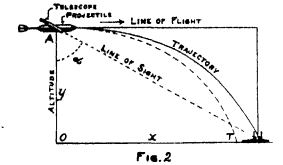

FIG. 2

necessary to know *v*, the velocity of the aeroplane *with respect to the ground* There is no instrument for measuring this velocity, it can, however, be readily determined by using the device above described

Consulting Fig 3, it may be seen that, when the angle *a* is 45 degrees, the distance *y* equals distance *x*

Therefore, in order to determine the speed over the ground, set the telescope at 45 degrees from the vertical and fly horizontally Knowing the height from the barometer, note when some conspicuous object, as a tree, crosses the field and start a stop-watch Then revolve the telescope to a vertical position and continue the flight to *B*, at which point the tree will again cross the field At this point, stop the watch

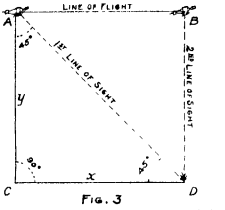

FIG. 3

The speed over the ground will equal the height divided by the elapsed time These speeds may be tabulated by taking all possible heights divided by all possible elapsed times It is apparent, also, that the whole operation will take scarcely more than a minute unless the height is very great

The "Hawke"-"Olympic" Collision

Experimental Investigation of the Cause of the Disaster

By Robert G. Skerrett

THE British naval authorities and the officials of the White Star Line are seemingly bent upon withholding from the public the essential facts regarding the collision between the "Hawke" and the "Olympic" on the 20th of September. Were the commander of either ship undoubtedly at fault in the handling of his vessel, it is not at all likely that the present policy of silence would be preserved, and this naturally suggests that there were conditions contributive to the mishap which were, in a degree, either unsuspected or beyond control of the commanding officers This suggested a line of investigation which, while not exactly new, is at present not thoroughly explored.

In April of 1908 the "Prinzess Irene" and the steamer "Parima" were outward bound in the lower bay of New York. The "Prinzess Irene" was bound for Europe, while the "Parima" was steaming for the West Indies The two ships were at least 200 feet apart, but following a comparatively narrow channel. Just before reaching a certain buoy, the "Prinzess Irene"—the bigger craft—began to lap upon the stern of the leading "Parima" Suddenly, the latter vessel was drawn to starboard and toward the "Prinzess Irene," while her bow fell off to port despite her helm and engines, and her head grounded There was no collision Some hours later the "Parima" was gotten off, but she was found to be leaking, and repairs costing about $40 000 were needed before the ship could put to sea

It was claimed at the time that the mishap to the "Parima" was due to suction set up between the two vessels in motion while proceeding on the same course. As a result of the unusual mishap Naval Constructor D W Taylor, U. S. N., carried on a series of experiments at the Government Model Basin in Washington. In substance, Naval Constructor Taylor found that when the overtaking ship began to overlap the other the disturbing force was of slight moment: there actually appeared to be a repulsion at both bow and stern, and, strange to say, the repelling forces acting upon the stern appeared to be greater than that exerted upon the bow of the following vessel—causing the stern of the latter to turn in toward the leader. As the over-hauling craft continues to creep up, the bow suction grows stronger, and the repulsion of the stern of this ship lessens—becoming, in fact, attraction when the two boats are abreast. Carrying the action through its natural sequence—the two boats proceeding—Naval Constructor Taylor discovered that there was a reversal of effects as the overtaking vessel assumed the lead: the bow suction diminishing rapidly while the stern became stronger—the latter reaching a maximum when the midlength of the overhauling boat was something like two-tenths its length ahead of the midships of the overtaken vessel. These disturbing forces are particularly potent in shallow waters, and the experiments at the navy yard in Washington were made under circumstances of depths which were calculated to diminish rather than magnify the measure of the suction as compared with the circumstances of ships passing through the ordinary channels approaching harbors Naval Constructor Taylor found by his model trials, when the two boats were in the position described by Prof Reeve, that the forces of attraction and repulsion were, in effect, directly opposite, i e, the bow of the overlapping boat turning in toward the midlength section of the craft afill in the lead

The correctness of Naval Constructor Taylor's conclusions can easily be verified and understood even if one has not at his disposal a model basin for actual tests In Fig 1 we have a pipe of variable diameter through which water is flowing in the direction of the arrows. At the points of maximum diameter, *P P* we have the full pressure of the head, while through the contracted section, *V*, we have increased velocity but *diminished* pressure Bearing the simile of this pipe and the varying pressures due to changes of diameter in mind, we can easily trace the action of the forces at play between two vessels where one is overhauling and overlapping the other In Fig 2, the smaller ship is within a short distance of the bigger leading one and abaft the beam of the latter Both vessels being in motion, the effect of the stream-line forces is a counterpart of current sweeping sternward. The hulls of the two ships form for us the adjacent walls of the pipe, while the relative nearness of the bottom on one hand and the water's surface on the other box in, so to speak, the stream-lines At the point *V* we have a restricted passageway for the current and, hence, reduced pressure and increased velocity of flow. This action may possibly be augmented by the propeller wake of the big ship At point *P* we have full pressure acting against the starboard bow while on the port bow at *V* there is a loss of pressure. Naturally the bow swings to the left and the stern in the opposite direction, drawing the smaller overtaking boat toward the larger one

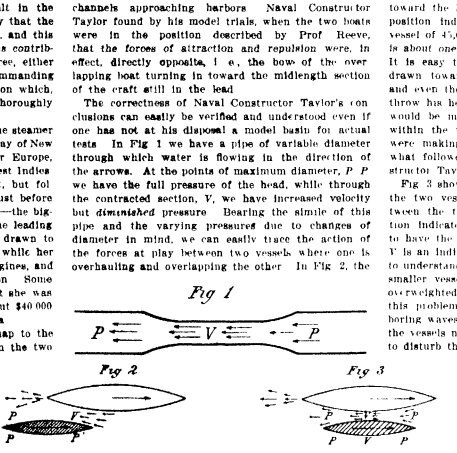

Diagram illustrating the "Hawke"-"Olympic" collision and its cause.

The accounts of the movements of the cruiser "Hawke" just prior to her collision with the "Olympic" seem to agree that the warship was crowded toward the liner and brought approximately into the position indicated by Fig 2 The "Olympic" is a vessel of 45,000 tons displacement, while the "Hawke" is about one-sixth as large and of much lighter draft It is easy to understand how the cruiser would be drawn toward the liner under these circumstances and even though the commander of the "Hawke" did throw his helm over the hydrostatic energy at work would be more than the latter's rudder could offset within the time available—especially if the warship were making considerable speed In Fig 4 we see what followed, and this bears out what Naval Constructor Taylor found to be the case with his models

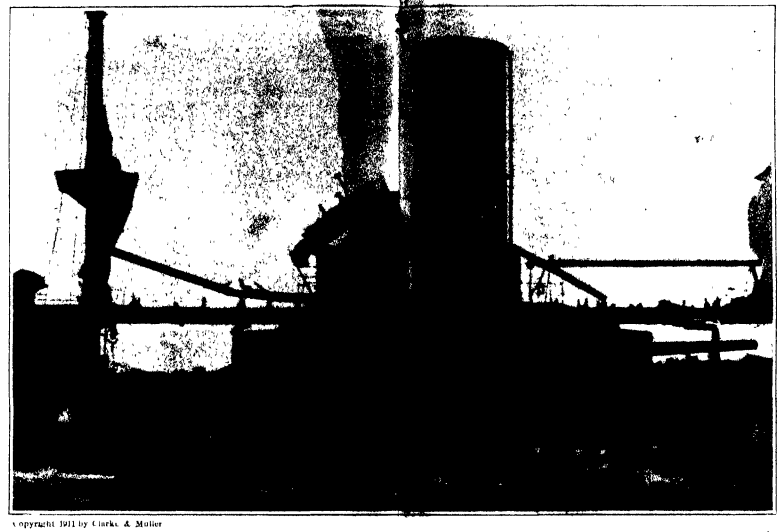
Fig 3 shows us how the forces are distributed when the two vessels are directly abeam The space between the two boats is a counterpart of the condition indicated by the pipe in Fig 1 Assuming *P* to have the same force value in each instance while *V* is an indication of reduced pressure, it is not hard to understand how the resultant is a movement of the smaller vessel bodily to port and toward the bigger overweighted by *P, P, P* It is not necessary to confuse this problem with the crests and hollows of neighboring waves formed by the ships in motion In fact the vessels need not be moving at speeds high enough to disturb the water to this extent in order to arouse the suction needful to draw the vessels toward one another

It is quite likely that the disparity in size between the "Olympic" and the "Hawke" may have contributed to the disaster, because there was also a considerable difference in size between the "Prinzess Irene" and the "Parima" In the experiments made at the Washington Model Basin the models were of identical displacements It is fortunate that the collision between the warship and the liner occasioned no loss of life and if it were due to suction even admitting imprudence on the part of the naval skipper it is but another object lesson on a large scale of the care that ought to be taken under circumstances of this sort We must not forget the immense size of the "Olympic" and the majority of the ships now engaged in transatlantic passenger and freight service, nor must we overlook the steady development of speed in these big vessels Undoubtedly, both of these factors have an important bearing upon this question of suction, and these craft should be given a wider berth when in motion The mishap is fruitful of valuable suggestions and at the same time, it brings us to a realization of the stupendous energy latent in the water when the balance or equilibrium of the stream-lines is once disturbed

A Landsman's Log Aboard the Battleship "North Dakota"—II.

By J. Bernard Walker.

This landsman's log is written by the Editor of the SCIENTIFIC AMERICAN *as a preliminary to a magazine Naval Number to appear early in December, which will be comparable in its size and completeness with the Naval Number issued during the Spanish War. Alone respect it will be unique, for it will be written entirely by prominent officers of the Navy, each a specialist in the particular field that he covers. The leading article, moreover, will be from the pen of the Hon. George von L. Meyer, the Secretary of the Navy. The illustrations will consist of specially taken photographs taken during the recent maneuvers and target practice of the Atlantic Fleet on the Southern Drill Ground.*



Copyright 1911 by Clarke & Muller

"Crash goes the salvo, to be followed some twenty-five seconds later by the truly splendid spectacle of many giant geysers spurting high around the target."

"THE Admiral authorizes you to go aboard the Michigan to witness the firing of the Delaware against the 'San Marcos.' Boat leaves the starboard gangway at five o'clock." I rub the sleep out of eyes that are heavy with that slumber which only the sea can give, and turn to see an orderly disappear with a wireless message in his hand. Where am I? Why is the gray dawn coming through a square hole in the ceiling instead of through curtained windows in the wall? And why is that wall circular? Ah, yes, I am aboard the "North Dakota" and the circular wall at the foot of the bunk is the 10-inch barbette armor of her No. 1 turret (the officers' quarters are forward on this ship) and that 'window' is a square light in her forecastle deck, and those two black cylinders that I see above it are the forward pair of twelves; and ten minutes later I am gulping down a cup of coffee with half a dozen of our officers who have been detailed to the "Michigan," whence they will observe with critical eye the success or failure of the one particular rival of the "North Dakota"—her twin sister the "Delaware."

So we tumble into a steam cutter and a few minutes later are on the quarter deck of the Michigan," whose gun tompions (plugs which close the muzzles of the guns) have already been decorated with the coveted 'E' pennant with a black ball in the center which is carried by the ship that has made the best gunnery score in the annual Spring battle practice. The firing on the 'San Marcos" is to be carried out (as are all the major gun practices of our fleets) with a close approximation to battle conditions, and she will steam past the target "in division," that is to say, she will form one of a line of four ships, with the "Michigan" leading her. The wisdom of this policy must be evident to the veriest tyro if it means that, if ever the test of actual battle comes, it will present conditions with which the ship's company are largely familiar, the vital difference, of course, being the din and shock of such shells of the enemy as may land upon the ship. In the opinion of many naval officers the sound of shells that strike one's ship will be no louder than the stupendous crash of the ship's own salvos, and the shock to the ship as a whole of a striking shell can be no greater, surely, than that of the discharge of her own guns, which, I noted, shook the huge bulk of the ship as by an earthquake and made the masts, in the tops of which I stood, whip to and fro, for a moment, like reeds shaken in a wind. (This vibration lasts but a second or so. Long before the shells reach the target the platform is perfectly steady for observations by the spotters.)

But here, drifting lazily across our bow, comes the "Delaware," fresh from the Coronation Review, where she ranked as the largest and most handsome of the assembled warships. Stripped for action and with the light of dawn glistening down the long, lean length of her, this shapeliest of battleships looked for all the world like a huge torpedo-boat destroyer! The "Michigan" hoists her anchor home, gets under way, and passing to starboard of the "Delaware," leads her out to the course, two other battleships falling in astern to complete the division. We steam past the 'San Marcos," leaving her some miles to port. Soon we are fifteen thousand yards from the mark and still dropping her astern, while the far distant fleet resolves itself into a confused group of smoke-enshrouded masts and smokestacks. Still we keep going, until observations show the sunken ship to be some twelve to thirteen miles distant. The speed is raised to 15 knots, and a faint feather of foam parts at the stem and flows by the keen cutwater of the "Delaware." 350 yards astern. Then, over goes the helm and around swings the "Michigan," leaving a broad band of curiously foaming and twisting water in her wake. Splitting this in its exact center, the "Delaware" follows and in a few minutes we are straightened out on the course.

Copyright 1911 by Clarke & Muller

"Poor old 'Texas'! At one time it looked as if your only mission in the fleet was to get into trouble, and stand as the butt for jests inside the navy and out. Well—you redeemed yourself in the Spanish war, and you have more than redeemed yourself in the information which you have furnished as to the inability of your fabric to stand up under the mighty hammering of modern ordnance."

And now the range-finders are trained upon the faint blotch that marks the position of the "San Marcos," and they tell us that we are some twelve miles from the target. The observer calls out the decreasing distances. "Twenty thousand yards"—"nineteen thousand, five hundred yards." "That is eleven miles," I say to myself, "and she won't be firing her ranging shot for another five or six minutes at least." But, glancing at the ship, I notice one of her forward 12-inch guns is rising slowly to near the maximum elevation of fifteen degrees. "Can it be possible that she is going to open up at a range of over ten miles?" I ask of a young ensign who is sharing a perch with me half way up the after cage mast. I am reaching for my camera when, white and swift as any lightning stroke, there burst a flash of flame from the gun, and the "ranging" shot is off on its ten-mile flight through the air. Up go our glasses on the distant "San Marcos." There is a wait of half a minute (it seems to one's tense nerves more like half an hour) when, apparently right at the wreck, there spurts up a vast geyser of snow-white water 200 feet into the air!

The observers on the 'Panther," which was anchored one thousand yards astern of the "San Marcos," stated that this trial shot landed only 75 yards short of the target! Think of the marvel of it all! High upon half a ton of steel launched into the air from a point about nine or ten miles distant, after describing a vast parabolic curve drops within less than 100 yards of the object aimed at! Then comes another flash—another long wailing cry of the swiftly spinning projectile—and another splash, this time one hundred yards over the target. And now for the salvo. One sees the ten 12-inch guns, which project across the starboard deck, move up like the black antennæ of some Brobdingnagian monster, as if feeling their way to the target. Crash goes the salvo, to be followed some 25 seconds later by the truly splendid spectacle of many giant geysers spurting high around the target. Fast and furious come the flash and the roar of the discharges. Now it is the foremost pair of twelves, then the aftermost, then a four-gun, and then a six-gun salvo. Over half a hundred shots are fired, all within a period of a few minutes, and many of them with an interval of only 30 seconds between rounds.

For the second time that day the courtesy of the Admiral is extended and the ship's cutter takes me over to the "San Marcos" for an inspection of the damage done on this and other days of firing. As I neared the old vessel, my mind went back to a visit made thirteen years ago aboard this ship, at the close of the Spanish war, when her captain took me down to the gun deck and showed me how the blast of her port 12-inch guns had dished the deck above, and showed me also the hole in her port bow, through which a shot from La Socapa battery at Santiago had entered the gun deck and caused one of the very few gunnery casualties of the war.

Poor old Texas! At one time it looked as if your only mission in the fleet was to get into trouble, and stand as the butt for jests inside the navy and out. Did I not see you one morning in the Brooklyn navy yard, lying ingloriously on the soft ooze of the dock bottom, into which you had deliberately settled in the night as the result of some one having left open one of your sea cocks. In those days, about everything in the calendar of mishaps that can occur to a ship seemed to come your way. Well, you redeemed yourself in the Spanish war, and you have more than redeemed yourself in the information which you have furnished to the Service regarding the inability of your fabric to stand up under the mighty hammering of modern ordnance.

As I climbed aboard it came to me that the last time I trod the main deck it was in the company of that fine officer of the older school, Capt

(continued on page 484)

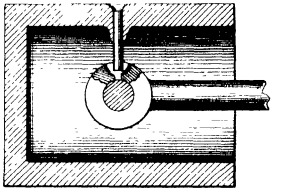
Suggestions for the Workshop

Ingenious Expedients of Resourceful Mechanics



Lubricating a Wrist Pin

By F. E. Keller

OWNERS of gas engines, who have the horizontal type where the wrist pin is oiled by the cylinder lubricator by way of a hole through the shell of the piston, will in some makes of engines find much

The oval oil hole in the wrist pin.

Section through the wrist pin.

difficulty in keeping the wrist properly oiled thus resulting in excessive wear and a continuous knocking. The writer having had this experience, made use of the following kink, which worked perfectly. The hole in the piston was drilled out and a brass tube of proper length was fitted into it, as shown in one of the drawings. The oil hole in the connecting rod was cut to an oval shape to allow for the swinging movement of the rod. In operation the brass tube directed the oil down to the bearing, thus doing away with the splashing out ordinarily caused by the rapidly moving engine.

Carrying Water on Moving Trains or Boats

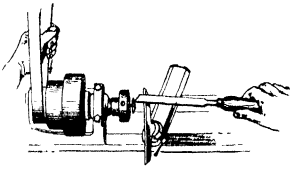
RAILROAD men frequently carry pails of water in the caboose and baggage cars. The motion of the cars would cause the water to slop did they not employ the kink here illustrated. On the water is laid a thin board circular in shape and a little smaller in diameter than the inside of the pail to prevent pinching or jamming. When the baggage master desires to wash his hands he simply presses down the board with his knuckles or finger, which gives him all the water he needs without removing the board. This scheme for carrying water in a pail could be used to advantage on a cruising boat or a motor boat.

The baggage master's pail.

A Spur Chuck for Wood Turning

By William Grotzinger

WHEN the ordinary chuck is used on small pieces of soft wood, there is a tendency for it to split the wood at its center. A spur chuck for soft wood, which will do away with splitting, can easily be made



Spur chuck for small work

according to the drawing. A round channel is filed in the end of the square body of the chuck and a rectangular channel is filed crosswise. The four spurs thus formed have plane parallel outer surfaces, while the curved inner surfaces serve to compress the wood between them, instead of cracking it apart as in other chucks.

Removing the Waste on the Wood Turner's Screw Chuck

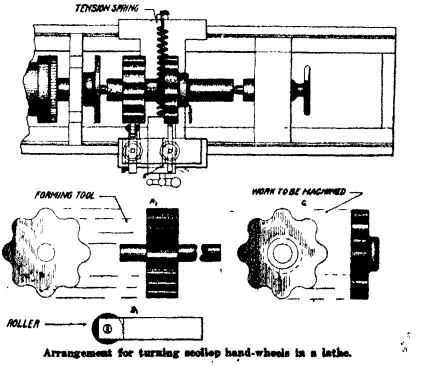
By F. B. Albert

WHEN the wood turner is turning drops or thin rosettes which are fastened on the screw chuck, there is not much wood left to grasp in removing. The wood turner, with the chisel resting on the rest, catches the point in the outer part of the rosette

Removing a rosette from the chuck.

on the back side of the lathe. With a quick pull on the belt with his left hand he revolves the lathe backward which readily unscrews the rosette from the chuck. All the stub pieces which are left on the chuck from other turnings are removed likewise.

Removing a Plug from Blind Holes



THE shank of a drill chuck was twisted off close to the end of the chuck, and it was quite a problem to get the end of the shank out, so the following little kink was tried. A ¼-inch hole was drilled endwise through the broken piece. The hole extended through the plug into the open space at the bottom of the hole. The hole was then filled with oil, and a ¼ inch pin was made, so it would slide freely therein. The pin was placed in the hole, and then was struck a heavy blow with a hammer, causing the oil that was at the bottom of the hole to force the plug out.

Turning Scollop Hand-wheels in a Lathe

By H. D. Chapman

THE accompanying engraving shows a practical little kink for turning scollop hand-wheels in a lathe. The writer once had a large number of hand wheels to be made as shown at *C*. The wheels were made of bronze and were cast. The outside diameter was to be machined so the job would look mechanical and it required too much time to file the wheels up, so this tool was devised.

The forming tool *A* was made of machine steel to the exact finished size of the hand wheel. A roller *B* was made of tool steel, and was of the same diameter as the radius of the scollop in the hand-wheel. Some slight changes were necessary in the lathe to accommodate the working of the tools. The feed screw on the cross-head of the lathe was removed and a coil spring was run from the cross-head of the lathe to the back of the carriage. This spring was made of No. 10 B & S wire, which was strong enough to control the cutting of the tool. A double tool post was rigged up and placed on the cross of the lathe carriage. The work was then mounted on the mandrel of the forming tool and placed on the center of the lathe, the roller *B* was placed in the tool post as shown at *D*; the lathe tool *E* was then secured in the opposite tool post *E*, and the lathe was started up. The roller *B*, which is shown in position at *D*, would roll over the scollop on the forming tool *A*, and by so doing would feed the lathe tool into the work in the same manner. A very neat finish was done on the hand-wheels in this manner in less than half of the time it would take to file them to a finish.

Arrangement for turning scollop hand-wheels in a lathe.

Facing Off an Elbow

By Albert F. Bishop

THE mechanic at times has very awkward things to hold while machining—an elbow for instance. The elbow is first placed in the chuck as in Fig. 1. A 2-inch L would need a short piece of shafting about three-quarters of an inch in diameter, sawed to a bevel on one end to fit roughly the outside sweep of

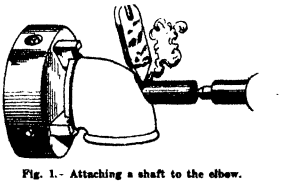


Fig. 1.- Attaching a shaft to the elbow.

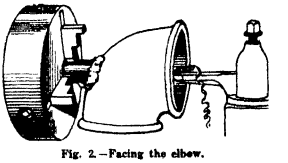

Fig. 2.—Facing the elbow.

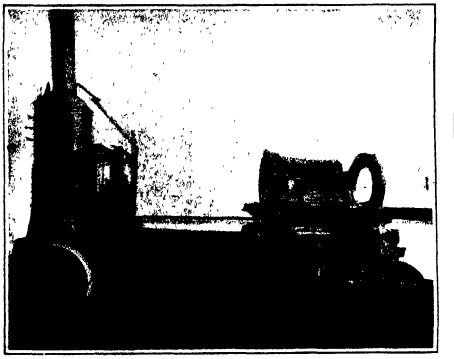
the elbow. The other end should have a center, which the tail center holds central while the beveled end is tacked with solder to the brass or malleable iron elbow. It is then removed from the chuck, and the soldering is completed. Fig. 2 shows the short piece of shafting placed in the chuck, which holds the elbow firmly enough to face the flange ends and bore out or cut a new thread if desired.

Workshop Notes

Soapstone for Babbitt Casting.—When casting babbitt in molds or pouring babbitt boxes, powdered soapstone dusted in the molds or aperture for receiving the babbitt will very much improve the flow of metal, and you are quite sure of getting a full box or perfect casting.—L. M.



Preparing Metal for Painting.—In preparing for painting iron or metal which is quite smooth, or has been machined, say, for instance, a cylinder head, take raw oil and moisten a cloth so that a very slight amount of oil can be rubbed over the surface of the machined iron. Be particular not to get on too much, as it should be thoroughly dried before the paint is applied. It will take several days or a week for it to dry sufficiently. This preparation keeps the paint from chipping.—A. F. B.

Machine for Treating Poles With Preservatives

IT is at, or near, the ground line that a pole is most subject to decay, for here it is exposed to the moisture of the ground and to the air as well and hence provides an excellent breeding place for destructive insect life. In order to preserve the pole against decay, it is unnecessary to treat more than a limited zone in the neighborhood of the ground line. Recently a machine has been perfected by which the pole may be thus economically and expeditiously impregnated with creosoted oil, or other preservatives. The oil is forced into the wood by means of air pressure. The machine, as shown in the accompanying illustrations, is provided with a boiler for generating steam with which the air compressor is operated, and with which steam coils are heated to warm the oil that is stored in a reservoir in the middle of the machine A pair of iron skids will be observed extending crosswise of the machine, and upon these the pole is supported. Two iron rings, shown in the illustration, may be opened to admit the pole, after which they are closed by operating a hand wheel. A spool, bearing a canvas band three feet wide, is then revolved by a hand wheel so as to wrap the cloth tightly about the pole. The edges of the band are reinforced to make a snug fit and they are subjected to air pressure, so that the band will form an airtight annular bag about the pole. This done, the heated oil is introduced into the bag through a pipe under a pressure of about five pounds to the inch It has been found under test that a 10-minute treatment is sufficient to force about a gallon of oil into the pole The oil is forced into the wood to an initial depth of three-sixteenths of an inch, but it continues to penetrate the wood after the pressure is relieved, and at the end of a few days reaches a depth of about one-half inch After the pole has been treated, the spool is revolved to unwrap the cloth band from the pole, the rings are opened and the pole is rolled off the opposite end of the skids A pan is located under the band to catch any oil that may drip from the cloth, or that might ooze out through checks in the wood during the treatment The machine shown in the illustration handles poles from seven to twenty-four inches in diameter

Machine for impregnating poles with creosote

Applying the preservation in a limited zone.

The Heany Tungsten Lamp Cases

ONE of the most interesting decisions in the history of the United States Patent Office has recently been handed down by Hon Cornelius C Billings, the First Assistant Commissioner, culminating a long and arduous series of hearings and examinations before him, the taking of testimony of many witnesses and the delivery of arguments by many noted counsel.

The investigation of the Heany applications was altogether unique so far as precedent in the Patent Office was concerned It was the direct outcome of the famous Heany criminal trial, in which John Allen Heany, Ned W. Barton and Henry E. Everding were tried for fraudulent manipulation of records in the Patent Office. The applications involved the alleged invention of tungsten filaments for incandescent lamps, and for the process of making filaments from metals in a colloidal form.

Certain charges made by Principal Examiner A. F Kinnan, of Division 37 of the Patent Office, were the basis of the investigation, concerning applications serial numbers 225,769, 332,786 and 344,-068, filed by John Allen Heany; of charges relating to the said Heany application No. 238,769, and its alleged divisional application No. 344,068, set forth in the petition of Hans Kuzel, who is involved with Heany in interference No. 27,073, and of charges concerning said Heany's application, No 238,769, and its alleged divisional application, No. 332,786, set forth in the petition of Kuzel, Just and Hanaman, and von Bolton, who are involved with Heany in interference No. 27,074.

It was charged that Everding, a patent attorney, and Barton, an assistant examiner, in the year 1906 removed from the parent Heany application, certain sheets of the original specification and substituted other sheets, containing matter not in the original specification, when filed in 1904, and the matter contained in these substituted pages, it was alleged, was compiled by Barton, from information gained through his position in the Patent Office. It was charged that Heany aided, abetted and connived at the acts of Everding and Barton in this fraudulent substitution.

It having been shown that Barton and Everding were guilty of fraud, and they having been punished therefor, Barton having confessed before the criminal trial, and Everding being convicted, and, although Heany himself was acquitted, the charges made in 1909 by Examiner Kinnan led to the institution of the very exhaustive investigation which has just been finished, and which occupied a period of about one year. The investigation had for its purpose to decide whether, in view of these substitutions and changes, valid patents could be granted, or whether the applications should be expunged from the files on the ground that they were fraudulent.

The taking of testimony was commenced before the First Assistant Commissioner of Patents on July 25th, 1910, all parties being represented, and was continued from time to time, and finally concluded April 21st, 1911 Respondents were given ample opportunity to cross-examine the witnesses produced in support of the charges and to rebut their testimony, and availed themselves of that opportunity Voluminous testimony was taken by both sides which was supplemented by stipulation into the record of certain testimony previously taken in the criminal trial

This proceeding grew out of a condition of affairs in the Patent Office which has occurred for the first time in its history So free from fraud or allegations of fraud has the Patent Office been, that no statute or rule of practice is found to cover specifically such a case The effort of the First Assistant Commissioner was to learn by due process of law, the truths surrounding the case and to render a judgment based upon those truths in accordance with the law.

Jurisdiction of the case was acquired by virtue of the general supervisory authority of the Commissioner of Patents over affairs in the Patent Office, its records and papers, which empowers him to grant valid patents upon legally effective applications therefor, or else to refuse to grant patents upon applications therefor, which are shown to have no foundation in law, and which patents, if granted, would, in his opinion, be null and void

The gravity of the charges preferred against the Heany applications by Examiner Kinnan, and the tremendous commercial value of the inventions involved, the control of which, upon the granting of patents would undoubtedly cause millions of dollars annually to accrue to the profit of the owners thereof, led to the absolute necessity for the discovery of priority of invention, and, if possible, to decide without a vestige of a doubt, which of the contending parties was entitled to status in the interference

In his decision in this proceeding, Mr Billings said

"It would be a travesty indeed, and against all legal principles to permit a party to an interference to remain a party thereto should it be found that the very applications of that party involved in the interference are fraudulent to such a degree that no valid patent could be granted based upon such applications or, in other words that any patent or patents granted upon such applications would be in valid and void on the ground of fraud A fraudulent application is in law no such application as to justify the grant of a patent thereon and the same is true when an application contains an incomplete and inoperative disclosure

During the progress of the investigation it was urged on behalf of the respondents that the question as to whether or not John Allen Heany was guilty of the fraudulent practices concerning his applications, was *res adjudicata* because of Heany's acquittal in the criminal court of the District

The Court of Appeals of the District of Columbia, which is the court of final resort in patent jurisdiction and is also the court which hears and determines appeals in patent cases from the decisions of the Commissioner of Patents, held that the power of the Commissioner to declare that the altered application is not "the application contemplated by the statutes as the foundation of the patent," was not barred by the adjudication in the criminal case," and said

"If he (the Commissioner) finds the alterations to have been made but without knowledge and consent of the applicant he will permit it to be corrected so as to restore it to its condition as originally filed

And also

If on the other hand he finds that it was tampered with by the connivance and approval of the applicant, he will probably enter an order refusing the application leaving the applicant his right to appeal therefrom

After fully and exhaustively considering the citations offered by the respondents, the First Assistant Commissioner held that the question of Heany's complicity in the frauds charged is *not res adjudicata* in the proceeding

Mr Billings touches briefly in his decision upon the introduction during the investigation of a mass of evidence by Heany, which was subsequently found to be manufactured under Heany's direction, for the purpose of proving that he (Heany) had invented a pure tungsten filament meandescent lamp prior to December 29th, 1904, the date of filing of his application, No 238,769, and to substantiate the contention that he had no motive whatever in perpetrating the frauds specified in the charges and admitted by respondents in their answers, to have been made in said application

During the investigation it was largely due to the efforts of the First Assistant Commissioner that the spurious nature of this so-called evidence was discovered, in which efforts he was greatly aided by the counsel for the respondents, who were unaware of the character of the evidence, and who demanded that the witnesses

whom they had presented should tell the entire truth no matter how damaging in effect it might be for their clients.

If, therefore, transpired that instead of showing that Heany could have no motive to perpetrate the frauds alleged, the evidence introduced on the contrary, shows that Heany did not have a conception of the uncertainties of the issues within the meaning of the patent law, prior to the filing of his application on December 29th, 1903, and that he did have a decided motive in attempting to obtain the benefit of that date for knowledge subsequently acquired.

The decision of the First Assistant Commissioner, therefore, in effect orders the dissolution of the interferences Nos 27,074 and 27,075, as to the party Heany, and directs that the amendment present to the parent application of Heany, No 2,48,769, filed December 29th, 1903, be refused entry and the application finally rejected, and a patent on that application finally refused on the ground that any patent granted thereon in view of the established facts would be held in the courts to be null and void and of no effect, on the ground of fraud.

The amendments presented in the "tungsten division" application, serial No 332,786, filed August 31st, 1906, are refused entry and the application is finally rejected and a patent thereon is finally refused, on the ground that any patent granted thereon in view of the established facts would be held in the courts to be null and void and of no effect, on the ground of fraud. Similar action is taken with regard to the "colloidal division" application, No 344,068, filed November 19th, 1906, and the amendment thereto.

The First Assistant Commissioner further ordered that upon the termination of the proceeding, each of the three Heany applications shall be endorsed with the words "Patent refused on the ground of fraud," and each of them shall hereafter be kept in the archives of the Patent Office, separate from the other applications for patent.

The inventions involved in the issues not only of the Heany applications, but in those of the interfering parties, are perhaps among those which claim the greatest public interest. The tungsten lamp, which is being universally adopted and which combines a higher efficiency with a lesser cost than the ordinary carbon filament incandescent lamps, is a possession the control of which is well worth the terrific legal struggle which has taken place both within and outside of the United States Patent Office.

Notes for Inventors

Some New Gayley Steel Process Patents.—James Gayley of New York city has secured a patent, No 1,002,576, for apparatus for drying air by refrigeration, and patents, No 1,002,577 and No 1,002,578, for methods of drying air, both of which include the refrigerating idea.

Short Claims in a Patent. Patent No 1,002,048, to Fred B Corey of Schenectady, N Y., assignor to General Electric Company, for a relay contact, is interesting because of the brevity of its claims. It has two claims, the first containing only six words and the second only seven words the second claim being identical with the first except for the addition of the word "malleable."

An Alarm for Cash Box of Pay Telephones.—In patent No 1,002,232, to William E Davison and Robert McAlpine of Detroit, Mich., is shown a telephone instrument and a cash box for the telephone and having a lock with an electric alarm which operates when the lock is unlocked or when the telephone instrument is detached.

A Cool "Bite" for Infants—Women with teething babies will be interested in a patent, No 1,002,364, to Josiah H Bridges, which shows a cooling receptacle and a hollow, imperforate mouthpiece whose interior communicates with that of the cooling receptacle so that the mouthpiece which the infant bites will be kept cool, and the receptacle has a non-conducting jacket which prevents the infants hands from coming in contact with the cold body portion

Women in the Patent Office Examining Corps.—One woman represents her sex on the examining corps of the Patent Office. For some years Mrs Noyes and Mrs. Lybrand were assistant examiners and became well known to most practitioners before they resigned their positions some years ago. Now the only woman on the force is Miss Marie K Saunders, a native of Missouri. She was assigned to the Patent Office August 3rd, 1901, as a copyist at a salary of $900 per annum, being appointed from Guthrie, Okla January 11th, 1907, after passing the rigid Civil Service examination for the position, she was appointed a fourth assistant examiner at $1,200 per annum, her salary being increased by operation of law on January 1st, 1908, to $1,500. On November 1st, 1909, she was promoted to be a third assistant examiner at an annual salary of $1,800 and still holds the position

Helping the Dentist.—A number of dentists have spoken to us about the desirability of an improved cement for certain classes of dental work, such, for instance, as setting inlays. It should be transparent, strongly adhesive, insoluble in the liquids of the mouth, quick setting, and be non-irritant to the pulp of the tooth. They also referred to the need of a gold preparation which can be worked with the same speed and facility and under the same conditions as the ordinary silver base alloys, or amalgam. Another thing desired by dentists is an abscess syringe, so constructed that it may be used in any position in the mouth for injecting fluid medicaments through the roots of teeth into abscess tracts. It should be so formed that the needle can be packed in position in the desired root with the barrel in such relation to the needle that pressure can be made in the barrel at a distance from the mouth and without force or strain upon the needle.

Ancient Inventors and their Secrecy—It is an interesting fact that the inventors of ancient times, while appreciating public patronage, described the uses and merits of their inventions instead of explaining the operations and principles thereof. In other words, while they enlarged upon the great things that could be accomplished by their inventions, they carefully concealed the means and modes of operation by which the results were to be accomplished. In the early days patents were often regarded as unrighteous monopolies and the patentees were held in great contempt. This prejudice would probably never have existed if patents had been confined to new inventions, but in those days exclusive grants were obtainable to control the manufacture and sale of the commonest articles in daily use. So objectionable did this practice become that the wrongful monopolies were held up to public ridicule and an old writer, Maitland, says in the "Antimasque of Projectors rode a fellow upon a little horse with a great hat in his mouth, and upon the man's head was a bit with headstall and reins fastened, and signified a projector who begged a patent that none in their kingdom might ride their horses but with such bits as they should buy of him. Then came another fellow with a bunch of carrots upon his head, and a capon upon his fist, describing (representing) a projector who begged the patent of monopoly as the first inventor of the art to feed capons with carrots and that none but himself should make use of that invention, and have the privilege for fourteen years, according to the statute."

Inventions Ahead of the Times—Frequently inventions are made before the time is ripe for them to go into general use. This is illustrated in the so-called fireless cooker which has recently come into popularity and is now used to a great extent. The fundamental idea of this cooker is not at all new, the apparatus in its main features being described in Ganot's physics as a Norwegian stove, no illustration, however, accompanying the description, at least in the edition we examined. Patents were also granted many years ago, both in the United States and England, for fireless cookers. In the English patent, No 778, of the year 1857, a Frenchman, Joseph Francois Marros of Paris, describes the invention as consisting in putting the food to be prepared for eating with water and suitable condiments, in a cooking vessel of the digester kind, which vessel is placed on the fire and the temperature is raised as high as two atmospheres or about 121 deg C, indicated by a suitable valve, fitted on the lid of the vessel. When the valve is raised and steam escapes, the vessel is taken from the fire and put in a double wrapper case which is packed with suitable insulating material, and the cooking keeps on until it is completed by the confined heat, sometimes five or six hours or more. In this form of cooker, the food is brought to a cooking heat in the vessel before the latter is placed in the insulating casing. In a United States patent, No. 59,441, of 1866, expired long since, the cooking vessel is placed in the insulating casing with a chamber around the vessel and in which chamber hot or boiling water is placed so the heat from the water will slowly cook or stew the meat or vegetables placed in the vessel. This old idea is somewhat similar to that pursued in some of the modern cookers in which radiators in the form of plates are heated and placed in the casing adjacent to the vessel containing the food to be cooked. Most of the earlier patented cookers describe the apparatus as adapted for use as a refrigerator as well as a cooker.

A Swinging Emery Wheel.—A very interesting and novel feature to be seen in a few of the most advanced machine shops is a swinging emery wheel. The wheel and the motor which drives it are mounted together and are suspended from the ceiling and the lower part of the wheel is exposed while the upper portion is shielded by a hood for the protection of the workman. The outfit is suspended by means of a bar, on one side of which is the motor which balances the emery wheel secured at the end of a four-foot shaft. The apparatus may be raised or lowered to any desired height to suit the character of the work, and as it is thus suspended, the operator manipulating the wheel by two arms extending from the hood, it is possible to move the wheel over an area of eight feet. This installation is designed principally for the purpose of finishing heavy pieces of work which cannot be readily moved back and forth over the stone. The connection between the motor and the wheel is direct, and as there are no belts or chains, this advantage is great. The device is intended to withstand hard usage. By this arrangement delays due to belt failure are entirely avoided.

A New Automobile Fire Engine.—The Springfield fire department has displaced a team of three horses, formerly attached to one of the water towers, and this piece of apparatus is now drawn to and from fires under power without any further alteration or change than the removal of the front wheels. For this purpose a "dreadnaught" was made use of which is a sturdy little motor, mounted on a truck, adapted to support the front end of the water tower, and equipped with a motor of sufficient power to draw it rapidly to the scene of action. In order to permit of its making very short turns and of winding through narrow thoroughfares, the front wheels of the tractor are mounted so close to each other that it has the appearance of a single large wheel.

Automatic Gas Cocks.—Although we frequently read of deaths from accidental gas suffocation, it is found that many patents, probably several hundred, have been granted for devices for automatically shutting off a gas cock if the gas be blown out or accidentally extinguished. An early, if not the first, patent for this subject is the patent, No 71,440, to Smith, issued February 11th, 1868, and long since expired.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Household Utilities.

CLOTHES DRYING FRAME.—J. W. Hoxsie, Chicago, Ill. This invention supplies a frame for use within the confines of a dwelling it is particularly arranged to elevate the drying frame and the articles suspended thereon from the floor, and if the room in which the frame is installed permits, above the heads of the occupants of the room to allow persons to pass beneath the frame and the clothes.

Electrical Devices.

INDUCTION COIL.—J McIntyre, Jersey City, N J. In this improvement the induction coils an adjustment of the contacts is obtained in an effective manner, according to the use to be made of the apparatus and relative to the existing strength of the source of electrical energy, the arrangement regarding the employment of the expensive platinum contacts exceedingly economical. It relates to electrical apparatus in Letters Patent of the U. S., twice granted to Mr McIntyre. He has also invented another induction coil, and it relates to electro-magnetic apparatus, its object being to provide certain improvements in the Ruhmkorff and other types, whereby a non rotatable contact is bodily moved with its bearing on the bridge or post, to bring this contact in proper relation to the opposing contact and to securely lock the movable contact and its bearing in the adjusted position against accidental movement

Of General Interest.

APPARATUS FOR PRODUCING VARIOUS SOUND EFFECTS FOR THEATRICAL AND LIKE PURPOSES.—A H Musgrave, Victoria Works, Bagley Street, Bradford, England. This invention relates to apparatus for producing various sound effects for theatrical and like purposes, the apparatus being particularly advantageous for use in combination with kinematographs and the like, for imitating the sounds that would be produced in the scenes that are being depicted. The details may be varied to suit particular requirements. It may be operated by one or more electric motors with switches or control handles for the different effects.

MAIL BOX AND CARRIER.—H A Schmitz, Dorchester, Wis. This invention has in view a box in which the mail is well protected from the weather and readily introduced and removed, and further and principally resides in the mounting of the box so that it is accessible to the carrier without leaving the road, and also accessible from the premises at a substantial distance from the road the box and its carrier offering no substantial obstruction to travel along the road, but adapted to swing from a position over hanging the road to a reversely extending position.

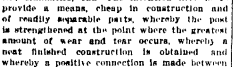
PEANUT ROASTER.—L. Roenkeraus, Rhinebeck, N Y. This invention pertains to roasters for peanuts and like products, and has reference more particularly to a device of this class, which comprises separable casing sections, a roaster removably mounted between the sections, and a burner under the roaster, the casing having a warmer therein above the roaster.

SHOEMAKER'S JACK.—F O Rollins, Newburyport Mass. In this case the improvement refers to shoemakers' jacks, and the object is to produce a jack having great durability, which will be adjustable so as to change the height at which the shoe is held, and also to enable the shoe to be held either at the right or at the left side.

FLASH LIGHT APPARATUS.—H J Paul and F Kuhn, New York, N Y. This invention refers more particularly to photographic and like apparatus which comprises a support, a frame carried thereby, an envelop supported by the frame, for confining the smoke and other products of combustion of the flash light material, and a slide mounted upon the support and connected with the envelop so that the last can easily adjust itself to the expansion due to the explosion.

TRAY.—C A Anderson, East Orange, N J. The front end of the tray extends upwardly at an obtuse angle relatively to the bottom of the tray to form an abutment which will normally retain slips of paper in the tray, while readily permitting the user to slip the uppermost slip of paper over the inclined front end of the tray by placing the thumb against the extension of said front end formed to retain a pencil, and his first finger on the uppermost slip of paper.

SOLDERING APPARATUS.—W. W. Farnsworth, Brushton, N Y. This invention refers to improvements in devices for soldering parts, especially parts of jewelry, optical goods, etc. It provides means by which two small parts may be held rigidly, while the soldering is conducted. It provides a small pad of heat insulating material, which may be held in the hand while parts to be soldered may be securely held upon the pad by devices which may be



easily manipulated to release or retain the parts to be mended

METHOD OF DISINFECTING BOOKS—I. H. Hoon, 113 Poplar St., Greenville, Miss. This method consists in spreading or opening the leaves of the book by a blast or current of air, and in simultaneously delivering to the spread or opened leaves a disinfecting substance by the same current of air. The books may, however, be treated in the same manner, separately or in lots, by passing the blast backward and forward over the books, and by reciprocating the books through the blast or current of air

FEED TROUGH.—W RANDALL, Los Angeles, Cal. The object in this instance is to provide a simple and inexpensive trough wherein but a small amount of food is exposed at once, and wherein as the exposed food is removed the supply is renewed. A constant supply of food is obtained Four kinds may be fed at once

FENCE POST.—J. E HUSSEN, 526 Hoffman St., Hammond, Ind. The intention here is to provide a means, cheap in construction and of readily separable parts, whereby the post is strengthened at the point where the greatest amount of wear and tear occurs, whereby a neat finished construction is obtained and whereby a positive connection is made between the wires and the post

TOBACCO SMOKING PIPE—SAMUEL E CRASSEY Alfred, Maine This invention provides a stem for a pipe pivotally connected to the bowl thereof to permit the swinging of the bowl to a position parallel with the stem, provides in the pipe a bifurcated extension for the stem to form a yoke for the bowl, and provides an automatic cover for the bowl operative when the same is disposed in housed

TOBACCO SMOKING PIPE

position The invention forms a double armed stem section having in one or both of the arms the necessary smoke channel, which unite to form a single channel for the mouth piece, and in pivotally connecting the arms and bowl It provides a convexed cover guidably mounted in structure of arms and spring actuated to normally extend into the path of the pipe bowl when swung to housed position The illustration presents a side view

COLLAPSIBLE CONTAINER—T. F. TASNEY 447 W 14th St., New York, N Y The invention pertains to a container of a type adapted to contain cigarettes or the like It can be made from less material and with less trouble than those now on the market The container can be collapsed as the articles are used so that a bulky package need not be carried about when the container has therein only one or two of the articles

MINIATURE GREENHOUSE—F W SCHWARZ, 492 S 3rd St Columbus, Ohio This device can be made in any size required and put into use in any garden or field The parts thereof are hinged to one another so that the whole structure can be taken down and stored away so as to occupy a minimum amount of storage room

Hardware and Tools.

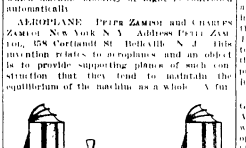
PIPE WRENCH—W L. BESSOLO, Box 522, Birmingham, Ala The invention consists of a handle upon which is mounted a jaw member so that it has a limited degree of rocking movement With this jaw member is pivotally connected a jointed member exteriorly toothed to interlock with a spring-actuated pawl also pivotally mounted on the shank member and upon the rocking jaw member When the last is moved in one direction the co-operating jaws are made to tightly grip the pipe interposed between them through means of the pawl, while when the rocking member is moved in opposite direction the space between the jaws allows the wrench to be turned on the pipe to get a new hold

MARKING TOOL.—J A WICKES, 64 Broadway, East Somerville, Mass. This invention provides a tool with marking faces having corresponding oppositely extended distinguishing features; provides in a marking tool a plurality of hammer heads bearing distinguishing marks identifying the character being printed, and provides for a tool for accurately and quickly distinguishing the correct position of the character imprinted

SHEAR GUIDE.—T H. SUZUKI 1031 Washington St., San Francisco, Cal The object here is to construct a device wherein a blade is held in adjustment against a sharpening stone in such a manner as to allow of a free swinging movement of the edge of the blade across the sharpening stone. The inclination of the blade on the stone may be varied at will, and held at its adjusted position Means are provided whereby the stone will always be kept in contact with the edge of the blade.

Machines and Mechanical Devices.

PULLEY AND BEARING THEREFOR—M H AVERY, Dover, N H This invention provides oiling devices for pulleys arranged for continuous circulation of oil from the center to the end of the bearing and return, provides a construction for pulleys whereby to avoided dropping of oil from the pulley or bearing therefor, and provides an oil distributing and lubricating bearing for a loose pulley



SUGAR BOWL.—I MATAS, Patterson N J The purpose here is to provide a bowl designed for use in restaurants, hotels and other places where sugar is placed at the disposal of patrons, and having mechanism inside the same to enable the sugar to be readily and easily discharged from the bowl into a glass or other, receptacle without necessitating the use of spoons

FLYING MACHINE PARACHUTE—J W DODSON, New York, N Y It is one of the objects of this invention to provide a parachute which will correspond to a lifeboat on a water vessel, and enable the aviator to detach himself safely from the aeroplane in case of accident to the latter The parachute may be extended and let out any distance from the aeroplane, so as to aid in supporting the same, if necessary, and to act as an air anchor

COPING MACHINE—J G BENSTER and H L. BENSTER, Moline, Ill This invention has reference to cutting and punching sheets and bats, and its object is the provision of a new and improved coping machine more especially designed for shaping the ends of I beams channel beams and other beams used in structural steel work, to insure close fitting of adjacent members at an angle of 90 degrees or less, as the case may be

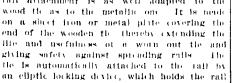
FLYING MACHINE—M G ADAMS, Parsons, Kan This invention more particularly relates to a machine in which a steering surface such as a rudder which is manually or otherwise operable is controlled by a further surface which is free to move under the influence of air pressure thereagainst The stability of flight of the machine is automatically controlled Mr Adams has invented another flying machine, in which is provided a steering surface or rudder, and a controlling surface operatively connected with the steering surface and arranged to move bodily under the influence of air pressure thereagainst and in which machine stability of flight is controlled automatically

AEROPLANE—PEIPE ZAMBINI and CHARLES ZAMBINI New York N Y Address PEIPE ZAMBINI, 358 Cortlandt St Belleville N J This invention relates to aeroplanes and an object is to provide supporting planes of such construction that they tend to maintain the equilibrium of the machine as a whole A fun-

AEROPLANE

ther object is to provide supporting planes and side planes so disposed toward one another that not only is the equilibrium maintained but each serves as a lifting or resistance element Means are provided for protecting the ends of the supporting planes in case they should dip downwardly and come in contact with an obstacle in its path The engraving shows a plan view

Prime Movers and Their Accessories.



STARTING DEVICE FOR INTERNAL COMBUSTION ENGINES—R O LE RASON Masonic Temple, Portsmouth, Ohio The object here is to provide means which may be used at will to connect an auxiliary gas tank with the intake of the engine, so that the gas will mix with the explosive mixture and flow into the engine cylinder, which with a proper speed mechanism will insure an explosion in the engine cylinder on the first or in any case on the second, rotation of the engine shaft

MEANS FOR COOLING INTERNAL COMBUSTION ENGINES—R F. E CHAVEZ Antigua, Guatemala In the present patent the object of the invention is the provision of a new and an improved means for cooling internal combustion engines in a more efficient economical manner, and for this particular purpose use is made of moistened air moved in contact with the cylinder of the engine

Railways and Their Accessories.

RAIL JOINT—F C BOYAMIGHT, Philadelphia, Pa This invention has reference more particularly to a rail joint which comprises a base having rail engaging means, a chair movably mounted upon the base and adapted to support the rail ends, means for causing the relative lateral movement of the base and the chair to secure the rail ends in position, and means for holding the rail ends.

METALLIC TIE AND RAIL FASTENING DEVICE—JOEL F. ROBINSON, Central, S C This device eliminates the use of spikes which split the tie, work loose, and otherwise destroy its life and causing many wrecks The rail attachment is as well adapted to the wood tie as to the metallic one It is made on a short iron or metal plate covering the end of the wooden tie, thereby extending the life and usefulness of a worn out tie and giving surety against spreading rails The tie is automatically attached to the rail by an elliptic locking device, which holds the rail

METALLIC TIE AND RAIL FASTENING DEVICE

immovably, guarantees an exact gage of track and is assable only in the use of a wrench The locking device is underneath the rail and inaccessible to train wreckers It is not liable to be disturbed by any cause until a wrench is used The form of tie is especially adapted to elevated wayides and on ballast roadbeds The invention provides for insulation, and the engraving shows a top plan view

CAR TRUCK—C A LEGGETT, Wayne Maine The object here is to provide trucks for railroad cars constructed and arranged to dispose the axles of the wheels in a radial position upon the curved sections of the track in order to eliminate friction at these curves A further object is to so arrange the trucks that any obstruction upon the track would not tend to cause the wheels to leave the roadbed

DOOR FOR GRAIN CARS—I W WHITTIER Palmyra, Neb This invention relates to a door for grain cars coal cars and the like One object of the improvement is to provide a door which can be readily and easily fastened to the framework when in use and may readily be swung out of the way when not in use, and further provides means for attaching the door to the framework on the car in both of these positions

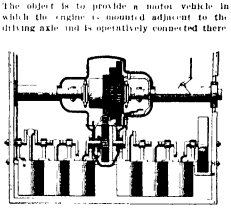
WATER GAGE—J A COOPER Jersey City and W R VAN BUSKIRK, Patterson N J This invention provides a water gage for determining the level in boilers especially on locomotives The gage is strong and durable and is not liable to blow out and even if it should blow out the fragments of glass would be caught by a protector, preventing them from flying and in injuring the person or eyes of the engineer

DOOR HANGER FOR CAR DOORS—J T GRIMSHAW and L. E WILLINGTON Rialto Cal An object in this instance is to provide a hanger which will permit the car door to be easily opened and closed and which will make the binding of the door impossible A further object is to provide a device having a novel form of adjustment for the same purpose, whereby closing the door together with means for preventing wear of the attachments

Pertaining to Recreation.

SWING.—G D TUCKER Markham, Miss An object of this invention is to provide a support for a swing rotatably supported on suitable rollers with means for holding one or more of said rollers by the swinging action of the swing so that the device as a whole will move over the ground and if desired above a common pivotal point

GAME APPARATUS.—I E YOST care Yost Yost Co Arkansas City, Kan An object of this invention is the provision of a new and improved game apparatus for playing a game of checkers on a map in the use of traffic tools or the like more or less as done by the couple as points to move to and towns at the end of the map a King for The game is likewise interesting and educates in geography

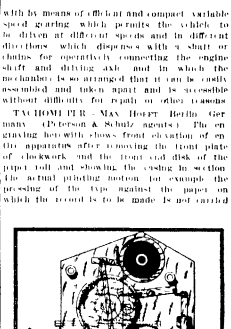


Pertaining to Vehicles.

PNEUMATIC WHEEL.—S P COX Bergen N Y This inventor provides an improved construction of wheel in which the tire is made up of separate units each carrying its own pneumatic cushion and the individual tube for each associated with the cushion the various units being removable at will and consequently interchangeable

BRAKE LOCK.—W S HARRIOT Anthony Ind. To accomplish the purpose of this invention use is made of a brake lever for connection with a brake shoe, a locking tool mounted on the brake lever, a locking lever adapted to be engaged by the locking tool to lock the brake lever relatively to the locking lever and means for limiting the movement of the locking lever

VEHICLE WHEEL.—J C THOMS, Burke Idaho The aim in this case is to provide a novel construction of spring wheel which will have sufficient resilience to permit its practical operation on automobiles and the like without pneumatic tires An important feature of the invention is the coiled portions of the spokes which give greater resiliency to the spokes and thus improve the action of the wheel



GEARING.—HOWARD G CARR, 910 E Main St Hoopeston, Ill This invention is shown in the enlarged plan view of the chassis of a motor vehicle exhibiting the engine for driving the vehicle and in cross section, the gearing connecting the engine and the driving axle The object is to provide a motor vehicle in which the engine is mounted adjacent to the driving axle and is operatively connected there

GEARING

with by means of efficient and compact variable speed gearing which permits the vehicle to be driven at different speeds and in different directions which dispenses with a shaft or chains for operatively connecting the engine shaft and driving axle and in which the mechanism is so arranged that it can be easily assembled and taken apart and is accessible without difficulty for repair or other reasons

TACHOMETER—MAX HOERT Berlin Germany (Peterson & Schulz agents) The engraving here with shows front elevation of one the apparatus after removing the front plate of clockwork and the front end disk of the paper roll and showing the casing in section The actual printing motion for stamping the pressing of the type against the paper on which the record is to be made is not carried

TACHOMETER

out by a clockwork spring or weight adapted to be wound up periodically but either by coupling the printing mechanism with a shaft or some other part driven by the motor or by force of the person moving some operative part of the vehicle or motor Printing is thus effected with the great accuracy and the apparatus can not fail owing to insufficient force being an eliable as is occur when a clockwork spring is used The complicated mechanism heretofore necessary in order to automatically wind up a clockwork spring is now avoided

DOOR SIGNAL.—L L. BOGUS San Francisco Cal The object of the present invention is mainly to provide an automatically acting indicator device actuated by the closing of the door This device is particularly adapted for use on automobiles and other vehicles and at all times to see that the door is opened or closed without turning his head

SLEIGHING ATTACHMENT FOR CARRIAGES—I P MCCRACKEN Berlin N H This attachment is for use for baby carriages go cart and vehicles in general and it comprises a plurality of runners which can be suitably supported beneath the body of the vehicle and adjustably attached thereto so that they can be in inferior clear of the ground when they are not needed for use or lowered when desired to support the weight of the vehicle thereon

Designs.

DESIGN FOR A TEAPOT COFFEE POT, OR SIMILAR ARTICLE—M WEINTRAUB New York N Y This ornamental design for a teapot coffee pot or similar article represents a teapot of harmonious proportions and highly elaborate ornamentation Scroll work profusely covers the entire article except the numerous scenes of pastoral and social life pictured around the lower part

DESIGN FOR A SWIMMING BAG.—A P RASMUSSEN New York, N Y The view of a swimming bag of ornamental design shows an article of square form at the lower half Half way up the sides the bag is shaped with two graceful inclines the top one on each side forming the bottom of a ring the form two of which constitute the top of the bag

---

NOTE Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each Please state the name of the patentee title of the invention, and date of this paper

Notes and Queries.

Readily know your queries on separate sheets of paper when communicating about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your queries, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full names for correspondents are preferred from time to time and will be mailed on request.

(12556) J F S asks. *B* is a brass cylinder 2 inches diameter and 12 inches long. *A* is a plunger, weighing ¾ pound. *D* is a ½ inch pipe connected at bottom of cylinder *B* leading to tank 4 inches above top of cylinder. Why won't plunger *C* lift water or force it rather into box as the plunger is much heavier than the water it has to raise? What size pipe will it require, as I cannot increase weight of plunger? A. The true height of lift in your sketch is not 4 inches, but the total height from base of plunger when it rests on water to level of bend in pipe. A ¾ pound plunger in a cylinder of 3.14 inches area (equal to 2 inches diameter) will

balance a head equal to ¾ ÷ 3.14 pounds or 0.24 pound per square inch nearly, equivalent to 6.6 inches of water (since 12 inches head of water is 0.434 pound per square inch pressure). From your sketch we judge your plunger is about 6 inches long, and that the head of water is therefore about 6.6 inches at the height to which it is shown as rising while you would have to add ½ pound more weight to the plunger to lift it to the tank (disregarding friction). You can reduce the diameter of cylinder and plunger to 1.6 inches nearly, and the head will then just balance the ¾ pound plunger.

(12556) J M K asks. 1 How much loss of power would result in transforming say 10 volts, 10 amperes, direct current into 20 volts 5 amperes? Have you got a SUPPLEMENT describing such a transformer, and the making of same? A A large loss would take place in changing 10 amperes at 10 volts direct current to 20 volts and 5 amperes changed to 5 amperes at 20 volts. There is no transformer for a direct current excepting some form of an induction coil which will need an interrupted current. It would not be cheaper and simpler to double the battery and so get your 20 volts and 5 amperes by a suitable resistance. 2 Have you got a SUPPLEMENT describing a small voltmeter? Also a small ammeter. A You will find a volt meter and ammeter described in our SUPPLEMENTS 1215, price ten cents. They are of simple construction and can be made by an amateur. 3 Have heard that the Mississippi River flows up hill, being driven onward by the centrifugal force of the earth? A The expression that the Mississippi River flows up hill because of centrifugal force is not a correct expression. Water cannot flow up hill. A water level is the surface of still water anywhere on the earth. The ocean is level, but at the equator the water and the land surface are thirteen miles farther from the center of the earth than at the poles. The Mississippi River at its source is above the level of its mouth, and the water flows down to its mouth from its source. Centrifugal force lifts the water level thirteen miles at the equator above its position at the poles. A ship does not sail up hill from New York to the equator. It goes over a water level and neither up nor down.

(12557) J M says: Kindly let me know whether the wheels of an automobile on the inside or outside of a curve leave the ground when going at a fair speed around said curve, and why? A The inner wheels of a vehicle leave the ground first when it overturns in rounding a corner too rapidly. Centrifugal force acts outward upon the vehicle through its center of gravity, which is above the ground. The following is on the ground through the rim of the wheels. This forces the vehicle to turn over upon the outer wheels. The outer rail of a track is raised to prevent the same effect in railroad trains. The outside of a race track is banked for the same purpose in bicycle races. The riders lean in very far in rounding the curves to prevent being thrown outward.

NEW BOOKS, ETC.

A SHORTER COURSE IN WOODWORKING. A Practical Manual for Home and School. By Charles G. Wheeler. New York: G. P. Putnam's Sons. 1911. 8vo.; 386 pp., 765 illustrations.

Manual training is so recent an addition to the general curriculum that its exponents are apt to be either professional teachers whose knowledge of the subject, as regards practical or skilled mechanics whose ideas of teaching are somewhat crude. This "Shorter Course" is intended to help both classes, and the independent student as well. Its first division, "Common Tools and Their Uses," is very exhaustive and clear, being so profusely illustrated that the figures are often some pages in advance of the text which refers to them. The second part "Operations in Shaping, Fitting, and Finishing," tells how to miter, dowel, splice, cleat, chamfer, and groove. This division also gives instructions for moldings, for panel and door making, and for the elementary operations in simple carved work. An appendix deals with such primary principles of construction as are embodied in gates, simple bridges, and roofs; and with practical problems in drawing and in laying out work. In every way the manual excellently fulfills the purposes with which it set out, and is a worthy follower of the same author's "Wood-Working for Beginners."

GARAGES, COUNTRY AND SUBURBAN. New York: The American Architect, 1911. 410., 80 illustrations.

He must be hard to please whose eye is not gratified by the garages shown in the beautiful half-tone reproductions of this album. Even Cairo, Egypt, has yielded the publishers an artistic and satisfying model, while America has apparently been ransacked for buildings that delight the artistic sense and meet the most exacting practical requirements. The plans of most of these are included, so that much help is afforded the man who is deciding on the structural features of a new garage. Some twenty preliminary pages of text take under consideration the essentials of construction and equipment, including the safe handling and storage of oils.

THE LANDSCAPE GARDENING BOOK. By Grace Tabor. Philadelphia: The John C. Winston Company, 1911. 8vo., 180 pp., illustrated. Price, $2 net.

Gardens do not happen, declares Miss Tabor. A perfectly satisfying garden is the outgrowth of artistic sense, careful planning and accurate execution. In the large plans of her attractive volume are presented not only perfect vistas but also scenes which fall just short of the effect aimed at, by reason of some too insistent feature or some subtle lack. Without dwelling at great length on the cultural side of the matter Miss Tabor treats of the gardens of suburban home of moderate size in relation to its setting giving the laws that govern the arrangement of gardens, trees, shrubs and flowers as affected by the site and the house itself. In a word she talks about color in the whole difficult problem of making a house seem at home in its site. The utilization of natural features, the approaches, the blending of architecture and nature, making the most of views, the garden furniture and accessories—all these phases of the subject are capably handled. The illustrations are fine half-tone plates of representative gardens and houses interspersed with practical diagrams and planting plans.

THE ICE AGE IN NORTH AMERICA And Its Bearings upon the Antiquity of Man. By G. Frederick Wright, D.D., LL.D., F.G.S.A. Oberlin, Ohio: Bibliotheca Sacra Company, 1911. 8vo., 763 pp., illustrated. Price, $5.25.

The first edition of this work was published twenty years ago but the interesting manner in which it is written, combined with the width and accuracy of its observations and the value of its deductions, made it a popular and standard book. Much material has been added to include the later discoveries, together with fifty new maps and illustrations. There are several chapters on glaciers other than those of North America and the first part of the volume comprises an exhaustive study of ice and its action. The second part discusses the time during which the ice sheet existed, and the have upon man's antiquity. As the author of "Scientific Confirmations of Old Testament History," Dr. Wright naturally leans toward an interpretation of Nature which conforms to Biblical statement, and it is his contention that recent discoveries have in no wise falsified his original reasoning and theories, but that, on the contrary they show the date of the last glacial epoch to be more recent than that it is usually represented to be. There is a bibliography covering no less than thirty pages.

THE HOUSE FLY Disease Carrier An Account of its Dangerous Activities and of the Means of Destroying It. By L. O. Howard, Ph.D. New York: Frederick A. Stokes Company, 1911. 8vo.; 312 pp., illustrated. Price, $1.50 net.

Here is a timely work on a subject intimately touching the public health and welfare. The recent increased agitation against house flies and the danger they represent is proved to be a sane warning against a very real menace. The author gives a life history of the fly and, assisted by well-executed plates that show its organism and habits, cites exact experiments in proof of its activities as a disease carrier. The array of evidence is conclusive, and most interestingly presented. The reader is then enlightened as to remedies and preventive measures. These include the prevention of breeding by treatment of all places in which breeding is possible, keeping flies out of the house, and killing them as they enter. Some ten millions of dollars are expended each year in the United States alone in an attempt to screen dwellings against the entrance of flies and mosquitoes. Another not inconsiderable item of expense is incurred in trapping and killing the pests after an entrance has been effected. With a little harmonious action on the part of individuals, Boards of Health, and communities, the breeding places might be rendered harmless and these expenses avoided. Until this comes about, however, housewives may read in the latter part of the volume of almost every device ever thought of for disposing of the mature fly. As Chief of the United States Bureau of Entomology, Mr. Howard's utterances should carry authority and inspire confidence.

WESTERHAM WITH ITS SURROUNDINGS. A Handbook to Wolfe-Land. By Gibson Thompson. New York: Frederick Warne & Co. 112 pp.; illustrated.

The quiet little Kentish village of Westerham is the birthplace of General Wolfe. Although so near London, the surrounding district is intersected by rambling paths that give glimpses of some enchanting views. The village itself is little altered since the days of Wolfe. The philology of the name carries us back to centuries in the Domesday Book of William the Conqueror it appears as "Oistreham." The handbook—one of the famous "Homeland" series—while serving as a brief history and general guide to the district, lays much stress upon Wolfe's connection with Westerham, sketches his boyhood and manhood, and presents pictures of the vicarage in which he was born and of the buildings and byways so familiar to him.

PRELIMINARY REPORT ON A VISIT TO THE NAVAHO NATIONAL MONUMENT, ARIZONA. By Jesse Walter Fewkes. Washington: Government Printing Office, 1911. 8vo.; 35 pp., illustrated.

This Bulletin 50 of the Bureau of American Ethnology, is a most instructive monograph on the important prehistoric ruins reserved under the name Navaho National Monument. These ruins are connected with Hopi pueblos still in hand, in which are preserved traditions relating to them and their ancient inhabitants. The Preliminary Report will be followed later by a more detailed account based upon a thorough and extended examination. In the meantime we have here much material for study and some admirable photographic reproductions of the major and minor treasures already revealed. There are maps of the groupings and sketches showing the detail of construction, with a map showing the surrounding country and indicating the location of the various objects of interest.

ADVENTURES IN HOME-MAKING. By Robert and Elizabeth Shackleton. New York: John Lane & Co., 1911. 12mo., 360 pp. Price, $1.75, postage, 10 cents extra.

There is always a demand for a book which deals with the transformation of an old house into a modern dwelling. The potentialities which exist in old houses, especially old colonial houses, is very great, and the authors of this book have performed a difficult task in an admirable manner. The finding of the house is discussed; this is followed by the planning, which begins with the library, then the fireplace and the secret stair are taken up; then the old parlors are dwelt upon, and this is followed by a description of the whitepanelled dining room, the halls, the bed rooms, the guest room, and then we are taken to the outside, where a formal garden, the lawn, the shrubs, the trees, the spring house, and the stone walled pool are all discussed. The illustrations, which are inserted apart, are excellent. There is little question but that the book will be warmly received.

THE MANUAL OF STATISTICS Stock Exchange Hand-Book 1911. New York: The Manual of Statistics Company. 8vo., 1092 pp. Price, $5.

It is hardly necessary to commend the thirty-third annual issue of this hand-book to those who are familiar with earlier editions. For the benefit of such investors as may not have seen the work we may say that it is a compilation of information about railroad, industrial, and government enterprises including all those of the United States, Canada, and Mexico whose securities are listed in the leading stock markets. Following the style of each corporation is the date of its formation and a brief history of its life to date, with a statement of its stock authorized and issued, its holdings, its bonded debt, and its floating debt. In the case of railroads even freight traffic statistics are given, and in all cases much detail as to dividends, surplus, and depreciation is added. Other features of the manual are tables of securities showing the high and low quotations of the past three years, and statistics on mining, cotton, produce, money, and banks. This reference book should be upon the desk of every investor, broker, and man of business.

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

BUSINESS OPPORTUNITIES.

I UNDERTAKE the placing and give all information concerning the purchase and sale of patents, formulas, oil products, mining, etc., in Canada. I seek also representation of good firms for Italy and Canada. Address H. Ingimbi, Rome-Caucasian Nephtha Company, Baku, Bali Gericht, Russia.

We represent "Wigsbee Square," a city residential part in Los Angeles City, on fine level type, and we want bids, suggestions and samples of the "real word" in sandmix system to carry out scenic lighting views and cashier for telephones, domestic and street lighting—maximum 30 houses, and complete universal street lighting system for 8 miles of streets, minimum conduit 3 miles. R. A. Rowan & Co., H. W. Hellman Building, Los Angeles, California.

BOOKS.

GET WISE—$4.00 BUYS SEVERANCE'S GREAT work on Rapid Methods in Shorthand and Written Arithmetic. 50 pages size 6x9½. Sent prepaid on receipt of price. D. N. Severance, Detroit, Mich.

FOR SALE.

FOR SALE—A Patent Curtain Hanger or Holder where no pins, hooks or rings are needed. Full particulars and terms on request. J. Krajkowski, 605 East Thompson Street, Philadelphia, Pa.

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our comprehensive plan by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your locality to step into a big permanent business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres., The National Co-Operative Real Estate Company, L 208 Marden Building, Washington, D. C.

PATENTS FOR SALE

FOR SALE—Patent No 989,418. Sprayer-proof sash lock. A fortune can be made from this invention. Price very moderate. No reasonable offer refused. Address L. H. Grau, 3501 Pine Street, San Francisco, Cal.

WANTED.

MUNN & CO.—Desires to secure the services of a competent mechanical draftsman who has had experience of patent specifications. Address Munn & Co., Patent Attorneys, 361 Broadway, New York City.

MISCELLANEOUS.

MOTORCYCLES CHEAP.—Send to-day for free catalog of new and used motorcycles. Also motorcycle sundries and attachable motor outfits for ordinary bicycles into motorcycles. Shaw Manufacturing Company, Dept. N, Galesburg, Kans.

GROWING Raising is the surest way to make Big Money on Little Capital. One acre will yield 800 lbs. Sells at 50 c lb. We will buy all you raise. Grow any where. Requires four years time only. If you are not satisfied with our proposition we will pay you for your time. T. H. Sutton, 80 Sherwood Ave., Louisville, Ky.

MAKE BIG MONEY operating a Detroit Post Card Machine. Prints postal cards made and delivered on the spot in ten minutes in the open street. No dark room necessary. It does the work of an experienced photographer to make first-class pictures. Pays a gross profit of 200 per cent. Write to-day for free booklet and catalogue. Detroit Specialty Co., Dept. F-V, St. Louis.

FREE—LIST OF PATENTS FOR PROFIT" Magazine. Send one four cent stamp and I will mail you this magazine absolutely free. Before you invest a dollar anywhere—get this magazine. It tells you how to secure by one dollar, how to invest $10 or more, and how to make from $100 to $1,000 per month. It tells how to judge different classes of investments; the real meaning of "Par Value," "Shares," "Dividends," etc. Send stamp now if you write to-day. E. L. Barber, Publisher, 425 S. 4th Av., Jackson Block, Chicago.

INQUIRY COLUMN

Inquiry No. 9965.—Wanted, to buy a patent nozzle, a ball-bearing axle, which could be purchased on a royalty basis; it must be clean and fully proved.

Inquiry No. 9966.—Wanted addresses of parties having Freshkeep faucets, if able to ship one.

Inquiry No. 9967.—Wanted addresses of firms making good-sized water turbines.

Inquiry No. 9968.—Wanted addresses of parties having a good-sized saw mill in any part of the world, which they would like to exchange for a farm in Ohio for removing the timber.

Inquiry No. 9969.—Wanted addresses of parties able to ship screenings, bran, shorts or any material suitable as an abrasive.

e Aeroplane in Naval Service

(Concluded from page 394)

deck of this boat and returns to it. rises obliquely or in spirals above its ating nest, and having reached a varia- e height, according to the lucidity of e atmosphere, it can, on a clear day, iscover the presence of the enemy on horizon a hundred miles in diameter, while itself remaining invisible and unassailable. Then it can redescend upon its ship and, by means of wireless telegraphy, send the results of its observation to the friendly fleet a couple of hundred miles in the rear. Thus, ten hours before coming in contact with the enemy, the commanding admiral would know of the presence, the strength, and the position of his opponent, and would be able to evade or attack, to join another division of the fleet, or to commence a flanking movement, etc.

At present we make use of wireless telegraphy alone. One or several scouts are sent ahead of the squadron. When they discover the enemy they are at close quarters, and even so they have a pretty poor view, they see from below, with a visual ray which grazes the sea and loses the relief, and at the same time it is necessary that they inform the commander-in-chief as soon as possible, the wireless is set to work, but it speaks without having seen or having seen but imperfectly. The aeroplane, on the contrary, takes its survey overhead, undisturbed, and out of harm's way It is the indispensable auxiliary of the wireless; it is the eye of the scout, as the radio-telegraph is his mouthpiece, the two elements complement each other, they are inseparable.

But I insist on this point, that for its present use, as yet the aeroplane of the high seas be considered only as a "giant aerial periscope"; i. e., it must not go far from its point of support, it must not get out of sight of it, so that if any vexatious motor troubles occur, the convoy may immediately hasten to the succor of the poor shipwrecked bird

For our flying machine is not yet acclimated to extended maritime excursions, and over sea as over land the stoppage of the motor may happen suddenly On land this accident is of minor importance; a landing is made with more or less difficulty, but the landing is made; the injury is repaired, and you depart once more

But at sea the aeroplane which descends to the water because of motor trouble, even if provided with floats, is very probably not in a position to be repaired by the pilot The aviator cannot leave his seat to change a spark plug or mend a feed-pipe. He cannot get off again by himself, at least with the present motors.*

We have to-day flying machines, which fly as well over water as over land, if not better Let us make use of them at once, such as they are, that is the most urgent point, and afterward we can apply ourselves to the long and arduous task of making them veritable sea birds, with untiring wings, masters of wind and wave.

And so this end what is necessary? No great thing to begin with, and above all not many operators'—a few aviators with sufficient knowledge of the technique of aviation, a few carpenters and mechanicians, a much greater number of machines, naturally, than there are pilots, a repair shop, and a judiciously chosen aviation field on the seacoast in a favorable climate. Then, on the sea, a specially equipped cruiser, two torpedo boats, or better, two motor-boat scouts, and a tug.

Maritime aviation exists already in latent fashion; to co-ordinate its elements and to know how to set them in motion would be sufficient to endow the marine with this new service which might be to it of so much assistance.

* This can now be accomplished, thanks to a device recently on the "Comet" of Voisin, by which the pilot himself can start the motor without leaving his seat.—Ed.

Indoor Lighting, Natural and Artificial

(Concluded from page 393)

that no light shall fall directly downward, and its glass sides shall be at such an angle as to deflect the entering light as much as possible away from the vertical and all of the glass surfaces should be of a quality of glass that will cause a diffusion of the light

To make it impossible for the sun's rays to fall directly on the floor, and to direct the light toward the walls, the superstructure must have the form of a large prism, the top being entirely opaque and the sides sloping at an angle of 30 degrees. With this construction the light is admitted only through the sloping sides, it is partially diffused and its principal forces is directed toward the gallery walls The under skylight or ceiling glass gives a further diffusion and if the quality is correctly selected, it will thus practically obscure the source of light from the observer's eye and if the color of the floor is made darker than that of the walls, the result is very satisfactory and the true requirements are met without the introduction of a canopy or other objectionable screen, at least so far as daylight lighting is concerned

The artificial illumination equipment must necessarily be of a design that gives full consideration to the fundamental principles observed in connection with daylight lighting

Owing to our ability to direct and regulate the force of the light more readily under artificial conditions, we can, with this form produce results even more perfect with respect to diffusion and uniform wall intensity, than are possible under daylight illumination; and though perhaps not exactly reproduced, the quality and color of the daylight can be approximated closely

For many reasons the electric lamp is the most suitable for interior lighting A type, however, must be selected that will give a steady light and the electric wiring must be so planned as not to interfere with this condition As in the case of the power of a water fall, the energy of light, if under control and suitably applied, will accomplish much, but if incorrectly used, its efforts may do more harm than good

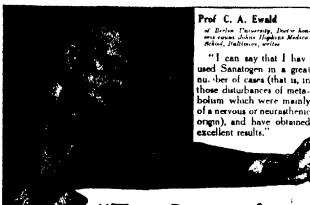

Fig 3 is an illustration of this latter condition, from which it will be seen that two brilliant electric lamps have been placed between the observer's eye and the objects which it was intended should be lighted

Another mistake frequently made in lighting pictures, or other similar exhibits, is to use an electric lamp in a trough reflector, the whole device being placed in front of one or more pictures the idea being that a strong light is thus cast, and the source of light is screened from the observer's eye, all of which is true, but the effect is a very "spotted" picture. The best results from artificial lighting will be obtained when the light sources are entirely outside of the room in which the exhibits are displayed

Figs. 1 and 2 illustrate galleries of equal size where the artificial lighting has been so arranged and where the prism-shaped superstructure has been used to provide the best natural lighting The photograph from which Fig. 2 is reproduced was taken by daylight only with a three-minute exposure, and it is clear from the reproduction that the principles governing the best interior lighting have been well carried out in this installation

The prism superstructure also serves another excellent purpose, for it provides a housing in which the simplest, but most effective artificial lighting equipment can be arranged Within this space, specially constructed electric fixtures should be hung, the lamps being supported in rows, and at a uniform distance from the under glass The fixtures themselves will thus be entirely screened, as the glass, when properly selected, will diffuse the entering light and practically nothing can be distinguished through this glass from below. The fixtures themselves being entirely screened can be made of the simplest pipe construction, thus involving a minimum of cost.

By placing a concentrating type of opaque mirror reflector just back of each of the incandescent lamps and adjusting these lighting units at a pre-determined angle, numerous beams of light will be thrown directly on the walls of the room below, and by properly calculating the location of the lamps and their number, and by giving the inner surface of the mirror reflector a double angle, thus making its sectional form approach the

Prof C. A. Ewald of Berlin University, Doctor honoris causa Johns Hopkins Medical School, Baltimore, writes

"I can say that I have used Sanatogen in a great number of cases (that is, in those disturbances of metabolism which were mainly of a nervous or neurasthenic origin), and have obtained excellent results."

Emperor of Austria's Private Physician

Surgeon - General Dr. Karel of Vienna

I have been using Sanatogen with splendid results and recommend it continually and everywhere because I am thoroughly convinced that it is an excellent food-tonic

Sir Gilbert Parker, M P

the eminent novelist and politician London writes from

"Sanatogen is, to my mind a true food-tonic, feeding the nerves, increasing the energy, and giving fresh vigor to the overworked body and mind."

Hon Shelby M. Cullom

U S Senator from Illinois, writes

"I can state that I have been decidedly benefited by the use of your Sanatogen I consider this preparation very valuable as a reconstructive of the nervous system"

Hon. Miles Poindexter

U S Senator from Washington writes

"I am sure Sanatogen has benefited me greatly A few weeks use of it has produced better digestion, better sleep, and a feeling of greater strength"

"Those Praises of Sanatogen Set Me Thinking"

There *is* a thought-stimulating power in the earnest words of famous men and women who testify to the benefit they have received from the world's greatest food-tonic.

They will set *you* thinking—they will remind *you* that nature has set limits to your endurance, and that when you have drawn too heavily upon your mental and bodily resources you must *make good the loss.*

You cannot *borrow* continually from your strength account—you must *pay back*, and Sanatogen is the direct, natural and consistent means of *restoring* to jaded nerves and exhausted tissues the losses they have endured.

Sanatogen the food-tonic is scientifically prepared to do this very thing Its splendidly combined body elements give it a natural, constructive, assimilative force in reaching weakness and in imparting strength

Sanatogen is a *rebuilder* In place of the dangerous stimulation of a drug, it supplies a steady *food-force* that nourishes and gladdens the system Fifteen thousand practising physicians bear written testimony to this unique and vital quality in Sanatogen.

—Nothing will "set you thinking" like Sanatogen itself!

We ask you earnestly to get acquainted with Sanatogen Investigate our claims first if you like, and we are only too glad to have you do so Ask your doctor about it, and in any case write at once for our book, Our Nerves of Tomorrow," written in an absorbingly interesting style, beautifully illustrated and containing facts and information of vital interest to you This book also contains evidence of the value of Sanatogen which is as remarkable as it is conclusive

Sanatogen is sold in three sizes, $1.00, $1 90, $3.60

Get Sanatogen from your druggist, if not obtainable from him, send us his name and address, and upon receipt of price,

THE BEST LIGHT

line of the true parabola, we will obtain the greatest benefit from each unit of illumination provided.

The photograph from which Fig. 1 is reproduced was taken entirely by the artificial light provided by an overhead electric lighting equipment of this kind, and it is interesting to note that while the exposure in this instance was the same as that of Fig. 2 (three minutes) the diffusion of the light, in the case of Fig. 1 is superior to that obtained from Nature's lighting and the relative intensities of illumination of the interior surfaces of the room in Fig. 1 more nearly accord with perfect conditions, the intensity on the wall surface being almost exactly uniform throughout.

This latter result is accomplished in a very interesting way, for as stated before, the force of the light from the incandescent lamps is thrown directly on the walls, but the beams of light are so adjusted that the fringe of one overlaps that of the next all of which in turn are diffused as they pass through the ceiling glass. An observer standing underneath the ceiling glass, looking upward, can scarcely detect the position of the sources of the light, so nearly are they screened by the underside of the opaque reflectors.

A comparison of Figs. 1, 2, and 3 brings out clearly the importance of eliminating the source of light from the field of vision and the need for a uniform intensity of illumination on the wall surfaces also, the fact that artificial illuminating equipment can be planned for interior lighting that will produce results very closely approximating the best to be had under natural lighting conditions. This application of illumination might suitably be termed directed-indirect lighting and its field is almost unlimited for interior use.

A Landsman's Log Aboard the Battleship "North Dakota"—II

(Continued from page 891)

Phillip, whose "Don't cheer, boys, the poor fellows are dying" as it rang down from the bridge when the "Texas" drew up to one of the sunken Spanish cruisers after the Santiago fight, was one of the finest expressions of the spirit of the navy that ever became a classic. Times have changed since then, and people too. Certainly the navy has changed, and in nothing so greatly as in its gunnery. I crawled around the ship looking for broken metal, whose white fractures would show that they were recent and had been made by the "Delaware" in that day's firing. There they were—holes near the channel plate, where the shots had entered, and right holes near the water line on the lee side of the ship, where they had left it. There must have been others—I had no time to look for them. Indeed, I was perfectly satisfied to find this much evidence that projectiles fired at these unprecedented ranges had struck the diminutive mark afforded by this little ship. Whose starboard lee sunken condition was not more than ten or twelve feet. The "Delaware," in hitting the "San Marcos" at eight to ten mile ranges, had done incomparably finer shooting than the whole fleet at Santiago, which made less than four per cent at a two-mile range.

Then it was "all aboard" for the "Delaware," and after another four or five miles of nautical gymnastics (the behavior of these steam cutters in the lumpy seas of the Chesapeake and on the southern drill grounds was something that must be seen and felt to be understood—our particular boat did everything on that trip but stand on its head and sit up on its stern), we boarded the "Delaware," to hear its gunnery officers and everybody else connected with the ship bewailing the fact, forsooth, that they had not done better shooting! To me the work, in view of the great range, had seemed to be truly wonderful. As I was merely a landsman, however, I had to be content to believe that they considered their shooting to have been indifferent, and that by giving more time between salvos for the spotter's directions to be plotted and sent to the gun stations, they could have greatly bettered the performance.

It is this setting of an exceedingly high standard—this determination to be satisfied with nothing short of the best possible results—that enables our ships to shoot accurately and swiftly at ranges that are not attempted in any other navy in the world. "The first salvo that lands will practically win the fight," is a statement that I heard frequently repeated during that two weeks' cruise with the Atlantic fleet, and I saw enough, that day, to satisfy me that, as matters stand, our ships would drop their shells upon an enemy long before he could hope to make any effective reply.

(To be Continued.)

The Current Supplement

THE front page of our current SUPPLEMENT, No 1869, shows a fine illustration of a rather remarkable bucket chain excavator at work in a Hungarian cement pit.—A peculiar amalgam which appears to consist of a mixture of mercury with the radicle ammonium, has been known since the days of Berzelius. Its true character has long been a matter of dispute, and is of interest as furnishing an apparent example of a compound radicle possessing true metallic properties. The subject of such synthetic metals is discussed by Prof McCoy.—An article reproduced from *Nature* deals with the hydro-electric plants of Norway and their application to electro-chemistry.—A catalytic process for effecting the direct union of hydrogen and nitrogen to ammonia has been worked up by Prof Haber. An account of this important development has been given by J. A. McDermott.—We have all of us at one time or another twanged the spokes of our bicycle to determine whether they were in proper condition. A similar but more elaborate test is now applied to the wires of aeroplanes, according to an invention of Capt F. Largier, which is described and illustrated in this current issue.—A most interesting review of recent developments of astronomy is given by J. S. Plaskett.—An illustrated article deals with the varied uses of the royal palm, one of the most striking vegetable features of Cuba.—The fruit industry in the West has grown to gigantic dimensions. A single frost may cause vast losses. Prof. McAdie has published somewhat extensively on the subject of frost protection in fruit orchards. Some of his work, illustrated with photographs furnished by him, is reported in a brief article.—The article on caisson sickness is brought to its conclusion in a second installment.—Those interested in locomotive engineering will find valuable information in an article on a new fourteen-wheel express locomotive.—A high speed cast-iron flywheel of remarkable design is described and illustrated in an article derived from *Power*.—The versatile genius of Swedenborg led him, among other things, to evolve some plans for a flying machine. This historical curiosity is reproduced from a publication of the Swedenborgian Association.

Death of Eugene Ely

FLYING at the State Fair Grounds, Macon Georgia, on the 19th of this month, Eugene Ely, in a Curtiss biplane, lost control of his machine and dashed to earth. As the machine neared the ground, Ely attempted to leap clear of the machinery, in this he was partially successful, but the impact was sufficient to crush him so badly that he died shortly afterward. Eugene Ely joined Glenn H. Curtiss in the summer of 1910. Last November he sprang into fame when he launched his aeroplane from the U. S. S. "Birmingham," and flew to shore, eight miles away. In January he reversed this feat by flying from shore to the armored cruiser "Pennsylvania," landing on a special platform built on the deck of the vessel. He was with the army aviation corps at San Antonio, Texas, where his work at scouting was notable.

The Development of Spitzbergen

PRESS reports from Copenhagen state that the total export of coal from Spitzbergen this year will amount to 2½ large cargoes, and it is expected that fully 100 will be exported next year. The political status of Spitzbergen is still undetermined, but it has been fully surveyed by the Norwegian government, which is also about to open a wireless station there, and it is evident that Norway will do its utmost to establish sovereignty over this far northern country. It is stated that the Norwegians have discovered new mineral deposits, the situation of which is kept secret.

Valuable Books

The Scientific American Cyclopedia of Formulas
Edited by ALBERT A. HOPKINS. Octavo, 1078 pages. 15,000 Receipts. Cloth, 65.00; half morocco, 86.50
¶ The valuable work is a careful compilation of about 15,000 selected formulas, covering nearly every branch of the useful arts and industries. Never before has such a large collection of valuable formulas, useful to everyone, been offered to the public. Those engaged in any branch of industry will probably find in this volume more than a hundred uses for their respective callings. Those lines of scientific research which have not been practiced on a small scale, will find hundreds of most excellent suggestions. It should have a place in every laboratory, factory and home.

Handy Man's Workshop and Laboratory
Compiled and edited by A. RUSSELL BOND. 12mo., 467 pages, 370 illustrations. Price, $2.00.
¶ This is a compilation of hundreds of valuable suggestions and ingenious ideas for the mechanic and those mechanically inclined, and tells how all kinds of jobs can be done with home-made tools and appliances. The suggestions are practical, and the solutions to which they refer are of frequent occurrence. It may be regarded as the best collection in a single volume of resourceful men published, and appeals to all those who find use for tools either in the home or workshop. The book is fully illustrated, in many cases with working drawings, which show clearly how the work is done.

Any of these books will be sent, postpaid, on receipt of advertised price

A Correction

To the Editor of SCIENTIFIC AMERICAN.

In my article on the Diesel engine, on page 314, next to the last paragraph, the statement is made "On the other hand, in an engine with eight cylinders, one cylinder may not become inoperative without affecting the power of the engine to a very great extent." The word *not* in this sentence is an error, as the point to be made was that an engine having as many cylinders might run with one cylinder inoperative without affecting the power, to any serious extent.

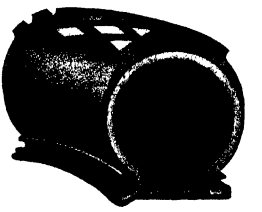
HAYNER H. GORDON.

October 7th, 1911.

Roots in Sewer Pipes

To the Editor of SCIENTIFIC AMERICAN.

I noted with interest to-day the illustration and article on page 281 of the SCIENTIFIC AMERICAN, referring to roots in sewer pipes, and a shield to prevent their entrance. In passing, I should like to remark that so far as my experience goes, sewer pipes are cemented together, a "baby" or pad of cloth or burlap being dragged through by the mason to smooth the interior of the joints.



Returning to the roots, I wish to say that while quartermaster at Fort Assininiboine, Montana, I found a main sewer pipe clogged, and a basement flooded with sewage one day. Upon digging up the pipe (it was about 10 feet down) it was found that a mass of fine, hair-like roots bunched together, completely closed it. This pipe was 8 inches in diameter, but just at this point was a junction below which the main was 10 inches in diameter, and this, too, was found almost entirely closed by root masses. In all, 36 feet of pipe (about equal portions of each size) were replaced as the roots could be cleared out only by breaking up the pipe and pulling the masses of fibers out. The largest mass was about 6 feet long and 3 inches in diameter, and when washed out and dried was very similar in appearance to a bunch of oakum. The pipe was of the best quality of glazed tile obtainable and the joints were tightly cemented; but these root-fibers had grown through the pipe at all points, and so thickly that fragments of the pipe in some cases seemed to support a thick growth of hair. The roots came, apparently, from some small cottonwoods planted as shade trees along the road way, and the nearest were about 20 feet laterally from the pipe line. A friend of mine told me that he had had a similar trouble with eucalyptus roots in a California post, and had cured it by packing the pipes in salt. I therefore purchased all the coarse rock salt (not lump), but broken pieces) that could be obtained in the small neighboring town of Havre, Montana, and packed it about 3 inches thick below, on each side, and above the replaced pipe, completely inclosing it. In the dry soil of that country this mass of salt should not soon dissolve, and the earth immediately around the pipe would remain heavily "salted" for a long time to come. The cost was only a few cents per foot, and it is not easy to see how any roots could pass such a barrier.

Durham, N. H. G. W. EDGERLY.

A Curious Meteor

DR. MAX WOLF, director of the observatory of Heidelberg, reports in *L'Astronomie*, that on the night of May 22nd, he observed a faint meteor moving from east to west across the constellation Aquila. Its diameter was about 15 minutes of arc. It passed rapidly over the star Gamma Aquilæ, and disappeared, leaving behind it a faint trail which vanished almost immediately. The remarkable feature of the observation was that the star Gamma remained invisible for fully 3½ seconds after the meteor and its train had disappeared. The obvious explanation is that the meteor left behind it a trail of opaque and non-luminous matter, dense enough to eclipse the star

Utter Perfection in a Non-Skid Tread

Double Thickness—Toughness—Deep-Cut Blocks—Countless Edges and Angles Combined With No-Rim-Cut Tires—

After three years of effort—after testing 24,000 treads—we offer you all you have looked for in a Non-Skid tread.

And we combine it with Goodyear No-Rim-Cut tires—10% oversize—the tires now wanted by every man who knows.

The Winter Tire

In 1908 we started our experts at perfecting a Non-Skid tread. A tread to get rid of ruinous chains and petty non-skid devices.

Our instructions were these:

"It must be made without metal, for rubber and metal never combine, and the friction between them soon runs a tread.

"It must be an addition to our regular tread.

"It must be immensely effective on any sort of slippery road. And it must remain effective as long as a thick, tough tread can last.

"It must be a fitting addition to features with Goodyear No-Rim-Cut tires."

Here's the Result

Here is the tread they created. An extra tread, almost as thick as our regular tread, onto which it is vulcanized. A double-thick tread, nearly puncture-proof.

Made of the toughest sort of rubber, as impervious to wear as rubber ever can be. When it does wear off, there's our regular tire left below it.

The blocks are deep-cut and enduring. They are wide at the base, so the load is spread over as wide a surface as it is with the smooth-tread tire. They present to the road surface edges and angles in every direction.

The grooves can't fill up and the air rushing through them keeps the tire cool—saves the danger of friction heat.

And the tread is white. You have never seen a device against skidding which compares with this ideal tread.

On No-Rim-Cut Tires

But the greatest fact is that this tread is combined with our famous No-Rim-Cut tires. These patented tires have quickly become the most popular tires on the market. Over 7,000,000 have been sold to date.

The control of this tire in the past two years has multiplied our tire sales by six. And we are equipping ourselves for the coming season to build 4,800 per day.

One important fact is that these tires can't be rim-cut. With the old-type tires—the clincher tires—23 per cent of all rim-cut tires are rim-cut. Such a tire, if punctured, may be wrecked in a single block.

The myriad of motorists who use No-Rim-Cut tires avoid all of this cost and worry.

10 Per Cent Oversize

Then No-Rim-Cut tires are 10 per cent over the rated size. The method of fitting permits this. That means 10 per cent more air—10 per cent added carrying capacity. And that, with the average car, adds 25 per cent to the tire mileage.

These two features together cut tire bills in two. Yet No-Rim-Cut tires cost just the same as other standard tires. They fit any standard rim. And they come if you wish, with the best Non-Skid tread ever put onto a tire. How can you afford to use lesser tires?

GOODYEAR
No-Rim-Cut Tires
With or Without Non-Skid Treads

"The most interesting romance for Americans is America's own story."

A History Of the American People

By WOODROW WILSON

Ph D, Litt D, LL.D

Former President of Princeton University

WOODROW WILSON

DO you know that Woodrow Wilson has written the most scholarly and most readable narrative History of the United States that our country has yet produced?

The History is in five volumes, is profusely illustrated with maps, plans, pictures, etc., and is written with such delightful gracility of style that, with all its authority, it reads like an enticing romance. Woodrow Wilson put half a lifetime of research into that great work, and the result is a wonderful picture of the growth of our country from the days of Columbus down to the accession of Theodore Roosevelt.

The object of this advertisement is to make to you a special half-price offer. You may have the books at just half the regular price, you may send them back to us if you don't like them, and you may have a year's subscription to Harper's Weekly (or Harper's Magazine) included without any additional payment.

The price is **$12.00**, including the periodical, and the entire five volumes come to you as soon as you send us **$1.00**. It's a great chance.

The most perfect series of maps in color ever published, showing the territorial growth, political changes, and general development of the United States. There is a full-page portrait of every president from Washington to Roosevelt, fac-simile reproductions of rare manuscripts, state papers and governmental records, together with numerous illustrations by Pyle, Remington, Fenn, Chapman, Christy, and many others. The books are bound in a manner befitting the importance of the work. A high-grade paper has been used and no expense spared.

A New Edition in Five Volumes

PREPARED WITH A VIEW TO POPULARIZING THIS GREAT WORK.

A Catalogue of Our Standard Sets of Books will be sent upon request.

HARPER & BROTHERS
Franklin Square
New York

Gentlemen: Please send me, all charges prepaid, A HISTORY OF THE AMERICAN PEOPLE, Five Volumes, Cloth Binding, subject to ten days' approval, and also enter my subscription to HARPER'S for one year, for which I enclose $1.00 and agree to send you $1.00 a month until the total price, $13.00 is paid, if the books are accepted by me.

S.A. 10-28

In the November Scribner

NOTHING that **Gen. Frederick Funston** has written is more replete with dramatic interest than the story he tells in this number of **"The Capture of Emilio Aguinaldo."** For sheer adventure and absorbing plot it would be hard to match it in any romance by Dumas.

Thomas Nelson Page writes of "General Lee and the Confederate Government." This is a most important and interesting contribution to the history of the war between the States, and gives a new impression of the tremendous difficulties that beset and handicapped the great Confederate General in his relations with the administration.

A second article on **Cleveland's Administrations**, by JAMES FORD RHODES, deals with his attitude on the Silver Question and the Venezuela Boundary Dispute.

Two unusual stories: **John Flint, Deputy Chief**, by LAWRENCE PERRY—the story of a fireman. **A Mail-Order Cowboy**, by Lieut. HUGH JOHNSON.

MADAME WADDINGTON has written **An Impression of Coronation Week**, an intimate personal impression of the scenes and the many notable people she had the privilege of knowing and meeting.

Fox and Drag Hunting in the United States is the subject of artist HENRY R. POORE'S article which will be illustrated by his own paintings, a number of them in color.

The second installment of A. E. W. MASON'S fascinating serial **The Turnstile**. The story opens with a dramatic earthquake in the Argentine and then shifts to England.

RALPH D. PAINE describes **The Great Port of London River**. The wonderful waterway from London Bridge to the sea. Illustrated.

Special Offer: For the next three months the publishers of SCRIBNER'S MAGAZINE offer unusually attractive inducements to any one who secures a specified number of subscriptions to the Magazine. Agents wanted in every town. Write now for Booklet A, giving full particulars. Address SCRIBNER'S MAGAZINE, New York City.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

Greatest Naval Review in American History

THE avowed policy of the Navy Department in gathering together the mighty fleet which is now assembled in the North River is to stimulate the interest of the taxpayers, by showing them, in one imposing object lesson, just what it is that the country has to show for the millions of money which have been expended during the past twenty years in building up a navy. We can conceive of no more effective way of doing this. Tabular comparisons and descriptive articles can do something in giving an adequate idea of naval strength—photographs of the ships will deepen the impression, but the only effective way to produce a sufficient conception of the number, size and power of the ships of a fleet is to line them up for a great naval review of the kind that is taking place this week in the fairway of the North River.

There have been some notable reviews during the era of our new navy, such, for instance, as that during the Columbus celebration, at the Jamestown Exposition, and in Long Island Sound, off Oyster Bay; but none of these compares in the number and power of the ships assembled with this great marine spectacle at New York. It is an interesting fact that, as far as the battleships are concerned, there will be found in line representatives of practically every type of American battleship that has been built during the past two decades.

Taking the ships in their historical order, we have first the "Indiana" and "Massachusetts," whose keels, together with that of the sister ship "Oregon," were laid in 1891. These ships, carrying four 18-inch and eight 8-inch guns on a displacement of a little over 10,000 tons, embodied a distinctive characteristic which has marked all American battleship design, namely, the exceptional weight and power of the battery. Recently reconstructed and furnished with the modern system of range-finding, with their gun mechanisms considerably modernized, these ships are still valuable for the second line of mobile defenses. The "Iowa," of 11,346 tons displacement, date 1897, was our first ship to carry the 12-inch gun. She mounts four 12-inch and ten 8-inch guns. The next class, "Kearsarge" and "Kentucky," 1898, is not represented in the review, nor are the three vessels of the "Alabama" class. The "Maine," however, is present, as representative of a class of three ships (date 1899), the other two being the "Missouri" and the "Ohio." In the "Maine" class as in the "Alabama" class of three ships which preceded, the 8-inch gun is missing, and a weaker battery of 6-inch guns is substituted. On a displacement of 12,500 tons the "Maine" carries four 12-inch and sixteen 6-inch guns.

Next in chronological order is the "Georgia" class, of which four ships, the "Georgia," "Nebraska," "New Jersey" and "Virginia," are present. It was around these ships that a fierce technical controversy raged, the bone of contention being the superposed turret, in which a pair of 8-inch guns is mounted above a pair of twelves, within a single double-deck turret. The "Georgia," 1901, is a vessel of 15,000 tons displacement and 19 25-knot speed. She mounts four 12-inch, eight 8 inch, and twelve 6-inch guns, a truly formidable battery, and it is but fair to state that, in spite of the limitations of the double-deck turret, certain of the heavy rifles so mounted have made some of the finest scores during target and battle practice.

The largest class among the battleships is that which is named after the flagship of Admiral Osterhaus, the "Connecticut." Six representatives of this design are present, the "Connecticut," "Louisiana," "Kansas," "Minnesota," "New Hampshire," and "Vermont." The keels of these ships were laid in 1903 and 1904. They displace 16,000 tons, and they all attained their trial speed of 18 knots, and generally exceeded it by from half to three-quarters of a knot. They carry an unusually heavy battery of four 12-, eight 8-, and twelve 7-inch guns, the last named being an armor-piercer up to considerable ranges. The completion of the "Connecticut" class marked the close of the pre-dreadnought period. The "Idaho" and "Mississippi," 13,000 tons, 17 knots, are small editions of the "Connecticut."

Of about the same displacement as the "Connecticut," but distinguished by the fact that they were the first all-big-gun ships to be built for our navy, are the "Michigan" and the "South Carolina," work upon which commenced in December, 1906. In the history of the dreadnought period these two ships will be distinguished as having been the first to introduce an arrangement of the big-gun battery, which was destined ultimately to be adopted in every navy of the world. The method may be described as "center line position and superposed firing," in which all guns are placed on the longitudinal axis of the ship, and the turrets are mounted in pairs, enabling the inboard turret to fire its guns above the roof of the turret farther outboard. Severely criticised at its first presentation, this system presented advantages so fundamental that it was bound ultimately to be accepted as the most effective compromise for securing broadside fire for every gun, and a sufficient concentration of end-on fire. The displacement of the "Michigan" and "South Carolina" is 16,000 tons. Their speed is over 18¾ knots, and they carry eight 45-caliber 12-inch guns in four turrets, and a torpedo defense battery of twenty-two, 50-caliber, 3-inch guns, which make up what they lose in weight and penetration by being carried in a lofty superstructure where they can be fought in any weather.

The first dreadnoughts, in size as well as gun power, to be built for our navy, are also moored in line. These are the "North Dakota" and the "Delaware," 1907. Our naval constructors were particularly happy in drawing the lines of these very fine ships. Visitors to the fleet will take note of the lofty forecastle deck with its pair of turrets carrying their guns 32 and 38 feet above the water line; and they will note also the long unobstructed sweep of the main deck, with its three turrets and six twelves. These two ships, with their larger sisters, the "Utah" and "Florida," are to our thinking, the handsomest battleships afloat to-day. On a displacement of 20,000 tons, they combine a speed of 21 knots with a battery of ten, 45-caliber, 12-inch and fourteen 5-inch guns, and the large bunker capacity of about 2,700 tons of coal. The "North Dakota" has the distinction of being the first turbine-driven battleship built for the United States Navy. The "Utah" and "Florida," 1909, fresh from the builders' hands, are the largest ships in the review. They embody certain valuable improvements over their predecessors. The displacement has been increased to 21,825 tons. Though the contract speed is a quarter of a knot less, on trial both ships made over 21 knots. They carry a battery of ten 12-inch, 45-caliber guns, and sixteen 5-inch.

The armored cruiser is represented by two fine vessels of the pre-dreadnought period, the "Washington" and "North Carolina," date, 1908 to 1905; displacement, 14,500 tons, speed 22¼ knots, and armament four 10-inch and sixteen 6-inch guns. These shapely vessels compare favorably with foreign armored cruisers of their time; but we could wish that the United States Navy included three or four dreadnought-cruisers of the "Inflexible" and "Von der Tann" type, whose speed and power may possibly prove to be the deciding factor in the next naval war.

Another interesting cruiser is the scout "Salem," one of three fast scouts, the "Birmingham," "Chester" and "Salem," of 3,750 tons displacement, and from 24 1/3 to 26 1/2 knots trial speed. In view of the fact that foreign navies have armored cruisers of greater speed and seaworthiness, opposing 12-inch guns to the 5-inch pieces of our scouts, it can be seen that they have been outbuilt and their field of usefulness must be extremely limited.

Very imposing is the fleet of twenty-two destroyers. Swift and sea-worthy, having the power and size to enable them to steam far and fast, even in heavy weather, these vessels must be considered as among the most efficient, both in themselves and in the way in which they are handled, of the unarmored craft of our navy. They range in size from 420 to 740 tons, and in speed from 28½ to 32½ knots. The largest of them are nearly 300 feet in length, and their full-load displacement reaches 900 tons.

Probably nothing in the review will excite more lively interest than the eight submarines, among which are included some of the latest and most successful of these craft. It is unfortunate that such an atmosphere of mystery and risk surrounds these vessels in the public mind. The maneuvers of the past year have shown them to be thoroughly seaworthy, absolutely under control, and possessed of powers of attack far beyond the common estimate of their abilities.

The weak point in the composition of our navy is its great deficiency in auxiliary ships, such as colliers and supply ships of the many and various kinds that are necessary to render the operations of a fleet effective. The eight auxiliary vessels present at the review are all converted merchant vessels, and to this extent they are necessarily makeshifts. Congress should make liberal appropriations both for supply ships and for large and speedy colliers, both types being designed specially for their several duties.

Urgently needed, also, is a large addition to our fleet of destroyers. The proportion of destroyers to battleships, as estimated by the leading naval powers, is four to one. Hence the battleships now in the North River should be accompanied by some one hundred of these craft. As a matter of fact, we have but thirty-six torpedo-boat destroyers in the whole navy.

Prizes for Military Aeroplanes

THE present war in Tripoli has greatly strengthened the interest displayed by the Italians in the possibilities of the aeroplane both as a means of reconnaissance and as a weapon of offense. Its value in the former capacity has been proven beyond a peradventure. In spite of the rapidity of its passage above fortifications and lines of troops, trained observers are able to obtain not only clear mental impressions of the details of arrangement, but they also have time to secure sketches and photographs, while their speed and the great altitudes at which they can fly render them practically invulnerable.

The recent maneuvers of the French aviation corps at Verdun were considered by military experts to have been brilliantly successful. Three aeroplanes, following two different routes, flew from the fortress at Verdun to the town of Tours, which was supposed to be in a state of siege. The machines covered 115 miles without descent, flying so high (from 3,000 to 5,000 feet) as to seem mere butterflies. Their observers noted every detail of the defensive works and the movements of troops, while they could easily have destroyed the captive balloon, which was the only measure of defense taken against them.

Besides its many apparent advantages, one authority mentions, also, that this means of scouting is more humane than older methods, since fewer scouts are needed, and their probable loss of life is far less.

As a weapon of offense, however, the aeroplane is still in a state of development, and there are divergences of opinion as to its ultimate effectiveness. Capt. Hildebrandt, the well-known German expert, is of the opinion that it can never take the place of the dirigible in destructive operations on a large scale. But the enormous comparative cost of the dirigible, with its greater vulnerability, and the difficulties of control when landing in boisterous weather, operate against its use, and give an impetus to the efforts being made to increase the offensive potentialities of the aeroplane.

An important step has lately been taken toward the furtherance of this aim. In a formal letter to the President of the Aero Club of France, a fund of 150,000 francs ($30,000) has been proffered by MM. Michelin to provide prizes for successful bomb-dropping from aeroplanes. The fund provides for four prizes. To win the first prize of 50,000 francs the aviator must carry five projectiles weighing 44 pounds each; must fly at a height of 650 feet or more; and must place his missiles, one by one, within a circle having a radius of only 32.8 feet. The prize will be awarded to the contestant placing the largest number of projectiles in the circle during a single flight. The second prize, of 25,000 francs, is to be won by the man who, flying at a minimum height of 3,280 feet, shall place the most projectiles within a rectangular area of 328 x 32.8 feet. The time limit for these two prizes expires August 15th, 1912. The limit for the remaining prizes is extended to August 15th, 1913, and the donors reserve the right to modify the conditions for these.

The results of the contests for the new Michelin prizes will be awaited with much interest especially since an American officer, Lieut. Riley W. Scott, has gone abroad with his bomb-dropping apparatus (described in our last issue), which is to be entered in competition.

The Heavens in November

Four Comets Now in Sight

By Henry Norris Russell, Ph.D.

IT IS a very unusual thing that two comets, conspicuous to the naked eye, should be in sight at once. Such was the case, however, during the early part of October, when Brooks's comet was still a prominent object in the evening sky, and could also be seen before dawn, while farther to the south, in the morning sky, appeared another comet, of about the same brightness.

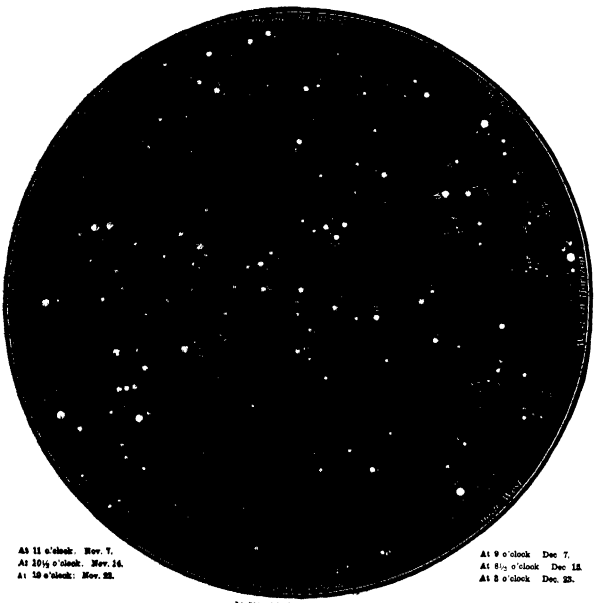
This latter object, discovered by the Russian astronomer Beljawsky on September 28th, reminds one in some ways of the great comet of January, 1910. Both were first observed as conspicuous naked-eye objects, rising shortly before the sun, and in both cases it was some time before satisfactory observations of position could be obtained, owing to the difficulty of seeing the nearby stars (which serve as reference points) upon the brightly illuminated morning sky.

A satisfactory orbit has by this time been computed, which explains why the comet was not seen sooner. It was in perihelion, at a distance of 28 million miles from the sun, on October 10th. Three weeks earlier it was more than twice as far from the sun, and probably less than one-quarter as bright. Moreover, its orbit stands almost at right angles to the plane of the ecliptic, so that it came from far south of the sun, and remained south of him (and hence in a very unfavorable position for northern observers) until about the time of discovery. At the date of writing it is in the evening sky, in 15 hours R. A. and 3 degrees south of the equator and sets about 1½ hours later than the sun. On November 1st it will be almost due west of the sun, at a distance of some 25 degrees, and will still be observable; but, being already twice as far from the sun as at perihelion, and remoter, too, from the earth it will not be at all conspicuous, though it may be followed telescopically by southern observers for some time. Brooks's comet, which passed north of the sun on October 13th, at a distance of 36 degrees, is now a fine object in the morning sky. On November 1st it will be almost exactly on the celestial equator, not far from the star Gamma Virginis, and will rise fully two hours before the sun.

Its head, at last reports, was of the second magnitude, and its tail 20 degrees long; so that it will be well worth getting up to see, before the moon comes into the morning sky. Later in the month it recedes from us and from the sun, gets more and more nearly behind the latter, and disappears.

Still a third comet, discovered by Quenisset on September 23rd, is under observation. This one requires the aid of a field glass, at least, to make it visible. Its orbit is likewise highly inclined to that of the earth, but its distance from the sun at perihelion (on November 12th) is 72 million miles. At the beginning of November it is in 15 hours 45 minutes R. A. and 13 degrees north declination, and is moving south and a very little east, at the rate of 1 degree a day. This puts it 1½ hours west and 27 degrees north of the sun, so that it will be easily observable. It will probably be of about the seventh magnitude.

A faint periodic comet, first discovered by Borrelly in 1905, has been recovered on its return at certain southern observatories, but, being visible only in the most powerful telescopes, is of little interest to us.



The Heavens

With the present month, a slight change is made in the manner in which the star-maps of our annual sequence are used. Up to this time they have shown the appearance of the sky during the early evening in the month of publication, or the later evening hours of the preceding month. There are some advantages in choosing our assumed hour of observation a little later, so that the same stars may still be seen, before twilight, during the month following that for which these articles are published. From this time, therefore, our map will show the sky as it appears at 10:30 P. M. in the middle of the month of publication, and at 8:30 in the middle of the next month.

At these hours, then, in November or December, the heavens will appear as the accompanying map shows them. The Great Bear is low in the northeast, and Draco and Ursa Minor are beneath the pole. Cassiopeia and Cepheus are high up, just west of north. The brilliant Vega is setting in the northwest, and the cross of Cygnus stands erect, just to the left. The great square of Pegasus is the most conspicuous object in the western sky. Below it lies Aquarius, the constellation represented in our initial letter. This is one of the ancient signs of the zodiac, but contains no bright stars. Its most prominent group is a small Y (lying on its side) formed by the stars ζ, γ, and two others. This represents the water jar from which the Water-Bearer pours forth a stream marked by small stars too faint to be shown on our map, which flows downward, first to the right and then to the left, till it is swallowed by the Southern Fish, whose one bright star, Fomalhaut, is now low on the southwestern horizon. Of telescopic objects in Aquarius, we may mention the star ζ Aquarii (the middle one of the Y) a fine slow binary pair, separated by 3.5 seconds, whose period of revolution is probably a couple of thousand years.

Due south is Cetus, with one conspicuous star, β, standing very much alone about 30 degrees northeast of Fomalhaut. North of this is the inconspicuous group of Pisces, and the small but brighter one of Aries, with Andromeda still higher, right overhead.

The most brilliant region of the whole heavens is now well up in the southeast, where Sirius has just risen. Orion is resplendent above him, and Taurus shines still higher up. Mars and Saturn, which are at present between Taurus and Aries, add their luster to the spectacle. Procyon is low down in the east, and Castor and Pollux are a little higher, and more to the north. Above them, the bright Capella marks the place of Auriga, and above this, almost overhead, is Perseus. Minima of the variable star Algol—may be observed at 8 P. M. on the 1st, 5 P. M. on the 4th, 10 P. M. on the 21st, 7 P. M. on the 24th, and so on, the eclipses coming on every third day, about 3 hours 10 minutes earlier by the clock.

NIGHT SKY: NOVEMBER AND DECEMBER

The Planets

Mercury is evening star throughout November, but being very far south of the Sun is ill placed for observation. Toward the end of the month he may perhaps be seen as he sets about 5 45 P. M.

Venus is morning star, at her very best rising in the neighborhood of 2 A. M. and getting high in the southeast before dawn. On the 16th she is in conjunction with the crescent Moon, and when nearest at about 2 P. M., will be less than a degree away. By this hour both will be low in the west, so, if we wish to see the planet in the daytime (which is perfectly easy if the sky is really clear) we will do better to go out in the forenoon, and look a couple of degrees east of the Moon.

Mars is in opposition on the 24th and is visible all night. He is farther from us than he was two years ago 47 millions miles but his high northern declination makes up for this, by carrying him high in the sky where we have to look through less of our own unsteady atmosphere in order to see him.

To find him, it is only necessary to look eastward and pick out the brightest and reddest thing in sight. With even a small telescope, he shows a considerable disk. The darker markings which are the most conspicuous features of the Martian surface can be seen fairly well with small telescopes, and these will also show that the "polar cap" is at present inconspicuous, most if not all of the polar snows having disappeared during the long summer of the Martian southern hemisphere, now near its close.

Jupiter is in conjunction with the Sun on the 17th, and is invisible throughout the month.

Saturn is just past opposition, in Aries, about 20 degrees west of Mars, and is finely placed for observation, with the ring-system opened widely. The contrast in color and brightness between the two planets is conspicuous to the naked eye.

Uranus is in Sagittarius, too low in the west at sunset to be well seen. Neptune is in Gemini, coming to meridian about 4 A. M. in the middle of the month.

The Moon is full at 11 A. M. on the 6th, in her last quarter at 2 A. M. on the 13th, new at 6 P. M. on the 20th, and in her last quarter at 9 P. M. on the 28th. She is nearest us on the 8th, and remotest on the 21th. She is in conjunction with Saturn on the 6th, Mars on the 7th, Neptune on the 11th, Venus on the 16th, Jupiter on the 20th, Mercury on the 22nd, and Uranus on the 25th.

Princeton University Observatory.

Photographic Scouting at Night

An Artist's Contribution to an Aeronautic Problem

WHILE the matter of using aeroplanes as actual fighting units in warfare is still in dispute, there is no question that they will play a most important part as scouts. In fact they have actually been used in this capacity by the Italian army in Tripoli. In the very earliest days of aeronautics this use of the aeroplane was suggested and pictures were published showing an army scout making sketches from an aeroplane. A later idea has been to use a camera so as to facilitate the work of the scout. It has occurred to the artist whose drawing is reproduced herewith, that photography under such circumstances would be rather difficult, owing to the fact that the machine would have to be brought within comparatively small elevation above the fortifications that were to be photographed, and would thus be an easy target for the gunners below. He believes that night photography would be better for then the aeroplane could steal into position over the fortifications, and flash its light upon them for a few brief moments while pictures were taken. The best camera for the purpose would be one adapted to take a kinematographic series of pictures. Out of the set of pictures thus taken, there would, he argues, surely be a few which would show the fortifications to good advantage as the aeroplane passed over them. The brief interval during which the searchlight of the aeroplane would play upon the fortifications might not be sufficient to enable the gunners to take accurate aim upon the aircraft. In order to increase the value of the photographs, it would be well to determine the height of the machine above the fortifications and hence the scale of the pictures. The height above sea level could readily be determined by means of a barometer, but it would not necessarily show the height above the fortifications. However, with a searchlight throwing a conical beam of fixed angle, the spot of light upon a film taken with a camera of known focus, would give an approximate index, from which the height of the machine above the fortifications would be determined. By this means it would be possible to make an accurate survey of the fortifications with a minimum exposure of the aeronauts.

Another method of discovering the height of the aeroplane above the fortifications, the artist suggests, is to have two searchlights placed at opposite ends of the machine and mounted to move together in such a way that their beams would intersect always at a fixed distance below the aeroplane. The height of the aeroplane above the fortifications would then be shown by the size of the intensely illuminated spot produced by the overlapping portions of the beams of light.

MAKING NIGHT PHOTOGRAPHS FROM AN AEROPLANE

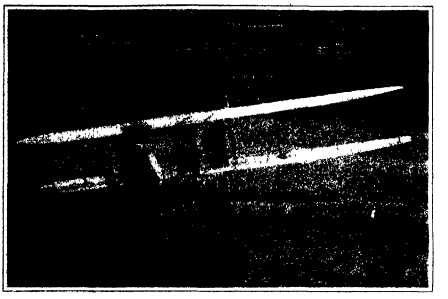
The Recent Gliding Experiments of the Wrights

By Grover Cleveland Loening

A GREAT and widespread interest has been aroused by the experiments now being conducted by Orville Wright at the scene of the first great flights by man, Kitty Hawk, N. C. Many reports have been circulated with regard to the real purpose of these experiments, some of them no doubt exaggerated and perhaps amusing to the taciturn Dayton inventors. Orville Wright's "vacation" is nevertheless an occasion upon which the eyes of the aviation world have good cause to look sharply. Other than to teach Ogilvie how to glide, and to test a "tail" glider, Orville Wright is evidently bent upon continuing in a logical manner the exhaustive experiments in free flight conducted over so many years by his brother and himself.

The most startling achievements that have resulted from this latest series of tests are briefly as follows: In a biplane glider similar in many respects to the model B Wright machine frame, but differing in the smaller size of the planes and the use of a larger rudder, and sitting upright with the usual control mechanism in his hands, the aviator has succeeded in making glides that far exceed anything done in this line before. He has attained greater heights, greater distances, and stayed aloft a longer time. The general character of the glides, however, bears much resemblance to the 1903 experiments. On Monday, October 23rd, a curious accident took place. Rising some twenty feet from the side of the hill, the heavy rear rudder appeared to become uncontrollable and to make the glider so "tail heavy" that it began to turn over and start backward, whereupon Mr. Wright climbed to an upright position of safety on the overturning machine with such excellent judgment that when the apparatus struck the ground and smashed Mr. Wright emerged unhurt. This experience suggests that many of the fatal accidents in aviation were avoidable by the same *sang froid*.

Of course the lighter loading would make the time of fall in such an emergency, longer as well as render the shock lighter.



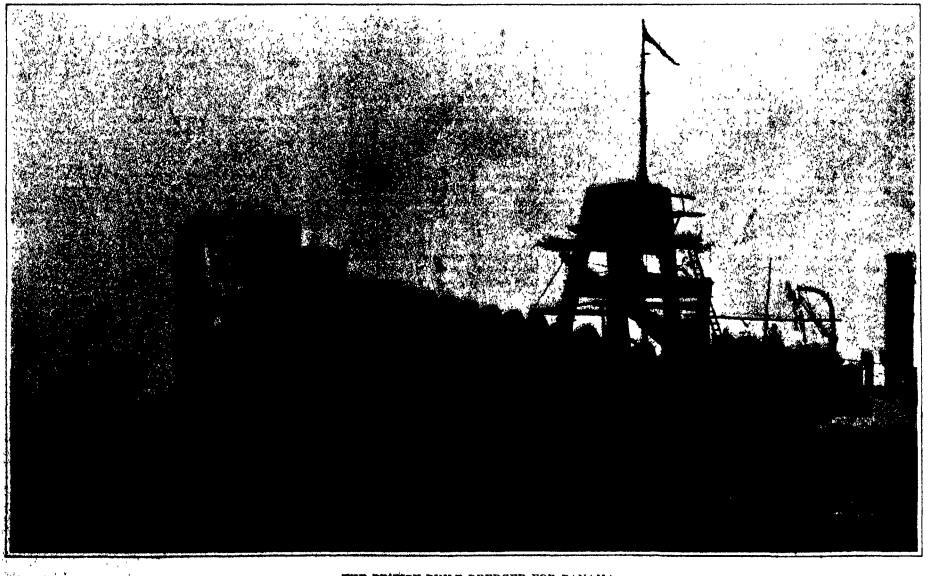
On the next day, October 24th, a feat that has long been predicted and looked forward to was accomplished. With consummate skill Orville Wright soared aloft into the teeth of a supposedly fifty-mile gale, and succeeded in not only soaring for a period of almost ten minutes but in actually advancing into the wind. This great flight was made over the side of the hill facing the wind so that the air currents must have had a decidedly upward trend. The distance covered by the flight was a quarter of a mile and the height attained estimated at 200 feet above the surface. Though the results are astonishing to many, those familiar with the nature of air currents expect even more startling performances at an altitude three or four times as great.

It is hardly possible as reported that the object of these tests was to try out a device for automatic stability. There is not yet enough known of wind cur-

tants and their motions to enable a thoroughly successful device of the sort to be even conceived. It may be definitely assumed that the purpose of Orville Wright's experiments are primarily to learn more of wind conditions. Many problems such as the avoiding of "side-slipping" still remain to be solved. Not until every possible vagary of the air currents becomes known, can a device for automatic stability be designed and be successful.

It is due partly to the peculiar phenomenon often called "Lilienthal's Tangential," that a glider with cambered planes can not only remain stationary but in a wind of great enough upward trend can be made to actually advance without the exertion of any motive power whatsoever. This would appear offhand like perpetual motion, but it must be borne in mind that the huge energy of the rising current itself is the source of power. The phenomenon referred to is merely, that at certain angles, the total air pressure acting on a plane ceases to act in a line normal to the plane or its chord and instead the line of action of this force takes a position well in front of the normal, the pressure thus materially acting in the dual role of a supporting *and propelling force*.

Octave Chanute, early in 1909, pointed out in a masterly way the manner in which this problem of soaring could be solved and many experts since then who have investigated the problem are convinced that it is a feasible one, even though it appears to defy physics. These experiments of the Wrights are therefore likely to bear fruitful results, results that may eventually become of the utmost importance. It will be interesting to note what changes in their standard design the Wrights will make as a result of these tests.



Orville Wright starting from the top of a sand dune with his new glider.

The British-built Dredger for Panama

Hopper Capacity 1,200 Tons of Dredging, Bucket Ladder will Reach to Depth of 50 Feet.

By Our English Correspondent

ONE of the vessels around which an acute political—we can scarcely call it economic—controversy has raged in America for some time is the "Corozal," an extremely powerful bucket dredger which has been built by Messrs. Wm. Simons & Company (Limited), of Renfrew, Scotland, to the order of the United States Government, for carrying out some of the most arduous underwater cutting to be done in connection with the Panama Canal. The vessel has a hopper capacity of 1,200 tons of dredgings and the bucket-ladder is designed for dredging up to a depth of 50 feet. It is propelled at a speed of 10 knots per hour by two sets of triple-expansion, surface-condensing engines, supplied with steam from two cylindrical, multitubular boilers, constructed to Lloyd's requirements for a working pressure of 180 pounds per square inch. A complete outfit of the most modern auxiliary machinery is provided in the engine room, including independent air pumps, circulating pumps, feed pumps, feed heater and filter, etc. The dredging gear is of the most massive description and is arranged to give three speeds of buckets to suit the various kinds of material to be dealt with. The dredging gear can be driven by either of the main propelling engines. Two sets of buckets are provided, one of 54 cubic feet capacity for dredging soft material and one of 35 cubic feet capacity for dredging stiff clay. The bucket ladder is a steel girder of exceptional strength and an idea of the great strength of the bucket chain may be conveyed by the statement that the ladder with its chain of buckets, links and pins, weighs upward of 240 tons. The upper end of the bucket ladder is supported on an independent pivot shaft and the lower end is controlled by powerful steel wire-rope tackle and independent steam hoist gear, which is designed for raising the latter at a speed of 10 feet per minute. Steam maneuvering winches are fitted at bow and stern, each driven by independent, two-cylinder engines and each barrel is fitted with friction clutch and brake to enable the mooring chains to work independently of each other, or simultaneously, as may be required. Shoots are provided for loading into the vessel's own hopper, also overboard shoots controlled by independent steam winches, for loading into barges alongside. The hopper doors are controlled by independent hydraulic gear. This dredger, "Corozal," was launched on the Clyde in September and she is to undergo severe tests before being despatched on her voyage round South America to the western end of the canal. Before leaving British waters, she will be tested, first in lifting sand and mud from the bottom of the Gareloch, off Helensburgh, and, afterward, she will be taken back to Renfrew where the buckets will be changed, and subsequently she will be sent to Belfast and tested in the hard clay of the Musgrave Channel. The dredger was constructed to Lloyd's full requirements and Mr. T. M. Post and Mr. A. V. B. Candlet have superintended the construction of the dredger on behalf of the United States Government for the Panama service.

THE BRITISH-BUILT DREDGER FOR PANAMA

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them

Why is the Flesh of the Watermelon Red?

IN a recent number of the *Rundschau*, Prof O. N. Witt makes some very interesting reflections on the colors of living objects of nature We reproduce here in abridged form some of the essential points

Modern science teaches us that everything in nature has its definite purpose The naive point of view of past ages, according to which a well meaning Providence has adorned the world about us in order to minister to our pleasure, has had to give way to the inquisitive gaze of modern scientific investigation We now know that the refreshing green of the woods and meadows is not provided for our enjoyment, but for the serious and practical purpose of plant nutrition, the flowers display their bright colors to attract the insect that carries the pollen from stamen to stigma, the Alpine hare is snow colored so as to be hidden from the sight of his enemy, while the lion is tawny and the tiger striped, in order that he may be undistinguishable from the natural background as he lies in wait for his prey All these facts are plain enough and we admire the perfection of these adaptations, and this feeling of intelligent appreciation we now feel to be of greater worth than the ignorant worship of yore True it is that Darwin's brilliant hypothesis of the "survival of the fittest" does not satisfactorily explain just how the different organisms set about acquiring the various characteristics and colors which are now so useful to them. Here and there an instance may be found where the process of adaptation is explicable enough, but there are many cases which baffle the ingenuity of biologists of to-day What is still more unintelligible, and has apparently never been explained, is that nature is often lavish in dispensing brilliant colors where, in the natural course of events, they seemingly can never be of any account whatever The number of instances of this kind are innumerable, just a few may be picked out for illustration here Why, for instance, is the blood of all warm blooded, and of many cold blooded, animals, red? It is not intended, under normal circumstances, to be visible, its principal function being fulfilled in the lungs, hidden away from sight Attention has been drawn to the remarkable analogy between the red blood pigment and the green pigment of plant leaves, but whatever may be the chemical analogy, there is no analogy whatever in the functions, for the color of chlorophyl is plainly connected with its function in absorbing light for the purpose of building up starch from atmospheric carbon dioxide In the case of hemoglobin there is no such analogous function whatever Furthermore it is known that there must be colorless substances capable of performing the functions of the blood, for many animals of the lower type actually have colorless blood Again, we may ask, why is the flesh of many animals colored? For instance, why is the salmon colored with the hue which has taken its name from this fish? No one can tell

Exactly similar conditions are met with in the vegetable kingdom Why is the red beet deeply colored, while its close congeners have a white juice? After all, neither under normal circumstances, see the light of day, so that it is problematical what useful function the color can possibly serve Then again, why does the madder root contain quantities of alizarine and allied dye stuffs that in the past have been of such great value while in modern times we have learned to manufacture them by artificial means? Of what possible use can such dye stuffs be to the plants? Consider the watermelon, covered by a thick, opaque, dark green skin We may make some sort of conjecture as to the purpose of this, it perhaps serves in keeping off some of the large animals which would devour the fruit, skin and all, and thus leaving the melon to be burrowed by worms who leave the seeds untouched But why that appetizing pink color of the flesh of the melon? It cannot serve as a charm to attract visitors, for the guest that has eaten its way through the skin needs no further attraction, after he has reached the interior The black color of the seeds may perhaps be put down as a preventive measure protecting them from sharing the fate of the rest of the fruit

The attractive and appetizing outward appearance of most fruits is generally explained by supposing that its function is to attract animals, which eat the fleshy portion and carry the seed away from the parent plant, thus aiding the distribution of the species The red cheeks of a peach are so enticing that this explanation will probably be readily accepted But why that brilliant red color where the flesh meets the kernel? The bird that picks at the flesh of the fruit does not strike this colored layer until the work is practically accomplished.

Certain trees which furnish the so-called dye woods deposit pigment by the hundredweight within their stems. The woad or indigo plant and several others contain a substance known as indican, which is normally colorless but is transformed by a fermentation and oxidation process into deep blue indigo This case is particularly puzzling, since the color of the dye stuff is not even developed in the living plant.

Perhaps no science is more replete with problems for the future to solve than biology and physiology.

The Toughness of the Chinese Physique

IN a recent number of the *Popular Science Monthly*, Prof E A. Ross discusses some peculiar characteristics of the Chinese race in its resistance to disease. That there must be a marked difference in the character of this race as compared with ours is obvious enough, when we consider that out of ten children born among us, three, normally the weakest three, will fail to grow up; out of ten children born in China about eight are doomed to die in infancy. The difference is due to the hardships that infant life meets with among the Chinese, and it need hardly be pointed out that with such rigorous selection there will necessarily result a stock displaying a peculiar hardihood Just what kind of a hardihood depends on the particular conditions of selection, as Prof. Ross brings out clearly in his article. To anticipate his conclusion, the fact is that while the Chinese resist certain diseases with remarkable power, other diseases are more fatal to them than to us. Prof. Ross collected his data by questioning a number of physicians who had practiced for a number of years in China One or two among these gave an opinion differing from the others, but by far the great majority agreed in their verdict

Where the constitution of the Chinaman excels is in his extraordinary power to resist septic infection. Some of the instances cited to illustrate this fact are almost incredible and are too gruesome to invite repetition. Amazing, also, is their response to the treatment of neglected wounds

A boy whose severed fingers had been hastily stuck on any how and bound up with dirty rags came to the hospital after a week with a horrible hand and showing clear symptoms of lockjaw They washed his hand and sent him home to die. In three days he was about without a sign of lockjaw A man whose fingers had been crushed under a cart some days before came in with blood poisoning all up his arm and in the glands under the arm The trouble vanished under simple treatment A patient will be brought in with a high fever from a wound of several days' standing full of maggots, yet after the wound is cleaned the fever quickly subsides A woman who had undergone a serious operation for cancer of the breast suffered infection and had a fever of 106 degrees, during which her husband fed her with hard water chestnuts: Nevertheless, she recovered.

Living in the super-saturated, man-stifled land, profoundly ignorant of the principles of hygiene, the masses have developed an immunity to noxious microbes which excites the wonder and envy of the foreigner They are not affected by a mosquito bite that will raise a large lump on the lately-come foreigner They can use contaminated water from canals without incurring dysentery. There is very little typhoid, and what there is, is so attenuated it was long doubted to be typhoid. All physicians agree that among the Chinese smallpox is a mild disease. The chief of the army medical staff points out that during the autumn maneuvers the soldiers sleep on damp ground with a little straw under them without any ill effects. Coolies, after two hours of burden-bearing at a dog trot, will shovel themselves full of hot rice with scarcely any mastication, and hurry on for another two hours. A white man would have writhed with indigestion. The Chinese seem able to sleep in any position. I have seen them sleeping on piles of bricks, or stones, or poles, with a block or a brick for a pillow and with the hot sun shining full into the face. They stand a cramped position longer than we can and can keep on longer at monotonous toil unrelieved by change or break

But there is another side to the comparison. There is little pneumonia among the Chinese but they stand it no better than we do, some say not so well. There is much malarial fever and it goes hard with them. In Hong Kong they seem to succumb to the plague more readily than the foreigners Among children there is heavy mortality from measles and scarlet fever. In withstanding tuberculosis they have no advantage over us While they make wonderful recoveries from high fevers they are not enduring of long fevers. Some think this is because the flame of their vitality has been turned low by unsanitary living. They have a horror of fresh air and shut it out of the sleeping apartment, even on a warm night. In the mission schools, if the teachers insist on open windows in the dormitory, the pupils stifle under the covers lest the evil spirits flying about at night should get at them. The Chinese grant that hygiene may be all very well for these weakly foreigners, but see no use in it for themselves.

From the testimony it is safe to conclude that at least a part of the observed toughness of the Chinese is attributable to a special race vitality which they have acquired in the course of a longer and severer elimination of the less fit than our North-European ancestors ever experienced in their civilized state. Such selection has tended to foster not so much bodily strength or energy as recuperative power, resistance to infection and tolerance of unwholesome conditions of living. For many centuries the people of south and central China, crowded together in their villages or walled cities, have used water from contaminated canals or from the drainings of the rice fields, eaten of the scavenging pig or of vegetables stimulated by the contents of the cess-pool, huddled under low roofs, on dirt floors, in filthy lanes, and slept in fetid dens and stifling cubicles. Myriads succumb to the poisons generated by overcrowding and hardly a quarter of those born live to transmit their immunity to their children. The surviving fittest has been the type able to withstand foul air, stench, fatigue toxin, dampness, bad food and noxious germs. I have no doubt that if an American population of equal size lived in Amoy or Soochow as the Chinese there live, a quarter would be dead by the end of the first summer But the toughening takes place to the detriment of bodily growth and strength.

To the west the toughness of the Chinese physique may have a sinister military significance. Nobody fears lest in a stand-up fight Chinese troops could whip an equal number of well-conditioned white troops. But few battles are fought by men fresh from tent and mess In the course of a prolonged campaign involving irregular provisioning, bad drinking water, lying out, loss of sleep, exhausting marches, exposure, excitement and anxiety, it may be that the white soldiers would be worn down worse than the yellow soldiers In that case the hardier men with less of the martial spirit might in the closing grapple beat the better fighters with the less endurance

In view of what has been shown the competition of white laborers and yellow is not so simple a test of human worth as some may imagine. Under good conditions the white man can beat the yellow man in turning off work But under bad conditions the yellow man can best the white man, because he can better endure spoiled food, poor clothing, foul air, noise, heat, dirt, discomfort and microbes. Reilly's endeavor to exclude Ah San from his labor market is not the case of a man dreading to pit himself on equal terms against a better man. Indeed, it is not quite so simple and selfish and narrow-minded as all that. It is a case of a man fitted to get the most out of good conditions refusing to yield his place to a weaker man able to withstand bad conditions.

A Revival in the Whaling Industry

IT is reported in the *London Financial Times* that a Tyne firm is about to dispatch a fleet of five vessels—three whalers, a factory ship, and an oil carrier—to engage in whaling in the vicinity of Kerguelen Island, where Norwegian stations are already established. From many parts of the world comes the news of an active revival in the whaling industry, which had been at a low ebb for many years. Norwegian companies are said to be reaping enormous dividends in southwest African waters, and a German company, just formed with a capital of $250,000, is about to begin operations in the same region.

About twenty Norwegian expeditions, with crews aggregating 700 men, are in the field. The Norwegian companies, as a rule, buy second-hand British steamers, and fit them out with all the most modern appliances for whale catching and trying out. The whole process of recovering the marketable products from the carcass is carried on at sea.

Upward of a dozen whalers hail from Dundee. One of these, the "Balaena," has recently declared a dividend of 34½ per cent.

Engineering

Quick Work on Panama Locks.—Over sixty-seven per cent of the concrete for all the locks of the Panama Canal is in place. At Gatun 81.5 per cent of the concrete has been laid; at Pedro Miguel over 87 per cent; while the two twin locks at Mira Flores have about one-third of the concrete in place.

Tunnel and Terminus at Montreal.—A subsidiary company of the Canadian Northern Railway has completed plans for effecting an entrance into the heart of the city of Montreal by building a three-mile tunnel under Mount Royal. A new terminal will also be constructed, in which the latest improvements in terminal facilities will be embodied. The total cost of the tunnel and terminal together will be $25,000,000.

September Progress on the Panama Canal.—The total amount of excavation on the Panama Canal for September was 2,538,764 cubic yards, as compared with 2,687,088 cubic yards in September, 1910, and 2,836,365 cubic yards in September, 1909. The grand total of canal excavation to October 1st was 150,722,962 cubic yards. There yet remains to be excavated 44,599,417 cubic yards, which is less than one-fourth the entire excavation for the completed canal.

Evidence of a Mine Beneath the "Maine."—According to a dispatch from Washington, the former chief constructor of the navy, Rear-Admiral Washington L. Capps, who recently inspected the operations in uncovering the "Maine," will confirm the report of the Naval Court of Inquiry of 1898, which stated that the condition of the wreckage led to the conclusion that the primary explosion took place beneath the hull of the "Maine" in the neighborhood of Frame No. 18.

Cape Cod Canal Open in 1913.—In a recent address before the Atlantic Deep Waterways Convention in Richmond, Commodore J. W. Miller stated that the Cape Cod Canal will be open in 1913. This important work will enable shipping to avoid the stormy passage around Cape Cod and to pass from Buzzards Bay into Cape Cod Bay by a short connection of eight miles. The channel will be 30 feet deep at high water, which is more than the depth of the Manchester and the Kiel canals.

The Lathe as a Chip Producer.—Mr. Joseph Chilton, in a paper read before the North East Coast Institution of Engineers and Shipbuilders, states that as a chip producer, the lathe is the most economical of machine tools. He finds that a well-designed lathe, under favorable conditions, produces half a pound of chips per horse-power per minute when cutting mild steel, the pressure on the tool being approximately 100 tons per square inch "area of cut"—this last meaning the depth of cut multiplied by the feed; a cut half inch deep with a one-eighth-inch feed having an area of one-sixteenth of a square inch.

Great Steaming Radius of British Submarines.—The most notable fact in the development of submarines is their increase in size and in steaming radius. This means that the submarine is approaching the day when it will accompany the fleet on the high seas, and play a most important part in the general action of the future. The British are building two new classes of submarines, one of 600 tons, and the other of 800 to 1,000 tons displacement. Sixty-six of their latest submarines have a surface radius of 2,000 miles, which is being raised to 4,000 and 5,000 miles in what is known as the new "B" and "E" classes.

Deep Submersion of Submarines.—The submarine "Salmon" has established a record for deep diving, which exceeds anything that has been hitherto accomplished in our own navy. It will be remembered that during the early summer months, the "Octopus" attained a depth of 125 feet. This has been exceeded by 19 feet by the "Salmon," which was submerged to a depth of 144 feet off Prudence Island, and remained at that depth for 20 minutes. The submarine is certainly coming into its own, as will be shown in an article by Lieut. Bingham, Commander of the Third Submarine Division, which will be published in our Naval Number of December 9th, 1911.

German Naval Activity.—A recent government paper issued in Great Britain, giving the total naval expenditures for the last ten years proves how keen is the competition in naval construction among the great powers of the world. In 1901 Great Britain expended $50,000,000 on new construction, and in 1911 the amount is $85,000,000. Germany, which in 1901 spent $33,000,000, in 1911 is spending $58,000,000 on new construction. The United States spent $26,000,000 in 1905 on new construction, and she is spending about the same amount this year. The outlay for new construction in France was about the same in both years as that of the United States. The most significant feature of this comparison is the fact that in the decade under consideration, German expenditures for new construction have nearly trebled.

Science

The Stettin-Berlin Water Route.—The new canal connecting Berlin with the River Oder (and hence with Stettin, the nearest seaport to Berlin), will, it is expected, be completed by the autumn of 1912. It will accommodate vessels up to 660 tons. Undoubtedly the commercial importance of Stettin will be much enhanced at the expense of Hamburg by this new and short water route from Berlin to the sea.

Postponement of Scientific Congresses.—Owing to the disturbed state of public affairs in Italy, several international scientific meetings that were to have been held in Rome this autumn have been postponed. According to information received by the State Department in Washington, the International Congress of Tuberculosis and the International Congress of Archæology are now expected to be held next April. The International Geographical Congress has also been postponed until next spring, but the date appears not to have been settled.

The Geophysical Journal.—Under this title the British Meteorological Office is about to add to its long list of valuable periodical publications a monthly section of the British Meteorological Year Book, which will include daily data for meteorology, terrestrial magnetism, atmospheric electricity, etc., based upon observations at the Meteorological Office observatories and anemograph stations. An annual supplement will also be published, giving hourly values. This departure is in line with the advanced policy of providing material for synoptic studies in meteorology and related sciences for the benefit of students of dynamic rather than static problems.

Canadian Asbestos.—About 82 per cent of the world's supply of asbestos comes from Canada, according to an account of this industry published in the *Chamber of Commerce Journal*. The Canadian output has increased from 380 tons in 1880 to 63,300 tons in 1909. The quarries and factories are capitalized to the amount of $24,290,000. In the Black Lake quarries, Province of Quebec, there are 45,000,000 tons of asbestos in sight. The asbestos slate or shingle industry, a development of the last five years, has grown to such an extent that it is predicted that within a short time 75 per cent of all the asbestos produced in Canada will be used in making this new roofing material.

The Jesuit Seismological Service.—In the absence of a government seismological service in the United States, it is fortunate that a number of Jesuit observatories have organized a service, which includes stations at the following points: Buffalo, N. Y., Cleveland, O., St. Louis, Mo., New Orleans, La., Spring Hill, Ala., Denver, Colo., St. Boniface, Manitoba, Santa Clara, Cal.; Spokane, Wash.; Brooklyn, N. Y., Worcester, Mass.; Fordham, N. Y., Chicago, Ill., Milwaukee, Wis.; St. Mary's, Kan. The first nine of these are in full action, sending in regular reports to the central station, St. Ignatius College Observatory, Cleveland; whence they are transmitted to the International seismological headquarters at Strassburg, Germany.

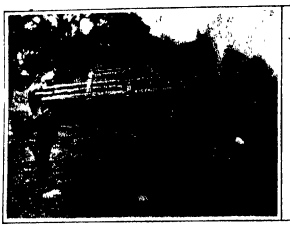
Ozone and Ball Lightning.—W. M. Thornton, writing on "thunder-bolts" in the *Philosophical Magazine*, applies this term to ball lightning—though authority for such an application is not to be found in the dictionaries. The disappearance of one of these mysterious balls is said to be always followed by a strong smell of ozone. The writer believes that the principal, though perhaps not the only constituent of a ball of lightning is an aggregation of ozone and partially dissociated oxygen, thrown off from a negatively-charged cloud by an electric surge after a heavy lightning discharge. The explosion in which the phenomenon so often terminates is explained as due to the energy liberated on the transition of ozone to oxygen.

Powdered Milk for Polar Expeditions.—The announcement that two tons of powdered milk have been ordered for the use of Dr. Mawson's forthcoming antarctic expedition has helped to bring into prominence an industry which is assuming large proportions in Australasia, especially in New Zealand. The same product was used extensively by Shackleton's expedition, and was the principal food of Prof. David's party, which reached the south magnetic pole. New Zealand powdered milk is a serious rival to condensed milk, on account of its nutritive value and especially its keeping qualities. It is said to be much superior to condensed milk for infants' food, as it is thoroughly sterilized, contains no cane or beet sugar, and, in the process of drying the milk, the casein is divided into fine particles, as in human milk. One kind of powdered milk, made entirely from skim milk, is used largely in biscuit factories and in the manufacture of milk chocolate.

Aeronautics

Aeronautics in Italy.—The American consul at Venice reports that the first Italian school for the instruction of aerial pilots has been established and subsidized by the royal government at Pordenone, a town in the province of Udine. Italy's third military airship has been under construction during the past year.

An Aeroplane Service in the Congo.—According to the London *Times*, a government subsidy of $80,000 has been voted for the initial steps in the establishment of communication by aeroplanes over regions of the Belgian Congo that are still unprovided with railways and roads. It is proposed to traverse a desert 750 miles across, and to establish landing stations 250 miles apart fitted with wireless telegraphy. Each aeroplane is to carry three passengers and a relatively heavy load of food, water, tools, etc.

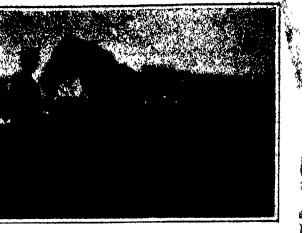


Carrying Mail by Aeroplane.—According to the report of the post office inspectors to the Postmaster General, no less than 43,247 pieces of mail matter were despatched by aeroplane from the Nassau Boulevard Aerodrome between September 23rd and October 1st. So enthusiastic has the Postmaster-General become as to the possibility of saving time and money in delivering mail in certain districts by aeroplanes, that he has asked for an appropriation of $50,000 to enable the Post Office Department to experiment thoroughly along these lines. Just as the automobile is at the present day rapidly replacing the horse in city mail delivery so the aeroplane will no doubt displace the fast express before many years have passed.

Results of the International Balloon Race.—The international balloon race which started about a month ago from Kansas City was won by Hans Gericke, the German aeronaut, who covered 471 miles. Lieut. F. P. Lahm, was second with 408 miles, and Lieut. Vogt, of Germany, third, with 350 miles. Fourth and fifth places went to John Berry and W. F. Assman, with 293 and 275 miles, respectively, to their credit, while Emile Dubonnet was sixth, with 200 miles. The French aeronaut remained in the air longer than any of his competitors but was blown back 400 miles. He has offered to wager $2,000 that he will beat any American who will come to France and fly against him between now and the first of the year.

Successful Use of Aeroplanes in Actual Warfare.—Cognizant of the excellent showing made by the aeroplanes in reconnaissance in the French and German maneuvers, King Victor Emmanuel sent to Tripoli with the armada, eight monoplanes and two biplanes. After flying over the fleet on October 23rd Capt. Piazza made a 45-minute flight in a Blériot monoplane about the neighboring country. The Arabs were awe struck when the machine swooped over them, and the theory that an aeroplane can be used for the purpose of creating panic was shown to be a correct one. The flight mentioned extended as far as the Zanzor oasis, some fifteen miles from Tripoli. Valuable information was obtained as to the disposition and numbers of the Turkish infantry.

The Trans-continental Flight.—Aviator Rodgers wrecked his machine in starting on a narrow road at Spofford, Texas, on October 25th. The day before he had covered the 132 miles from San Antonio, Texas, in 5 hours and 22 minutes, including stops of about 2 hours for repairs and the making of exhibition flights. This is the first bad smash he has had since leaving Huntington, Ind., but he remains undaunted and expects to eventually reach the Pacific Coast. Meantime, on October 24th, Robert G. Fowler has made another start in the opposite direction. He arrived at Mecca, Cal., at noon of the 24th ult., after having covered 61 miles in 68 minutes.



A New Hydro-aeroplane Record by Naval Officers.—On October 9th, Lieuts. Ellyson and Towers, of the Navy Aviation Corps, started on a flight from Annapolis to Hampton Roads with a Curtiss hydro-aeroplane. After flying five miles they were obliged to descend on account of motor trouble. Another start was made two days later, and this time the officers covered 65 miles and landed at Smith's Point, Virginia. A motor break-down terminated this second attempt. The third attempt was completely successful and was made on the 25th ult. The officers covered about 140 miles from Annapolis to within two miles of Fortress Monroe in 2 hours and 27 minutes, at the rate of nearly 60 miles an hour. The flight was made entirely above the waters of Chesapeake Bay and most of the way an elevation of 1,000 feet was maintained. The officers often shifted the control wheel from one to the other, and they were very enthusiastic over the operation of this new device which was brought out a few months ago by Mr. Curtiss and on which he has applied for a patent.

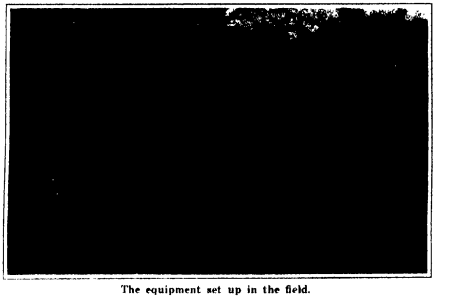
The mast packed for transit.

Wireless Telegraph Set for Cavalry

By the English Correspondent of the Scientific American

How the generator set is carried.

ONE of the recent developments of wireless telegraphy for military purposes is an equipment for cavalry use to insure a positive means of communication between bodies of mounted troops or with the main body and the commander in chief's staff

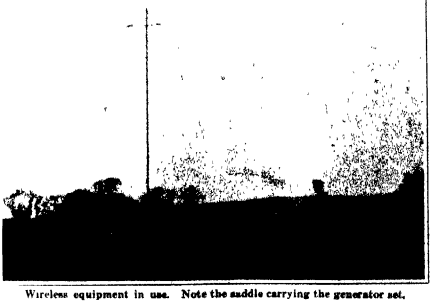


The installation is completely self-contained, comprising a small and light motor driving a dynamo a receiving and transmitting set, and a mast The whole outfit can be handled by a squad of four men and eight horses, four animals being required for the transportation of the parts One horse carries the generator set, another the transmitting instruments, the third the receiving equipment, and the fourth the detachable mast and the wire stays

The generator set is particularly interesting Secured to the saddle is a light outer framework of tube steel, with four side members projecting to serve as legs when the saddle is removed and stood on the ground Each pair of legs carries a lug and bracket near the ground to form a support on the one side for the small dynamo and on the other for the small gasoline engine Above each is fitted a semi-cylindrical tank to carry the fuel, oil etc It will thus be seen that the weight of the installation is fairly equally divided for the horse When the saddle and load is removed from the animal's back it forms a rigid structure on the ground The dynamo which is air cooled is direct coupled to the motor by a short length of detachable shafting slipped into sockets on the shafts of the engine and the dynamo respectively

The telegraphic instruments are of the latest Marconi type Both the receiving and transmitting apparatus may be packed into small compass so as to lie flat against the horses flanks The mast is built in lengths of about four feet which slip together in much the same way as the parts of a fishing rod, and when erected give a mast between 40 and 50 feet in height

The equipment shown in the illustrations is one of two that have been acquired by the Westmoreland and Cumberland Yeomanry of Great Britain and are identical in every respect with those recently employed in demonstrations in Turkey and in Spain They were submitted to a searching test on the occasion of the Investiture of the Prince of Wales at Carnarvon when they accompanied the Westmoreland and Cumberland Yeomanry which had been ordered to attend the ceremony One of the stations was established in the vicinity of Carnarvon while the other was set up at the head quarters some distance away By means of these two installations constant communication was maintained between the two points which did not possess other communicating facilities beyond a circuitous telegraph line also with the Royal yacht anchored off Holyhead and with the warships in attendance Communication was also secured between Carnarvon and Liverpool Heavy work was thrown upon the field station at Carnarvon as messages had to be received and distributed to all points



This regiment employs the two outfits regularly on maneuvers Within a few minutes of halting the company can secure communication with another mounted unit or the main camp while only a few minutes are required to dismantle the whole equipment and to pack it upon the horses' backs for transport The British War Office is following this development closely owing to its great military value, and there is every probability that similar sets will be distributed among the regular mounted troops

The equipment set up in the field.

The wireless cavalry squad with complete equipment.

Wireless equipment in use. Note the saddle carrying the generator set.

A PORTABLE MILITARY WIRELESS PLANT

Neglected Paestum

ONE of the noblest Greek cities of southern Italy was Paestum of the wild roses, and the site is of easy access A carrozzella will convey you all the way to Pesto from Sorrento or Pompeii, if you dislike railway trains Pesto itself is of course a malarial wilderness, over which three big Doric temples stand silent guard Qualified excavators have neglected the site to their shame, because these monuments and a Roman town wall seemed to survive the dead Greek city alone. Pesto is a buffalo pasturage. Piranesi's etchings of the old temples are familiar to print collectors, and one sees them painted and photographed a-plenty in the Naples art shops If our architects realized how superior they are to the over-extolled Parthenon in their rugged early Greek lines and masses, to say nothing of their glorious gray and orange weathering, they would copy their serried colonnades and their towering gables Wilkins surveyed them for his "Magna Græcia" Pesto is further the scene of a chapter in Hans Christian Andersen's fairly popular Italian novel "The Improvisatore"

In the face of all this modern notoriety, a German editor has been able to locate the ruins of Paestum or the Greek Poseidonia on the south coast of Sicily, and to credit Spinazzola with the discovery of those early Greek structures in 1911' His firm contention that the extant temples at Pesto originally occupied hilltops like other Greek temples, and that plentiful remains of the antique city lay buried between them, was the Neapolitan archeologist's real merit Spinazzola has proved his point with pick and hoe He began his probe at the two principal gates in the Roman wall Vestiges of the city's older, Greek gates were found under the Roman The next step was the location of a Greek 'Main Street" on the earlier level, along a line connecting the north and south gates An abundance of wall, gate, road-bed and house ruins, vases, terra cottas, lion head gutter spouts, bronze swords and spear heads, bracelets and brooches has rewarded the excavator's patience

Spinazzola's venture has incidentally enriched the Naples Museum's gallery of antique sculptures with a beautiful super-heroic statue of a real Roman hero, the elder Drusus The marble portrays the Augustan prince in a pontifical robe And above all, the majestic old temples of Neptune and Ceres crown the summits of their original terraced eminences again The seaboard settlement has recovered its twofold acropolis

Earth-eating in West Africa

HENRY HUBERT publishes in the *Bulletin du Comité de l'Afrique Française* an interesting account of the practice of geophagy in the French Sudan. Although the practice is common in many parts of the world, this particular case is remarkable for the systematic way in which the dirt is collected, and for the fact that it occurs in a well-cultivated region, where food is abundant The earth consumed is a clay, which is found intercalated among the grits of the region in beds of various thickness The deeper layers are preferred, and for this reason the natives dig galleries, which are so crudely constructed that falls of earth frequently occur, sometimes with fatal results When an unlucky miner is thus buried, no attempt is made to rescue him, as it is believed that the divinities of the mines require an annual victim. It is stated that individuals not infrequently consume seven and a half pounds of clay daily.

The Peking-Kalgan Railway

The First Railway Financed, Engineered and Built Solely by Chinese

By F. C. Coleman

IT is a fortunate circumstance for the Chinese in their contention for the full supervision of the expenditures of all railway loans from foreign syndicates, that the Imperial Peking-Kalgan Railway, which up to this time stands as the most difficult venture of its kind yet attempted in China, should have been financed, engineered and built solely by Chinese. Of even greater importance in support of this contention is the fact that this road has set a record for low cost of construction which, all things considered, has seldom been equalled. The Peking-Kalgan Railway runs from the capital of the Empire to the chief city on the caravan route to Russia. It is now 130 miles long and is being extended. It was built from the surplus earnings of the government-owned Imperial railways of North China, and from the first rough survey to the driving of the last spike no foreigner had anything to do with its construction. To-day its operation is entirely in the hands of the Chinese. That it was built in spite of natural obstacles to construction which foreign experts declared were absolutely prohibitive to any Chinese engineer and possibly even to themselves, is a personal triumph of no mean magnitude for the chief engineer, Jeme Tien Yow. That it was built at a cost almost without parallel for similar construction—at a lower figure per mile even than some of the foreign built roads on the level floor of the Yangtse Valley—is a striking object lesson for Europe and America, and will be a powerful weapon for the Chinese in their contention for fairer terms in borrowing foreign money. The line is now operating at a profit, so the directors of the Imperial Railways of North China have succeeded, not only in providing their government with a line that is strategically valuable, but with one that earns a return on the money invested. From first to last, the Peking-Kalgan line is a great triumph for the Chinese.

The name of Jeme Tien Yow stands out above all others in the record of the Peking-Kalgan Railway, and his achievements in connection with that enterprise alone are sufficient to have won him the undisputed title of China's leading engineer. He was one of a number of Chinese students who were sent to America about 1880 to receive university educations. Jeme Tien Yow was the only one who undertook a course in engineering. He graduated from Yale in 1888, and then went to a technical school in England for several years. On his return home he went into the employment of the Imperial Railways of North China, where, working under the British manager of that line, Mr. C. W. Kinder, he rose, post by post, outstripping many foreigners who were senior to him in point of service. Later he was appointed chief engineer of the Peking-Kalgan line.

Preliminary surveys were made for this line in the summer of 1905 and construction work was begun in October of the same year. At the end of nine months the first section of the line, 32 miles long and reaching to the mouth of the Nankow Pass, was completed. Chinese were employed in every department, from the lowest coolie or camel-driver up to the chief himself. The saving of the salaries of high-priced foreign officials, interpreters and various middle men became apparent at once. An even greater saving was found in procuring earthwork and similar constructive materials directly from petty contractors along the line, instead of giving the contract to big contractors and then paying all the commissions necessary in their system of subletting and resubletting contracts. This practice is not confined to China, but is carried to greater lengths there than anywhere else, and its abuse has been responsible for the great expense of so much work done by foreign syndicates in that country. For earthwork on this first division of the Kalgan line the average cost was about two cents per cubic yard; while after the Nankow Pass was reached and the embankments had to be made out of broken boulders, the cost rose to three cents a cubic yard. Broken stone for concrete was purchased for from 13 to 33 cents a cubic yard, delivered ready for use, and sand for the same purpose averaged about three cents. Most of this section of the line runs over a flat plain, gradually sloping to the mountains.

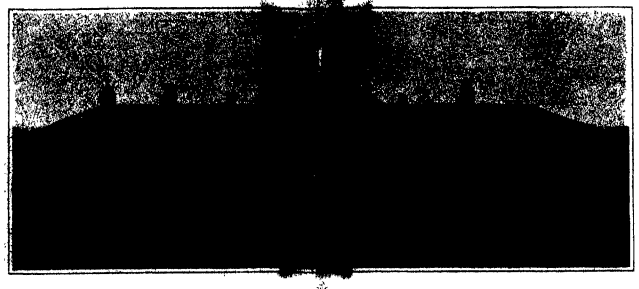
The Peking station is at Liutsin, a short distance outside the great wall of the capital, as very few Chinese railways penetrate the walls of any of the old cities, both on account of the lack of space inside and because of the violent prejudices of the conservative element of the people against such desecration. For some distance the line runs through a fertile farming country dotted with small villages. The most striking feature of this part of the journey is Waushoushan, the £10,000,000 summer palace of the old Empress Dowager, with its roofs of Imperial yellow tiles standing out strikingly against the green hillside upon which it stands. Shortly the country commences to show traces of erosive wash from the mountains, and before long the crossing of numerous cuts and "arroyos" of gravel and boulders begin. The bridges are all solidly built of steel and concrete, and the largest of them is nearly 300 feet long, having five 50-foot spans and one of 110 feet. The steel superstructure of this bridge—with the exception of the long span which was supplied from England—as well as of all the other bridges on the line, was built in the shops of a Chinese company at Shanhaikuan. The Liutsin section of the line has a total of 21 bridges and 17 drains, aggregating 1,352 linear feet of openings.

At Nankow are quarters for employees, machine shops, locomotive sheds and numerous other railway buildings of excellent construction. There is an up-to-date foundry in connection with the machine shop, where castings of any size required in locomotive and car repairing can be made. A well-equipped hotel, built and managed by the railway, fills a long-felt want of tourists. The Nankow Pass section the most difficult piece of railway engineering in China, was the next portion of the line to be built. This pass must have presented a very discouraging aspect to the Chinese engineer when, with the honor of his country at stake and with the "inevitable" failure, prophesied by all the foreign engineers in the East staring him in the face, he started over it for his tentative study. There is a rise of 1,800 feet in the 10 miles from the mouth of the pass to the summit at Pataling, and the gorge is so narrow that it seemed almost impossible in places to keep the necessary curvature without tearing down the mountain. Five distinct surveys were run, and on the earlier ones some of the curves were sharp enough to "break the back of a snake," as Mr. Jeme Tien Yow stated it. Slowly, and with infinite pains, a practicable route was determined upon, and along this the present line has been built. Even the most exhaustive surveying, however, could not solve all the problems, and at a point not far from the summit tunnel, where it was necessary to have a station and sidings, a zig-zag was introduced. However, a station being necessary, the inconvenience of the zig-zag was minimized.

The general direction of the railway up the pass is about parallel to that of the old stone-paved highway which leads down to Peking from the plains of Mongolia, the road over which all the Tartar invasions of the Chinese Empire have come since the time of Ghengis Khan. The general aspect of the country, in its rockiness and lack of heavy vegetation is strongly suggestive of some of the lower reaches of the more northerly passes of the Chilean Andes in South America. The railway up the pass is one continuous succession of cuttings, embankments, and tunnels. The embankments, regardless of their height, are for miles faced with cut and fitted granite blocks. All the overhanging boulders have been removed, or securely cemented into place even for hundreds of yards up the mountain sides, while the solid rock of the cuttings is trimmed as smoothly and evenly as if lined with plaster. The 19 bridges and the 36 culverts are all steel, concrete or cut stone, and in many instances where swift mountain torrents are crossed, cemented beds for the water prevent undermining.

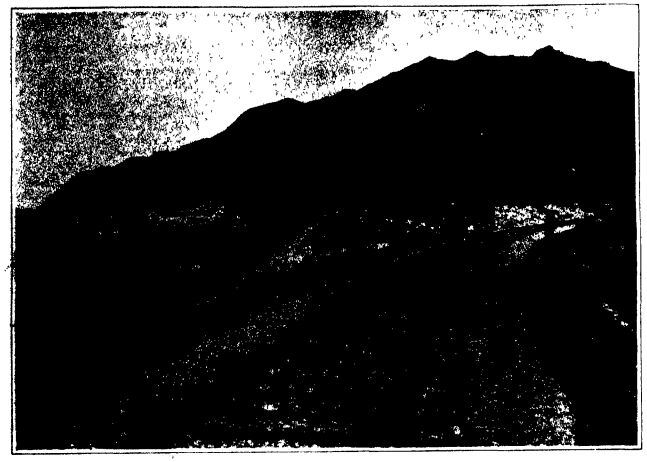
The tunnels of this division are four in number, their respective lengths, in order as approached from below, being 1,200 feet, 150 feet, 450 feet and 3,570 feet. The first tunnel which was driven through limestone, was completed in about six months. The other three tunnels, all of which are in granite, were completed in good time. The one at the summit, the longest in China, took over a year. The summit tunnel, which runs under the Great Wall, was driven according to thoroughly up-to-date practice. A shaft was sunk near the half way point, and with the aid of fans, drilling machines and modern hoisting apparatus, work was carried on in both directions from the center, as well as from the ends of the tunnel. This shaft, with another, which was sunk to admit air near the northern portal of the tunnel, have since been lined with stone and retained as permanent ventilators. All the tunnels are lined throughout with concrete, which is also used for the portals. The open cutting in the pass, half of which is in solid rock, amounted to 640,000 cubic yards, while the embankments required an aggregate of 1,275,000 cubic yards of material. The latter, except such as was provided from the cuttings was obtained cheaply by blasting it out of the mountains close by. This earthwork labor cost only £44,000.

The third or Chatao-Kinmingyh division, 38 miles long, was of comparatively easy construction. There are 17 bridges and 32 drains in all 2,062 feet of linear openings. The principal engineering feature is a 1,000 foot bridge having ten 100-foot spans at Huilahsun. The fourth or Kinmingyh-Kalgan division is also 38 miles long, and in engineering difficulties rivals that of Nankow Pass. At Halangshupo 16,500 feet of granite and sandstone have been cut through to make a way for the line along the steep bank of the Yangho, the cutting varying from 10 feet to 85 feet deep. There are 2,075 linear feet of openings, 21 bridges and 130 drains. The coal in use is from a mine worked by the railway company near Haiahua, and the present output of 400 tons per day is ample for the railway requirements. There is a branch line 16 miles in length leading from Hsichihmen to the Mentoukou coal fields, which gives the product of these mines an outlet to the Peking market.

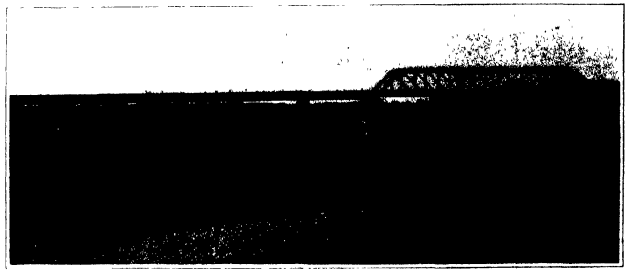


Of the character of the roadbed of this thoroughly built line the photographs give a very good idea. (See pages 401, 410, and 411.) The sleepers are mainly of Japanese hard wood of a class which would cost in the vicinity of a dollar in the United States, but which are laid down in China for less than half that figure. On the mountain divisions creosoted sleepers are used, with safeguards to prevent rail creeping. For the main line, which is of standard gage, 85-pound rails are used, for sidings and branches 60-pound rails.

The locomotives for the mountain divisions of the line are mostly "Mallet" articulated compound, as shown in two of the photographs, and they were built by the North British Locomotive Company (Limited) of Glasgow. Such of the passenger cars as have not come from the shops of the Imperial Railways of North China at Tongshan are of American manufacture, but the company will doubtless build all its own cars in future. The China-made cars are of a modified British type, a sort of a compromise between a side-door compartment car and one of the center aisle-type. The freight cars are of 30-ton capacity, and were mostly built by the Leeds Forge Co. (Limited).



The Chinese Students' Journal makes this strong plea for Chinese control of expenditures in railway construction: "A railway line is not a clubhouse or a private mansion upon which the owner or owners may expend millions merely for the gratification of their sense of beauty or for an exhibition of their wealth, but it is a commercial investment. The amount of capital invested in it must be commensurate with its power of paying dividends, and in the case of Chinese railways the redemption of the bonds must not be for a moment forgotten. Economy on the Peking-Kalgan railway has been reduced almost to a science. There is no temptation to spend money recklessly, as no five per cent commission on every tael spent can enrich the coffers of any corporation. There are no engineers who must have foreign style residences, cement tennis courts, pneumaking machines, palatial house boats, and princely salaries before beginning work. There are no interpreters to browbeat the contractors to make trouble with the local officials, and to make a fortune in little or no time. All contractors deal with the engineers directly and no graft exists. The figures for the price of materials explain in a large part why a railway built under our own supervision and by our own engineers is so very much more economical. Another very important advantage gained is the peaceful condition of the coolies during construction, due to the absence of misunderstanding between engineers, the coolies and the country people. No disturbance of any kind, still less of any rioting, has ever happened and the work has proceeded so smoothly and quietly that the local officials are never called on to suppress disorders or punish offenders. There can be no unpleasantness arising through the interfering of foreign consuls and the referring of insignificant incidents to the minister in Peking. One and all understand that the railway is a Chinese railway, that our own money is being spent that the coolies are our own people though they are coolies, that the officials are officials appointed by the Emperor, and the result is that the work proceeds without a hitch of any kind."



An example of heavy cut-and-fill work.

Some Suggestions for Home Experiment

Microscopic Photography

By Norman Borden

IT is the purpose of this article to give a definite idea of how photomicrographs are made and at the same time to give the possessor of a microscope precise and accurate directions for obtaining photographs of microscopic objects.

The entire apparatus consists of a microscope and accessories, camera, shutter and body, rack for carrying the camera and if necessary a source of artificial light. Fig. 1 shows most of the pieces of apparatus which are to be considered separately in the following paragraphs.

First the quality of the objectives must be taken into consideration. A chromatic objective is entirely out of the question for making high amplifications. An achromatic objective free from scratches, must be used in securing high power negatives. Objectives of 3, 4 and 16 millimeters focal lengths will be found to suffice for amplifications up to 1,000 diameters. Also if the eyepiece is to be used in connection with the objective, both lenses must be perfectly clean. One method of cleaning lenses is to wash them in a solution of tincture of green soap and distilled water, using absorbent cotton, and, then, as a final, to rinse them in pure grain alcohol.

One form of a frame work for carrying the camera is shown in Fig. 1. The base *B* is large enough to accommodate a stereopticon or other source of light. The uprights *A*, of which there are two, should be made of metal rods or tubes. They must be fastened rigidly to the base and if necessary strongly braced. It is of great importance to have the apparatus as rigid as possible so that it will not vibrate. Four feet is a suitable length for the uprights. In constructing the camera and bellows, the main object is *to get them light tight*. For the bellows rubberized cloth will be sufficient. The plate holder is made to slide upon the uprights and is provided with thumb set screws so that it may be fastened at any position. If a regular camera shutter is not at hand the exposing can be done by using a cardboard before the mirror of the microscope.

Perfectly white light gives the best results. Sun light may be used if the photographer is provided with a heliostat. The student had better resort to an artificial light such as gas or electric light. The tungsten light is the best of the convenient incandescent lamps. If this lamp be used as shown in Fig. 1, its light will be found sufficient for all magnifications up to 1,000 diameters. If the gas mantle is used the stereopticon should be provided with a number of light trapped ventilators. Monochromatic light can also be used to advantage with certain objects. This kind of light is obtained by the use of ray filters which absorb all the light except the color wanted. A substitute for true monochromatic light is the light which passes through a cell containing ammonio-sulphate solution. This last named light is also free from heat waves so that there is no danger of softening the mounting media while making long exposures. Fig. 2 shows how such a cell may be made. There are times, too, when dark ground illumination will be wanted. This is effected by stopping out the light immediately behind the object with some opaque substance put on the front lens of the condenser. When done properly, a cone of oblique rays illuminates the object and gives it more relief so that it has a natural appearance.

The appearance of the object in the negative has to do with the plate used. Isochromatic plates give truer color values than the ordinary plates. Fast plates can be used to an advantage over the slower ones.

Working Directions.

We will begin by picking out an object that is suited for photography, namely, a diatom "Triceratium Favus," which is generally the first one of prepared diatom plates. The diatom is placed in the center of the field and then the microscope is put in connection with the camera by means of a small rubberized tube. The magnification will be about 200 diameters, so the camera is fastened in its position and a rough focus is made. The finer details cannot be seen on the ordinary ground glass, so a focusing glass is used and a piece of plain glass is substituted for the ground glass. In this last named method of focusing the actual image is used to focus upon and it must be in the same plane that the sensitive surface of the plate will be. The light is adjusted while focusing, by means of the iris diaphragm.

Rules for exposing cannot be given in precise statements. With a heliostat, 5 millimeters objective and 400 diameters amplification, the exposure would have to be about 2 or 3 seconds. Using light from the clear blue sky, an exposure of 30 to 90 seconds would be made for an amplification of 50 to 75 diameters. The *time of exposure depends* upon the light used, the *color* of the object, the plates used and the magnification. The one aim in making photomicrographs is to produce a dense negative with contrast.

Developing and Fixing.

As there are a great number of reliable developers on the market it is not advisable for the beginner to mix his own. Develop the plate until the details show from the back of the plate and then rinse in plenty of water and transfer to the fixing bath. Here it should remain long enough to clear the last traces of silver. The negative is then washed and intensified if necessary. To intensify, immerse the plate in a saturated solution of mercury bichloride until it is bleached white and wash thoroughly. Next immerse in a solution of ammonium hydroxide (about 10 per cent) until the film turns black again. This method produces intensification to a moderate degree.

Preparation of Specimens.

Epithelial cells are good objects for practising mounting and staining. They are found in a free condition in the saliva, the microscopic constituents of which are (*a*) the salivary corpuscles, which are about the size of the white corpuscles of the blood (8 to 10μ); (*b*) the pavement epithelial cells; (*c*) living organisms from the cavities of the teeth; (*d*) leptothrix buccalis, which are large rod-shaped bacteria. All these objects are well suited for photography when deeply stained with fuchine and mounted in balsam. Fig. 3 shows an epithelial cell with bacteria.

In Fig. 4 is seen a group of micrococci, which were cultured on a slice of potato. They are easily stained mythel-violet and mounted in Canada balsam. The spores of the fungus, Aspergillus Glaucus, magnified 500 diameters are seen in Fig. 5. Fungus spores do not need be stained and are best photographed dry. Among other objects are pollen grains, sections of plant stems and plant hairs. The stagnant water in frog ponds contains innumerable specimens.

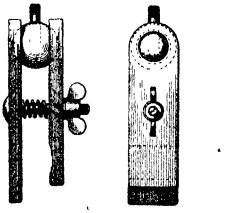
A Heat-storing Water Bag



THE bag described in the following paragraphs is a great improvement over the ordinary hot water bag. Besides its property of retaining heat longer, it can be prepared so that it will store heat, be set aside and then used at a future time. It is then ready for any emergency. Fill an ordinary hot water bag with either sodium sulphate crystals or hypo crystals. The crystals cost about ten cents per pound at the drug store. Sodium sulphate is preferable. To use, place the bag, which should be tightly corked, into a vessel of boiling water, and boil for about fifteen minutes. The crystals in the bag are now in a liquid state, i. e., a super-saturated solution has been formed. The bag is now ready for immediate use. It will now impart its heat steadily about four times as long as the same weight of water. If the bag becomes cold in too short a time, it is a sign that it has been boiled too long.

To prepare the bag for future use, boil twice as long as you did for immediate use. You can if you wish, use the bag while it is giving off its temporary heat in cooling, and then later utilize its latent heat. The storing qualities of the bag depend upon the heat of crystallization. The solution in the bag has become super-saturated by long boiling of the bag. Upon cooling it remains a liquid, but if it is touched by the cold fingers or suddenly jarred, or if one of its crystals is inserted in the solution, the whole mass crystallizes, and the heat of crystallization is given off. Sometimes the solution on solidifying forms in one hard lump. This does no particular harm, but it may be prevented by kneading the bag at intervals while in use.

Ball Clamp for Holding a Camera

By J. H. Bentley

A BALL clamp for holding a camera to any suitable support may be made very simply as follows: Two clamp plates should be fashioned out of a 1¼-inch by 5/16-inch stick of wood, one being 4¾ inches long and the other 4¼ inches. A ⅜ inch hole is drilled at one end and countersunk on the inside, the other end

A camera-supporting clamp.

of the short one being cut away as shown to give the clamp a good grip on angles. Very often a wooden ball can be found on the end of broom handles or a discarded child's ten-pin set, knobs, etc. The stud in the ball is ¼-inch-24 thread, for standard cameras, and is pressed tight into a hole drilled for it.

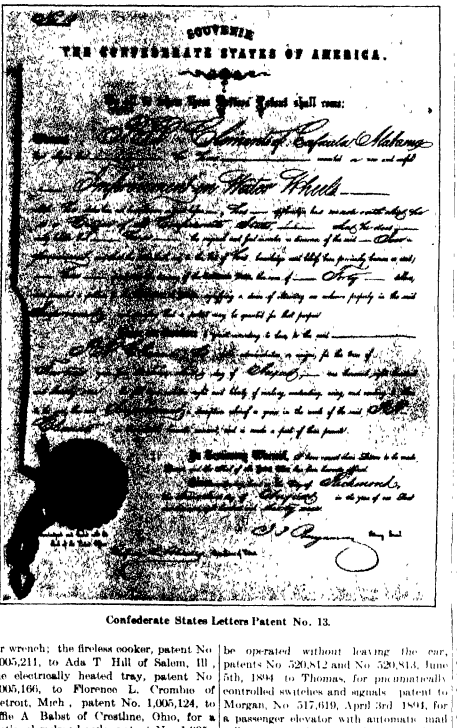
The cup-head bolt is also ¼-inch-24 and the inside of the head should be filed a very obtuse V as shown to prevent turning and to form a rocking fulcrum when on an angle. The spring on it keeps the clamps apart.

The Inventor's Department

Simple Patent Law; Patent Office News; Inventions New and Interesting

A Confederate Patent Discovered

ON the 23rd day of August, 1861, the Confederate States of America granted Letters Patent, No. 13, to P. R. Clements of Eufaula, Ala., covering an improvement in water wheels. The original of this patent, which is in the possession of a Washington patent attorney, is the only one known to the United States Patent Office to be at present in existence. Its whereabouts was discovered by Mr. James T. Allen, a first assistant examiner in the office, and one of the oldest employees in point of service, now in that bureau. Mr. Allen entered the Patent Office in September, 1868, several years after the Confederate States of America ceased to exist, but he has always been interested in the collection of statistics and information regarding the work of American inventors.



Mr. Allen obtained the loan of Confederate Patent, No. 13, and at his own expense had a plate made, from which the reproduction on this page is taken. There are several interesting features about this patent. It will be noticed that the term of the patent is fourteen years, whereas at that time United States patents were granted for a term of seventeen years, the period having been extended from fourteen to seventeen years by the Act of March 13th, 1861, nearly six months prior to the date of the Clements Confederate patent. The fee is fixed at forty dollars, which is very reasonable, considering the fact that the present fee for a United States patent is thirty-five dollars. Confederate money is not specified in the grant, but it is to be presumed that that currency was the proper legal tender in the Confederate Patent Office. The grant bears the signatures of J. P. Benjamin, the first Confederate Attorney General, and of Rufus R. Rhodes, Confederate Commissioner of Patents.

There is room for conjecture in the serial number of the patent, data as to the previously granted patents, a round dozen in number, are not available. The patentees under these may long ago have faded into dust, the inventions may be as worthless as the grant under which they were issued. Whether or not thirteen was the sum total of patents issued by the Confederate States is not known. Perhaps in the possession of some old family of the South are the original records of the long-forgotten Patent Office of the Confederacy. These alone can answer the question. Perhaps, carefully guarded as priceless mementoes of the past, are scattered here and there throughout the land of Dixie the yellowing documents granting exclusive rights to inventions long since forgotten or superceded.

The pages of history are always being reopened in this way. Looking down the long vista of years, one can see the struggling states south of the Mason and Dixon line, who believed in the right as they saw it, and sacrificed their all to support their convictions. When P. R. Clements of Eufaula, Ala., was handed Letters Patent, No. 13, of the Confederate States of America, the paper was clean and crackling and the signatures on it were scarcely dry. High hopes bounded in his bosom as he realised that for fourteen years he would have protection in which to enjoy the fruits of his toil. Even now his improved water wheels may be turning in some hamlet of the Southland, grinding the meal that is to form the daily bread of its citizens—citizens of the Confederacy no more, but citizens of the United States, the nation that has recently issued its millionth patent. But the holder of that millionth patent, which has been so widely advertised and so lauded as being typical of the great achievements of the American brain, was not more proud of his possession than P. R. Clements of Eufaula, Ala., when he was granted No. 13, of the Confederacy.

Women Patentees in One Issue

AS showing the activity of the ladies along inventive lines, it may be noted that among the patents issued October 10th, 1911, are found many to women inventors. These include Ada Lutton of Revere, Mass., who patents, No. 1,005,244, a ribbon renovating device, Evalena O. Leggett of Niagara Falls, N. Y., whose patent, No. 1,005,240, is for an insulating compound; patent No. 1,005,213, to Hattie D. Hinds of Rutland, Vt., for a jar wrench; the fireless cooker, patent No. 1,005,211, to Ada T. Hill of Salem, Ill., the electrically heated tray, patent No. 1,005,166, to Florence L. Crombie of Detroit, Mich., patent No. 1,005,124, to Effie A. Babst of Crestline, Ohio, for a sectional railroad rail; patent No. 1,005,542, to Ada Harmer of St. Louis, Mo., for a stand and gage for dress makers, patent No. 1,005,575, to Estelle C. Raney and Charles E. Simmons of Steubenville, Ohio, for an automatic circuit breaker for electrical distribution systems; Mary E. Van Luven, Oakland, Cal., No. 1,005,675, for an irrigating vessel; No. 1,005,752, to Jennie R. Sherrod of San Francisco, Cal., for a hook for hooks and eyes.

Confederate States Letters Patent No. 13.

Patents That Expire This Year

AMONG the many patents for important or representative inventions which have or will expire during the year 1911 may be mentioned the patent to Smethurst, No. 520,902, June 5th, 1894, for potato harvester; the seed drill patent, to Schopp & Liese, No. 513,060, January 16th, 1894, patents to Pitt, No. 516,745, March 20th, 1894, and to Stevens & Swart, No. 519,460, May 8th, 1894, for transplanters, the patent, No. 521,629, to Popp, August 14th, 1894, for preserving the sugar making machine of Moondes, No. 514,238, February 6th, 1894, patent No. 522,132, June 26th, 1894, to Van Ruymbeke, for distilling glycerine, patent No. 528,322, to Castner, October 30th, 1894, and to Crapney, No. 520,257, May 22nd, 1894, for the electrolytic production of caustic soda, sodium carbonate and chlorin, the patent to Coyle, No. 518,394, April 17th, 1894, for sewer construction, No. 522,782, to Clouser, for a railway switch which can be operated without leaving the car, patents No. 520,812 and No. 520,814, June 5th, 1894, to Thomas, for pneumatically controlled switches and signals, patent to Morgan, No. 517,619, April 3rd, 1894, for a passenger elevator with automatic mail collecting and delivering devices, Sellers, No. 520,940, June 5th, 1894, for armature winding, patents to Scott, June 5th, 1894, No. 521,051, and to Hunting, February 20th, 1894, for electric motive power; Fiske, No. 529,484, November 20th, 1894, for printing telegraph, the Copeland patent, No. 520,110, November 13th, 1894, for bicycle crank shaft fastening, dispensing with the connecting keys. Greater strength as against telescoping or crushing in collisions and other accidents is sought by a rolled steel plate construction in a patent, No. 512,960, of January 16th, 1894, to Jewett. Miller's patent, No. 516,084, March 6th, 1894, for cable transportation, patents No. 516,053, March 6th, 1894, to Hulett, and No. 527,117, No. 527,118 and No. 527,119, to Lay, October 9th, 1894, for coaling steamers, No. 518,895 of April 24th, 1894, to Porter, for handling hay, and No. 515,200 of February 20th, 1894, No. 526,849, of October 2nd, 1894, and No. 530,232, of December 4th, 1894, to Loudon, for means for unloading hay, the Burgess patent, No. 520,772, of May 29th, 1894, for automatic fire arms, the hot water car heating patent to Towne, No. 512,239, of January 2nd, 1894, patent to Bicknel, No. 526,364, September 18th, 1894, for a brushing machine, the shoe insole channeling machine, patent to French and Meyer, No. 529,900 of November 27th, 1894, the stitch separating and welt indenting machine, patent of Hadaway, No. 521,978, of June 26th, 1894, the patent, No. 528,128, of October 23rd, 1894, to Julian, for sole-rounding machine, patent to Dunbar, No. 521,243, June 12th, 1894, for machine for making screws, bolts, etc., Klatte patent, No. 523,432, July 24th, 1894, for chain making machine, the Coffin patent No. 512,094 of January 9th, 1894, and the Hunter patent No. 520,960, May 22nd, 1894, for electrical welding of metal, patent No. 511,705, February 14th, 1894, to Cornell, for label affixing machine, patents to Barry, January 2nd, 1894, No. 511,745, and to Ethridge, No. 521,005, June 19th, 1894, for mail marking machines, the Goodson patent, No. 530,181, December 4th, 1894, for typesetting machine, the Northrop loom patent No. 529,943, November 27th, 1894, patent No. 517,705, April 3rd, 1894, to Morgan, for machine for dovetailing box blanks, clothes pin making machine, No. 513,572, to Hall, January 30th, 1894, tooth pick machine, No. 521,734 and No. 521,739, June 19th, 1894, Seamman, No. 515,506, February 27th, 1894, to Sherman, for floor-board boring machine, automatic screw driving device to Briggs, No. 529,701, November 27th, 1894, No. 526,068, to Davis, September 25th, 1894, for rotary machine, the photograph burnisher to Bolles, No. 527,-315, October 9th, 1894, and magazine camera No. 522,924 to Spooner, July 10th 1894, illuminating life preserver to Guest and Bates, No. 512,057, January 16th 1894, apparatus for oiling waves, Hallett, No. 529,479, November 20th, 1894, marine torpedoes, Holland No. 522,177, June 26th 1894, and Baker No. 530,866, December 4th 1894, Gorham, No. 527,-952, invalid lad.

Inventors' Permanent Exhibit in London

CONSUL-GENERAL JOHN E. GRIFFITHS, in an official communication published by the Bureau of Manufactures is quoted as saying:

"It is stated that a permanent exhibition will be held in London for the benefit of inventors. The exhibition is to be kept open throughout the entire year and inventors will be afforded the opportunity of displaying their patents to possible purchasers not only in the United Kingdom, but from all parts of the world. It is purposed employing expert demonstrators, who will take visitors through the various sections of the exhibition and who will have technical knowledge of the sections with which they are specifically connected.

"Through this exhibition which has a financial side it is hoped to bring inventors who are anxious for promising patent in which they may place their money in touch with patentees who not have something of real value to offer but who are unable frequently, under existing conditions, profitably to dispose of their inventions."

Invention Necessary to Patentability

WE are constantly coming new things that seem ingenious and many times important, but which cannot be protected by patent because they do not possess or

involve the prime essential to patentability invention A thing may be new and it may be a useful purpose, but if it stops there and does not involve invention, it cannot be protected by patent, because patents are the reward for the products of invention Jim Walker says "Patents are given for things invented, and not for doing otherwise produced" He also announces the absence of any universal affirmative rule for determining whether invention exists, but gives a number of negative rules, thus emphasizing the difficulty of determining what is or is not invention but in no way affecting the fundamental principle that invention is necessary to patentability, thus dignifying and elevating the patent grant Many inventors have not the mechanical skill to produce the invention in physical form and it is not necessary that they should have it for it the inventor conceives and supplies all the inventive ideas he can employ mechanical assistants in the production of the actual embodiment of his invention

Notes for Inventors

A Sensible Night Signal for Automobiles.

—Many of the most serious automobile accidents are due to a misunderstanding or ignorance of the driver's intentions, and so a system of hand signaling has come into vogue, which, although crude, answers many purposes so long as the driver of one car is enabled to see that of another At night such communication between the car operators is impossible A real signal has been devised for the purpose It is electrically operated and consists of three lamps and a horn A red lamp is fit permanently while above is a green lamp, which, being flashed, signifies that the driver is about to stop To the right and left are white lamps, signifying his intention to turn to the right or left These signals are all electric and are operated by buttons, conveniently placed for operation by the chauffeur As any one of these signals is made, the horn is sounded to attract the attention of anyone who may be following

An Illuminated Life Preserver.—An illuminated life saver has been on trial for some time in the German navy and so highly is it regarded that it is likely to be adopted for use on the warships It consists of two long floating cushions, which are secured on the chest and back, passing over the shoulders, and which are strapped in place somewhat after the fashion of a knapsack This shape is said to support the body in the water much more comfortably than the life preservers of older form This apparatus is equipped with an electrical lamp, supplied with current from a battery, and the lamp is automatically thrown into action upon the buckling of the belt around the person This feature is regarded as of great value in some kinds of accident, especially those at night, and in times of peace, although in warfare it would not always be desirable

Street-car Letter Boxes It was objected to early letter boxes for use on street cars for the collection of mail matter, that where the openings were of sufficient size to permit the deposit of mail conveniently, they also permitted the entrance of rain, which generally had a serious effect, causing the envelopes to become unsealed and address es effaced or at least rendered illegible The postal authorities are conducting some experiments at Washington with a street car equipped with a letter collecting box which is proof against the entrance of rain The box has a large opening with sloping sides which facilitate the passage of mail matter without regard to size or number of pieces deposited The sides of the opening are supplied with a double arrangement of gutters which catch all raindrops and carry the water away from the mail matter in the box

The Humors of Patent Specifications

The ideas of different people as to the usefulness of a device necessary to support a patent are sometimes very amusing A patent was once granted for a cube-shaped device, intended for use by card players, as a tally block, and in the original specification, the inventor, either from a sense of humor or from a misunderstanding of what was required in applications for patent, described some remarkable utilities for the device Thus he writes.

"Besides the above mentioned conveniences to a card player, I claim it to become a constant companion to present humanity and countless millions to come The man of business will carry it in his coat pocket and rejoice to be in a position to meet any emergency A hole in his pocket does not bother him as he can carry his loose change in the tally block The sponge can be changed at will containing the perfume that shall permeate his clothes, walking about on the street his nose is apt to offer a good landing place for soot, the little mirror on tally block keeps him from rubbing at it xxxed and spitting on his handkerchief, the sponge will perform that duty No fear of foot pads as a corner of the tally block on the top of his head with a gentle pressure will make quite an impression Coming home baby cutting teeth and is cross will change into a smiling miracle when papa pulls out the tally block and juggles with the dice box, its attention being riveted the pain is all gone Coming late from a lodge meeting and the key being about one inch out of his reach on the transom, the tally block is as good as a step ladder In case wifey thinks she has heard a noise in the cellar or wants him to look at the gas meter, the tally block answers the purpose of a candle holder To a poet with inspirations or those who wish to keep record of a dream and write in the dark, nothing takes the place of the tally block"

and so on for many paragraphs of the same kind of matter, which, needless to say, were eliminated before the actual issue of the patent

There are Cops and "Cops"—The examining corps of the Patent Office is of an unusually high order of intelligence and the members are generally acquainted with the various arts Sometimes amusing things occur when an examiner fails to understand a technical term well known in another art A "cop" is defined as "the conical roll of thread formed on the spindle of a spinning machine" In an application, now issued, and consequently a public record, the applicant referred to an illustration as "the representation of a cop" Not understanding the word, the examiner wrote, seriously, a letter in part as follows

"The attention of the examiner being called to this case, he regrets it as in no condition for official judgment on the merits Applicant shows a device which the examiner would be inclined to regard as the familiar method of a ball of twine Applicant says however it is 'the representation of a cop' It does not look like a policeman, which to the examiner's mind is the popular signification of the word cop, and consequently the word requires some limitations"

The Inventive Convict.—That all people, even hard-hearted jailers, are interested in inventors and inventions is shown by the following story Some years ago a Washington patent attorney was called on by a man from the West who had an improvement in some refrigerating apparatus and prepared and filed the application for patent, the inventor leaving ostensibly for home A few days later the attorney received a telegram from the sheriff of the inventor's home county, asking whether he was in Washington, and replied that he had been but had left for home, and later received from the sheriff an explanatory letter to the effect that the inventor had been committed to jail for some offense and while in the sheriff's custody had developed the invention in which the sheriff had taken an interest, that he had, on his own responsibility, released the prisoner temporarily, so he could go to Washington to secure the patent and then return to serve the balance of his term So far as known, the sheriff is still waiting his return

Sectional Book Cases.—An early instance of a construction capable of being utilized in a sectional book-case is shown in the expired patent to Spruce, No. 224,486, patented February 10th, 1880 While specified as a post-office box, the patentee described each box as a complete and independent structure in itself, so that in arranging a number of boxes together, this single complete structure enables the placing of them in series vertically and horizontally, according to the space required to be filled, and that the boxes may be made and held in stock, from which orders may be at once filled for a number of boxes, without regard to the space to be filled by the boxes.

A Japanese Appreciation.—A government publication tells how the Japanese government, in proceeding to establish a patent system under their patent act of March 1st, 1899, sent, as a special commissioner, Mr Korekiyo Takahashi, to the United States to examine into our patent system At that time, Mr. Perry B. Pierce, now deceased, was examiner of designs, and Mr Takahashi had many interviews with him. In one of these, Mr. Pierce asked the Japanese commissioner why the people of Japan desired a patent system, and Mr Takahashi replied: "You know it is only since Commodore Perry, in 1854, opened the ports of Japan to foreign commerce that the Japanese have been trying to become a great nation, like other nations of the earth, and we have looked about us to see what nations are the greatest, so that we could be like them, and we said 'There is the United States, not much more than a hundred years old, and America was discovered by Columbus, yet four hundred years ago,' and we said 'What is it that makes the United States such a great nation?' And we investigated and we found it was patents, and we will have patents." In repeating the interview, Examiner Pierce declared that. "Not in all history is there an instance of such unbiased testimony to the value and worth of the patent system, as practised in the United States"

A Patent Office Rival of Tom Sawyer's.—A story is told of the chief clerk of the United States Patent Office, Mr William F Woolard, which is in the class with Mark Twain's famous account of how Tom Sawyer escaped the irksome task of whitewashing a high board fence, by persuading his playmates that such work really was a rare pleasure in which an ordinary boy had no opportunity to indulge. In his boyhood days the chief clerk lived in Fairfield, Ill., and it was his duty on Saturday to cut the wood for household use during the week The burdensome task was increased by having to carry the wood to the wood-house, fifty yards away. To relieve himself of that burden, young Woolard erected an inclined track and constructed a small flat car, so that no labor was involved in sending the loaded car down or the empty car up the track. Its availability as a gravity railway for pleasure riding was soon discovered, and when the boys of the town began to so use it, while the builder was industriously engaged at the wood-pile, a halt was called Each boy was required to cut a carload of wood in order to be entitled to a free ride. On Saturdays there was a procession of boys with axes and saws, and the wood-yard looked like a husking bee, with the result that the wood-house was soon filled to overflowing When this condition was reached, the elder Woolard would not meet the further demand for more cord wood

Snow Melting Apparatus.—A snow melting apparatus in which the snow in finely separated particles is passed into a melting chamber and heat is applied to the snow particles while finely separated is presented in a patent (No. 1,004,113) to Garry B Van Wye of New York city.

Milk and Cream Mixing Can. -To prevent most of the cream from passing off with the first milk poured out of the can, Newton Sherman has patented (No.1,004,-919) a milk can with a cover and with a milk and cream mixing device which is independent of the cover and can be operated from the outside of the can without removing the cover.

Disinfects Book Leaves.—As described in a patent (No 1,005,080) Thomas H. Hood of Greenville, Miss., disinfects books by spreading or opening the leaves by a current of air and utilizing the same current of air to deliver a disinfecting substance to the leaves.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

HAT.—H. BENSEL, 520 Fifth Avenue, New York, N. Y. This invention is an improvement in women's hats, and has in view a binding at the edge of the brim which will securely connect the inner and outer facings of the hat together and keep the lining and covering, if such should be provided, well stretched out, and give this part of the hat a finished appearance.

Electrical Devices.

INSULATING COMPOUND.—EVALENA O. LEGGETT, 1630 Michigan Avenue, Niagara Falls, N. Y This compound is more especially adapted to the insulating of electric wires or cables. It will act as a perfect insulator, and will be unaffected by ordinary variations of temperature. It can be applied after the manner of paint, which will dry quickly and will not crack or clip off. It is also a waterproof compound which will not "sweat."

APPARATUS FOR EXPLODING MINE CHARGES.—J. KRANNICHFELDT, (Schuis-Agent) Cologne, Germany. Former intermediate switches were driven by clockwork, so that in exploding all the charges in a mine one is bound to the time of the clockwork. To overcome this drawback and to enable the charges to be exploded at desired intervals—if necessary only after examining each circuit—the intermediate or local switch, according to this invention, is controlled, adjusted or operated by electric means from a distant and therefore safe central station.

ELECTRIC PUSH BUTTON—J. L. MORRELL, 15 Audubon Avenue, New York, N. Y. This invention provides a resilient rest for the plug employed in push buttons which forms an even support therefor to avoid the rocking of the button when depressed to complete the electric circuit in which it is incorporated, provides contacting members for completing the circuit arranged to avoid the carbonizing thereof, extends the supporting base of the resilient member of the button, and reduces the labor of assembling the button.

Of Interest to Farmers.

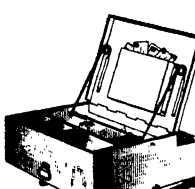
MACHINE FOR PICKING FEATHERS FROM FOWLS—C. W SMITH, care of Swift & Co., Produce Dept., Fort Worth, Texas An object of the inventor is to provide a machine for picking feathers which will effectively accomplish the operation without injury to skin of the fowl A further object is to provide a device by means of which the feathers may be removed in a much less time than in the ordinary manual operation

SWEEP RAKE—E. B ROCK, Route No 3 Studley, Kan In the present patent the invention has reference to an improvement in rakes of that class which are known as sweep-rakes or drag-rakes and which are provided with long gathering teeth that project in front barker removes bark from logs which are to wheels

HAY STACKER—E B ROCK, Route No 3 Studley, Kan In gathering hay in the field and conveying it to the stack, large wheeled rakes commonly known as sweep-rakes are employed As the stack grows in height, the difficulty of delivering the hay thereon increases correspondingly, and, to facilitate the operation, portable frames, called hay-stackers, are frequently brought into use The invention is an improvement in this line.

SCOOP FOR EMPTYING PANS—R. J ROSS, care of L C Corey, Harbison-Walker Refractories Co., Portsmouth, Ohio. This improvement provides a shovel or plow which is mounted to rotate on a shaft disposed over the pan so that it may be rotated into or out of operative position, a lever being pivoted to the plow and being adapted to engage a ratchet in a sector member for holding the plow in a predetermined position.

Of General Interest.



DISPENSING APPARATUS—L. K LARRISON, Wharton, N. J. This invention refers to a device whereby a predetermined amount of liquid can be dispensed from a bottle or other receptacle An object is to provide a receptacle with an internal receptacle or conduit adapted to receive any predetermined amount of liquid from the first-mentioned receptacle, to remove the same from the said receptacle.

COLLAPSIBLE TUBE.—C. H STUART, Newark, N. Y. In the neck of the tube is a valve by which the discharge of the paste or liquid from the tube is readily controlled, the valve embodying a piston extending crosswise of the neck of the tube and having a discharge passage in its length movable into register with the discharge passage of the neck, the valve having enlargements at each end, one exteriorly arranged and constituting an operating member by which the valve is revolved, and the other preventing the valve from being drawn from the neck.

BANDED BARKER.—I. RICHARDS, care of F. A. LONG, An Sable Forks, N. Y. This barker removes bark from logs which are to

ends up into paper pulp, and the invention particularly relates to reinforcements, in the nature of bands for strengthening and lengthening the life of the barker. The barker comprises a plurality of members, spaced apart one from the other and secured to heads with bands encircling the same throughout the majority of the circumference, thereby increasing the strength, rigidity and durability of the structure.

RURAL LETTER CARRIER'S ALL METAL CABINET.—WILLIAM T. SWIRE, Tannelton, Ind. This invention is an improvement in rural letter carriers' all metal cabinets, and is shown in perspective in open position in the illustration. The mail box is shown as separated into a plurality of compartments by a transverse partition and by partitions at right angles. A rod holds the box in horizontal position and the toggle levers are of such length that they are aligned when the box is in this position. The arms act in the manner and, in fact, are springs to lift the lid or cover. The pocket is designed for letters, while the compartments are for papers and packages. In normal position the box is supported on a dash board and floor of the carrier's wagon. The box is preferably of galvanized material and may be of any desired size.

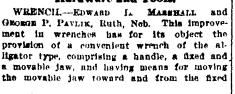
RURAL LETTER CARRIER'S ALL METAL CABINET

MANUFACTURE OF SCREENS FOR USE IN COLOR PHOTOGRAPHY.—L. DU HAURON and R. DE BERCEGOL, 17 Avenue Pauline, Joinville-le-Pont, Seine, France. The object to be obtained is to cover a transparent or translucent surface, such as glass, celluloid, paper, etc., with an extremely large number of exceedingly small regular figures, e. g., bands, rectangles, lozenge-shaped figures, etc., having three distinct colors placed close together without any interval, and each of which theoretically should, altogether, cover a third of the surface.

CLEANER FOR CHALK ERASERS.—J. A. JOHNS, 321 W 10th Street, Anderson, Ind. In this instance the invention is an improved apparatus for use in removing chalk dust from blackboard erasers, and in which the inventor employs with it rough and fine pencil-sharpeners which are operated by the same shaft and the same motor as the chalk-eraser.

FOLDING SCAFFOLD.—E. ZANN, Rhodesia Park, Norwalk, Conn. This invention has reference to folding scaffolds for general use, his more particular purpose being the provision of a simple, strong and efficient scaffold suitable upon the exterior faces of building walls and adapted to be set out and drawn in through windows and the like.

SUCTION APPARATUS.—A. SAUER, care of Sauer Power Generating Company, 5115 Rosetto Street, Pittsburgh, Pa. This invention provides a suction or vacuum apparatus, for heating, ventilating, refrigerating and other purposes. Use is made of a suction chamber provided with an annular passage connected with a steam supply and from which lead a number of spiral passages into the suction chamber to produce a vortex blast in the suction chamber.



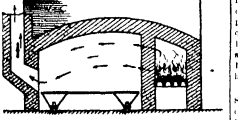
LENS MOUNTING.—G. LOWENSTEIN, 668 Park Place, Brooklyn, N. Y. This invention relates more particularly to mountings, in connection with spectacles and eyeglasses, the special purpose being to produce a device in which the lens is readily detachable from the framework normally supporting it, and yet when held in position by the framework the lens is secured with a proper degree of firmness.

WRITING POSITION AND MOTION TRAINING CARD.—J. L. MONTGOMERY, 259 Rich Avenue, Mount Vernon, N. Y. This improvement provides a card named with openings or stencil forms arranged to control the movement of an inscribing pencil; and to form a paper guide and paper rest to control and facilitate the formation of the marks, the repetition whereof, it is found, trains the hand and arm of the students of chirography.

SAFETY RAZOR.—E. P. MCCOLLOM, 810 North Avenue W., Alleghany, Pa. The improvement is in that type of safety razors in which a reversible blade is secured detachably upon the toothed head or guard, and more particularly in such sub-type as includes a spring handle having the extremities so constructed that they are adapted to enter notches or open slots in the blade, and thus serve as a means for operating the latter.

Hardware and Tools.

WRENCH.—EDWARD J. MARSHALL and GEORGE P. PAVLIK, Ruth, Neb. This improvement in wrenches has for its object the provision of a convenient wrench of the alligator type, comprising a handle, a fixed and a movable jaw, and having means for moving the latter jaw toward and from the fixed



WRENCH

jaw, and for locking it, in adjusted position. As shown in the illustration, the corner plate of the wrench is removed. The lower jaw is fixed and the upper movable jaw is provided at its inner end with an enlargement filling the recess. At the center of the recess the jaw is perforated and counterbored around the opening to secure the hub. The wrench is simple and compact, and the parts are easily assembled.

FOLDING BRACE.—F. D. TURNER, Box 84 Woods Cross, Utah, and N. DEE CORNIA, Salt Lake City, Utah. It is well known that one of the most inconvenient tools to pack away is the ordinary carpenter's brace. An object of the invention is to provide a device which is capable of being folded up into a compact form so as to occupy little room in a tool chest or carrier, and which can be easily adjusted to the proper working position.

Heating and Lighting.

GARBAGE CREMATORY.—RALPH E. NYE, Hobart, Okla. In this case the invention is an improvement in furnaces for use in incinerating garbage and has for its object to provide a novel construction in which garbage and the like may be readily moved into the incinerating chamber on a car adapted for

GARBAGE CREMATORY

the purpose and may be effectively dried and burned. The walls of the apparatus may be of brick or other suitable material. A vertical cross section of the apparatus is shown in the accompanying drawing. The apparatus may be used for cremating dead animals and for consuming garbage excrement, manure and other obnoxious filth requiring intense heat.

Machines and Mechanical Devices.

MACHINE FOR CONVERTING PULP INTO SHEETS.—H. G. HOGGINS, Au Sable Forks, N. Y. This wet machine forms paper or other pulp into sheets, and delivers the same in a partially dry state. It has an increased capacity over machines of the same general type, and in which the sheets are delivered with a relatively small amount of moisture and in uniform lengths and widths and without the use of knives, pins or shears and without substantial waste of the pulp.

PLYING MACHINE.—C. F. KOHLERUS, Washington and Ellis Streets, Augusta, Ga. In this machine the weight is in the center range of the supporting surface, and below the same thereby greatly increasing the stability and lessening the liability of upsetting by unexpected gusts of wind. In case the motor or motors should stop the planes would permit the machine to settle down gradually to the earth in the manner of a parachute.

MACHINE FOR REMOVING WASTE GILDING.—R. J. CAMPBELL, Jr., R. M. SCANLAN, and W. BRADY, 10 May Street, New Rochelle, N. Y. The invention refers to a machine for removing the excess gilding material from a cover after lettering or figuring has been impressed thereon, and to escape off the waste without danger of injuring the covering. It provides a rotary buffing member with a movable table adapted to adjust the work into and out of engagement with the buffer, and with means for adjusting the position of the table.

ESCAPE VALVE.—J. D. BROWER, Jr., Palodic Grove, Cal. This invention relates to valves for use in connection with water mains and the like, to permit the escape of gas or air from the main when the water or other fluid is allowed to enter the same, and relates more particularly to a device of this class comprising a main valve adapted to control the escape of gas or air from the main, and an auxiliary valve controlling the main valve, and itself operable by the liquid in the main or conduit.

PLUMBING VALVE.—H. B. GILSON, care of Ambridge Savings Trust Co., Beaver, Pa. In the present patent the purpose of the invention is the provision of a cheap and efficient flushing valve which will operate with any water pressure, and which may be adjusted from without to control the flow of water to meet the requirements, although the water pressure may be greater or less than normal.

VENDING MACHINE.—E. L. ROBINSON, Fire Station No. 2, Topeka, Kan. The object here is to provide a device which upon the insertion of a coin of the proper denomination, will deliver a measured quantity of unshelled nuts into a shelling device and thence into a bag, which has been taken from a pile of the same and held in the proper position by mechanism actuated by the same coin.

BLUE PRINT WASHING AND DRYING MACHINE.—O. HOOPS, 560 Park Avenue, care of Bldg. Bureau, New York, N. Y. The aim in this invention is to provide a machine having two endless belts, having sprocket openings at their sides, which are disposed against each other, and which run over rollers with sprocket teeth journaled in a casing containing tanks and a compartment for respectively washing and drying the blue prints. The last are conveyed down the belts through the machine, and are introduced and removed at points outside the casing where the belts are spaced from each other.

AIRSHIP.—C. V. JOHNSON, Box 1396 Goldfield, Nev. An object of the improvement is to produce an air ship having a construction rendering it easily manageable, having improved means for maintaining its equilibrium and for directing the course of the air ship. A further object is to provide an arrangement whereby the air ship can float and be propelled in water in case it should alight upon that medium.

MEANS FOR THE PROPULSION OF AUTOMOBILE TORPEDOES.—ANDREW E. JONAS, Picard Agent, Plume, Austria Hungary. The object here is a means of propulsion specially adapted for obviating numerous defects, at the same time diminishing the friction due to the passage of the shafts through stuffing boxes. This is obtained by arranging the axes of the motor cylinders of the group in planes parallel with the longitudinal axis of the torpedo and below the axis of propulsion, in the direction of running, and also of increasing the stability of the torpedo by lowering its center of gravity. This construction allows of connecting rods and crossheads of normal length. Means provide a hermetic sealing of all the parts.

PUMP.—E. J. HARPER, Jr., 522 W. 161st Street, New York, N. Y. Among the principal objects which the present invention has in view are: To provide means for counteracting the swirling of the water within the barrel of a pump and in the delivery column thereof, and to provide in a rotary pump devices for correcting the swirling of the water as it is being delivered from the various blades or fins.

SEWING MACHINE ATTACHMENT.—D. WARD, O. C. BRITSCH and M. FERGMAN, New York, N. Y. The object here is to provide an attachment for sewing machines whereby the motor, and controller therefor will be in an unexposed, unobtrusive position, and wherein either or both the motor and controller can be readily detached for the purpose of renewing or exchanging.

VENDING MACHINE.—C. H. SCOFIELD, Cherry Valley, N. Y. An object of this invention is to provide a coin-controlled means for automatically delivering an allotted quantity of peanuts. Further to provide a means for automatically supplying a bag or other receptacle to the purchaser, and also to provide means for keeping peanuts or other articles stored in the machine, at a suitable warm temperature.

THROTTLING DEVICE FOR MARINE ENGINES.—O. J. MCGOWAN, New York, N. Y. This improvement provides means for shutting off the steam supply of an engine when a seagoing vessel is lifted by the waves to the position commonly called pitching, provides a racking valve operable by the swing of the hull of the vessel relative to a constant vertical member, and provides a mechanism for throttling the steam supply main of a marine engine.

FLYING MACHINE.—L. C. KINCANNON, Scarbrough, Cal. This invention is an improvement in machines of the character disclosed in Letters Patent formerly granted to Mr. Kincannon the machine embodying in its construction a number of rotary carriers each having wings or vanes arranged about its axis and which are intermittently revolved to present the upwardly moving vanes or wings vertically and the downwardly-moving vanes or wings horizontally.

CONCRETE WALL MOLDING DEVICE.—R. W. FULLER, R. F. D. No. 2, Selling, Okla. An object of this invention is to provide a device comprising movable side members forming parts of a mold, said members being so arranged that they may be securely fastened together when the form is being molded, and can be removed laterally from the wall when it is desired to remove the mold.

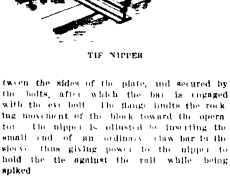
AEROPLANE.—R. P. HALL, Searchlight, Nev. This invention provides a machine with lifting capacity to support the weight of its load and a limited amount of freight or number of passengers, provides means for steering the machine vertically and horizontally, provides means for automatically balancing and maintaining the lateral stability, and provides a parachute attachment for landing in the event of damage to propelling means and supporting surface of the machine.

Prime Movers and Their Accessories.

INTERNAL COMBUSTION ENGINE.—I. F. FRIEND, 17 Stat. Street, Norwalk, Ohio. The object of the invention is to provide an engine having an arrangement of parts such as will secure the maximum horse-power with the minimum consumption of fuel. Further, to secure a perfect mixing of the charge so as to secure the utmost efficiency from the fuel. Further, to prevent the overheating of the engine.

STARTING BURNER.—H. W. GARDNER, care of Farmers' & Merchants' Bank, Springfield, Mo. This invention comprehends a burner of rather simple construction having its various parts suitably arranged, whereby oil in a liquid form and air under pressure are admitted directly into the burner, the air in making its escape serving to atomize the oil and thus form with it a combustible mixture.

Railways and Their Accessories.



TRACK RAIL.—J. G. MOORE, care of P. S. JENNINGS, 90 West Street, New York, N. Y. For the purpose of preventing accidental unscrewing of the nut it is made in sections and the opposite faces of the sections are provided with saw surfaces for pressing the sections away from one another against the threads of the bolts to lock the nut in place at any desired point along the bolt and means for locking the nuts and bolts together to prevent the same from turning.

CROSS TIE.—W. L. JONES, Chase Mills, N. Y. This invention relates to cross ties for use with railroad track rails and the like and has reference more particularly to a cross tie which comprises a body and rail supporting means at each end thereof mounted to swing into and out of normal positions and having a limited movement longitudinally of the body, this movement serving to raise or lower the rail-supporting elements.

CAR STEP REGISTER.—R. M. BAUCH and L. R. BAUCH, Neillsville, Wis. This invention comprehends a number of steps provided with depressible platforms there being two narrow steps to each rail support ing means at each end thereof mounted to swing into and out of normal positions and having a limited movement longitudinally of the body, this movement serving to raise or lower the rail-supporting elements.

CAR STEP REGISTER.—R. M. BAUCH and L. R. BAUCH, Neillsville, Wis. This invention comprehends a number of steps provided with depressible platforms there being two narrow steps to each rail support ing means at each end thereof mounted to swing into and out of normal positions and having a limited movement longitudinally of the body, this movement serving to raise or lower the rail-supporting elements.

TIE NIPPER.—WILLIAM A. SCOTT, Consul, Ala. This device is to be united beneath the rail by a perpendicular slot and placed for operation. In this operation the block forms a fulcrum for the bar, and the bill may be lengthened or shortened to suit condition. The device is assembled by first passing the eye bolt through the slot with the threaded end pin in place. The block may then be placed be-

TIE NIPPER

tween the sides of the plate, and secured by the bolts, after which the bill is engaged with the eye bolt. The dangling knuckle rock ing movement of the block toward the opera tor. The nipper is effected by inserting the small end of the bill in the slot in the sleeve, thus giving power to the nipper to hold the tie against the rail while being spiked.

Pertaining to Vehicles.

PERCUSSION MECHANISM FOR AUTOMOBILE TORPEDOES.—A. F. BOOKS, 2 Via Volosca, Fiume, Austria Hungary. The object here is the improvement in the percussion mechanism of automobile torpedoes in which the striker is constituted by the inertial reaction by a lever connected with a releasing member acting by inertia and it has particularly in view to improve the conditions under which the mechanism operates and the certainty of its operation.

NOTE.—Copies of any of these patents will be furnished by the Scientific American for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Making each day's shave a pleasure

You men who find shaving an effort that ends in a smarting, sore face, can now have a cool, smooth, comfortable shave by using the

New

TORREY Honing Strop

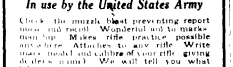
The sharpening side is dressed with our wonderful new sharpening preparation, that will last a lifetime without renewing. Just strop your razor on this surface once or twice a week and on the leather finishing side before and after each shave

Ask your dealer to show you the new Torrey Honing Strop If he cannot, write to us and we will see that you are supplied Our booklet, all about shaving, sent free on request.

Get a Torrey Razor—the best made.

Every dealer who is not now selling the new Torrey Honing Strop should write at once for our special proposition

J. R. TORREY & CO.
Dept. G, Worcester, Mass.



THE "BEST" LIGHT

Makes and burns its own gas. Pure white 500 candle power light more brilliant than electricity or acetylene and cheaper than kerosene Costs no shadow Costs two cents per week per lamp No dirt, no grease, no odor Used in every civilized country on earth Over 200 styles Every lamp warranted Agents wanted Write for catalog

THE BEST LIGHT CO.
117 E 5th St., Canton, O

Maxim Silencer

In use by the United States Army

Checks the muzzle blast preventing report noise and recoil. Wonderful aid to marksmen Sig. Makes rifle perfectly accurate Attaches to any rifle Write state model and caliber of your rifle giving delivery name. We will tell you what Silencer you need. Free.

MAXIM SILENCER, Hartford, Conn.

SPENCERIAN STEEL PENS

For the "Spencerian" copper-plate.
For the newer vertical style
For the heavy bold hand
There's a Spencerian Pen for every handwriting—finest points to broadest stubs
All have the unique Spencerian elasticity, smoothness and durability
Sample card of 12 different styles and 2 good pen holders sent for 10 cents.
SPENCERIAN PEN CO.,
349 Broadway, New York.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full limits to correspondents are printed from time to time and will be mailed on request.

(12558) R A S says: 1 What is the temperature at which glass and quartz melt? A. Glass gradually softens as it is heated until further heating produces no further change. It does not become a freely flowing fluid at any temperature, but only a thick, viscid substance which flows like cold molasses. Different kinds of glass begin to soften at widely different temperatures. Any glass may be heated probably 400 deg to 600 deg F without becoming soft. Quartz is melted only by the electric arc, which has a temperature above 6,900 deg F. 2. What is the temperature at which mercury vaporizes? A. Mercury boils at 674.6 deg F. 3. What is the average amperage per cell of a storage battery when fully charged? A. The number of ampere hours of a battery is usually given by the surface or weight of plates. It differs for different makes of battery and rate of full charge and size of cell. A storage battery in a certain electric light station gave this report: 156 cells, 25 positive and 25 negative plates each, at 10 hour discharge rate gave 278 horse power per hour, average volts 1.9 per cell, 204 pounds per horse-power hour. At one hour discharge rate, it gave 1,120 horse-power average volts, 1.8 per cell 500 pounds per horse-power hour. As a rule lead cells has been given .53 ounces lead peroxide for a 10 hour discharge rate, increasing to 1 ounce for 1 hour discharge rate. Ask makers of any particular form of cell will give figures of its performance upon application. 4. What is the formula for finding the wattage of a direct current generator? A. The volts given by a dynamo are determined by the rate at which the lines of force in the field are cut by the coils of the armature, and the amperes by the resistance of the dynamo as a whole. The watts are the product of the volts and amperes. These quantities are measured by the instruments in the test of a machine. In designing they are assumed, and the machine is built to give its rated output. The size of wire to be used are selected to carry the amperes without heating above the safe limit. 5. Will the color of the tube in a mercury vapor lamp have any effect on the light? What is the best color for ordinary lighting purposes? A. The color of the tube in the mercury vapor lamp will modify the light by absorption. The color to which our eyes are accustomed is that given by the sun as light containing all the wave lengths from red to violet. 6. In a mercury arc in a vessel the size of a 50 ampere tungsten, what amperage will vaporize enough mercury to break the built at 110 volts? The pressure of gas or vapor which will break down the bulb varies with the kind and thickness of the glass. No numerical answer can be given to the question as you put it.

(12559) H C says: 1 What is meant by the center of the force of gravity and where is this point situated in the earth? It would seem that if the pull of gravity is toward the center mass at the center of the earth the pull will be outward in every direction, and consequently the earth hollow. A. The center of the force of gravity upon any body is the point in the body about which the whole body is balanced. In a uniform sphere it is at the center of the sphere. It is what we call the center of gravity. All the matter in the earth gravitates toward that point, all attraction is inward toward that point, not outward from that point. If a ball could be dropped upon the earth and move into and through the material of the earth it would drop to the center of gravity of the earth. 2. How is it proved that a plumb bob is deflected from plumb by a mass, such as a range of mountains? A. It is proved that the plumb line is drawn out of the vertical by a heavy mass such as a range of mountains, by means of an engineer's instrument for determining a level line and a vertical line. An engineer's transit is such an instrument but much more accurate instruments are used by astronomers in solving this very difficult problem. When an object is vertical the plumb line is parallel to the direction of the plumb line was seen and measured. It has been done a sufficient number of times that we may rely upon the results obtained by astronomers.

(12560) C C asks: A newspaper recently gave the velocity of electricity 304,-227,000 miles per second and of light, 328,-038,800 miles per second. That has given rise to a good deal of discussion among draftsmen and estimators employed here. You would earn the gratitude of some forty or fifty of the young men interested if you would state whether or not the velocities given are correct, and if not what the correct figures are. A. The trouble with the figures which you quote for the velocity of electricity and of light is that electricity cannot be said to have any velocity, and the velocity of light is not known with a limit of exactness of 100 yards per second. The latest determination of the velocity of light by Prof Michelson of the University of Chicago is 299,860 kilometers per second, with a possible error of 30 kilometers per second. This in miles per second is 186,330, with a possible error of about 20 miles. The velocity of the electric current varies with the conditions under which it flows. Electric waves in wireless telegraphy move with the same velocity as light.

NEW BOOKS, ETC.

ELEMENTS OF THE DIFFERENTIAL AND INTEGRAL CALCULUS. By William Anthony Granville, Ph.D. With the editorial co-operation of Percy F. Smith, Ph.D. New York. Ginn & Co, 1911. 8vo.; 463 pp, illustrated. Price, $2 50

This is the revised edition of a work already well and favorably known. The fundamental characteristics of the original work have been retained; but the past few years have marked an advance in the methods of presenting to students the elements of the calculus, and these progressive methods, after triumphantly surviving the proving-ground of the classroom, have been incorporated into the revised drill book. The authors strive to make each step intuitionally as well as analytically evident to the student, and to this end graphics have been liberally employed. There are biographical sketches of the celebrities connected with the history of the calculus, and many examples and problems designed to test the quality of the knowledge at command, and to lead on to a well grounded understanding. Whether preparing classes for elementary work in applied science, or qualifying them for the more advanced problems of pure mathematics, the teacher has here a wealth of well-arranged material from which to select his lessons and develop his theorems.

THE TEACHING OF GEOMETRY. By David Eugene Smith. New York: Ginn & Co, 1911. 12mo, 339 pp, illustrated Price, $1 25

Geometry has been the object of many attacks which question the expediency of its inclusion in the mathematical curriculum. It has been condemned as removed from the real problems of human activity, taking up time that might better be devoted to some more practical branch of mathematics. The author, who is a professor of Teachers College, Columbia University, admits the obsolete character of certain portions of the old geometry, and is too fair-minded to attempt a justification of the study as being utilitarian in any narrow sense, yet his chapter, "Why Geometry Is Studied" puts forward some timely and pertinent considerations. Without siding on the one hand with those who would radically alter the body of matter now presented to students, or on the other hand with those who are blindly content with the system as it now stands, Prof Smith believes in a gradual progression toward more modern methods of treatment, and his papers are frankly addressed to those progressive yet well poised teachers who are striving to invest the subject with vitality and appeal. His purpose is commendable, his ideas well-conceived, and his plans admirably developed in the attractive volume before us.

EVOLUTION. By Patrick Geddes and J. Arthur Thomson. New York: Henry Holt & Co 1911 12mo; 256 pp. Price, 75 cents net

Taking the evolution theories as the canvas for their picture, the authors unroll before us, with the effect of panoramic distances, long perspectives and shifting skies, what they have striven to make "a rational vision of world-development." They show us that in spite of the variations of age, sex, origin, grouplings, and occupation every generation has much more in common than its individuals realise. They develop the theme of unity in diversity, of order in the midst of change, until there grows within us a clear conception of the nature of this continuous progression—of this organic and inorganic individual and social mode to which we give the name Evolution. Recent research stimulated by Darwin made the world almost blind for a time to the pregnant potentials of the social perspective in its application to evolution. The authors avoid the mistake of forced interpretation may meet and merge into a clear focused projection of the universal development.

SPICES. Their Histories. By Robert O. Fielding. Seattle, Washington: The Trade Register, Inc. 1910. 16mo.; 61 pp., illustrated. Price, 50 cents.

"Spices" is a reprint in booklet form of several articles originally published in the *Trade Register*. Its information is particularly directed toward retail grocers, and is alphabetically arranged under the various spices-names, each section consisting of a description of the variety, its manner of growth, and its chief uses, with an occasional caution as to the substitutes of the market.

A Home-Made 100-Mile Wireless Telegraph Outfit ¶ Read Scientific American Supplement 1608 for a thorough clear description, by A. Frederick Collins. Numerous adequate diagrams accompany the text. Price 10 cents by mail. Order from your newsdealer or from MUNN & CO., Inc. 361 Broadway, New York

Classified Advertisements

Advertising in this column is 7 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

BUSINESS OPPORTUNITIES.

DUPLEX STEAM PUMPS—Offers are solicited by a firm of Russian importers for duplex steam pumps for boiler feed, mining operations, etc. Only firms not selling on commission basis need apply. Offers, if possible in German, should be addressed to Box 1641, Munn & Co., 361 Broadway, New York.

TO INVESTORS—Large manufacturing concern with a trained selling force covering the whole country will manufacture and market on royalty basis any article that can be sold by sample at a large profit; sum for which a large demand exists. Address with full description: Machinery, P.O. Box 3418, Boston, Mass.

FOR SALE.

LOCAL REPRESENTATIVE WANTED—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to go into a big paying business without capital and become independent for life. Write at once for full particulars. Address Box 773, Marden, Penn. The National Co-Operative Realty Company, L 108 Marden Building, Washington, D. C.

PATENTS FOR SALE

FOR SALE. Patent No. 997,197, adjustable shaving brush. Turn of the handle adjusts bristle to any desired way; simple and cheap to manufacture. Address Box 488, Camden, Arkansas.

WANTED.

WANTED—A man or woman to act as our representative; no canvassing; position permanent; income necessary $60 to $90 per month. Nothing to sell. Send stamp for particulars. Sales Association, 35 Association Bldg., Indianapolis, Indiana.

MISCELLANEOUS.

MOTORCYCLES CHEAP.—Send today for free catalog of new and used motorcycles. Also motorcycle accessories and sundries at half usual prices. Everything guaranteed. If you want to make money in motorcycles, write Motorcycle Mart Manufacturing Company, Dept. M, Glenbrook, Conn.

FREE—"INVENTING FOR PROFIT" Magazine. Send us your name and we will send you this magazine absolutely Free. Before you invest a dollar anywhere—no matter what the investment is—write and get our magazine. If you intend to invest $10 or more a month, write us how much you want to invest and how to invest. Different classes of investments. Find Marketing Power of your money. Our magazine is unequaled. If you want to make money, write Publisher, Dept. 27, Chicago, Ill.

How Russia Plans to Build Up Her Merchant Marine

To the Editor of SCIENTIFIC AMERICAN:

Perhaps no other nation on the face of the earth approaches the United States so closely as does Russia in the basic economic conditions governing the general trend of development of the national industries. Both countries are at present facing a crop of strikingly similar industrial problems of grave moment, arising directly out of the policy of protectionism *per se*. Conspicuous among them looms up the problem of a national merchant marine, which formed the subject of thorough-going study and foreign investigations by agents of the Department of Trade and Manufactures, as well as of repeated turbulent discussions in the national Duma.

The entire session of the Council of Ministers of August 4th was devoted to dissecting various phases of this problem Legislative measures were laid before the Council, and commercial aspects discussed, looking to the encouragement of national shipbuilding on the one side, promulgation of a foreign merchant marine on the other, and of the Russian export trade in general.

One question was settled with not a dissenting voice, namely, that the idea of promoting national shipbuilding by imposing prohibitory or even discriminating duties on foreign built ships should be discarded. Like the United States, Russia is at present building enough ships for the coastwise traffic and the internal seas and waterways (*Cabotage*), but Russian-built ships cannot even dare venture into competition with foreign-built vessels outside of the tariff-shielded Russian domains. And precisely like the United States, Russia must have a merchant marine, if it were but to insure the future of the Russian navy The two phases of the problem were dealt with separately, and two distinct solutions were finally arrived at by the Council, viz.:

Free Ships—To stimulate Russian foreign navigation and to promote the Russian export trade, saving hundreds of millions annually on carrying freight, passengers, and mails

Differential Subsidies—To aid the handicapped Russian shipbuilders to the extent of equalizing as nearly as possible the cost of building them at home and abroad

Foreign-built ships are to be admitted into Russia free of duty until January 1st, 1913, pending further legislation On the other hand, two separate scales of differential subsidies were adopted, in proportion to tonnage, for home-built merchant vessels, which are to navigate the foreign seas, as well as the river Danube and its tributaries. The first scale relates to iron steamships, the other provides for iron sailing vessels, including the so-called auxiliary craft

The subsidies for the first category range from 105 to 65 roubles per ton of gross capacity. Ships of the second category are subsidized to the extent of 84 to 52 roubles per gross ton In certain specified instances the schedules are modified in reverse proportion to tonnage. Over and above the tonnage subsidies, special subsidies are provided for motive power—whether principal or auxiliary—to the extent of 35 roubles per horse-power indicated. Further subsidies are to be granted for overhauling and installation of new boilers and machinery, at the rate of 1 R. 50 Kps. per pood (36 pounds) for the boilers, and 5 R. 50 Kps per pood for machinery.

This subsidizing of home shipbuilding is tentatively fixed for the period of fifteen years. The rate of subsidies will remain stationary during the first seven years, whereupon they will be reduced annually by 6 per cent.

With the view of obviating the possible artifices on the part of shrewd foreign shipbuilders, contriving to utilise Russian subsidies to their own advantage, a time limit of three years of Russian service from date of registration of the ship had been fixed. If the ownership of the vessel should be transferred abroad prior to the expiration of this time limit, any subsidies received from the Russian government for construction or overhauling must be refunded in full to the exchequer.

In this way Russia plans to stimulate her export trade, foreign merchant navigation under her flag, and shipbuilding at home. It won't be long before the effect of these measures will become manifest, for the official encouragement in either direction provides sufficiently weighty inducements to promote immediate activity in the field contemplated

We need not expatiate on the immediate trade-booming effect that the upbuilding of direct shipping between Russia and the United States is bound to produce The American exports to Russia will go up by leaps and bounds.

In fact, they are going up already, owing solely to the development of Russian steamship traffic from Baltic to American ports. Russia imports over $50,000,000 worth of raw American cotton alone, all of which practically has been handled by the British shipping up to the current year The establishing of direct steamship service to the Baltic ports has resulted forthwith in a loss to the British shipping trade, amounting to $1,508,000 in the first five months of the current year, and a substantial decline in the volume of the British exports to Russia For the first time in the history of the American foreign trade, the United States has dispossessed England of her second place among importers to Russia, next to Germany. The British exports to Russia fell off from $21,043,627 in the first five months of 1910 to $24,423,990 for the corresponding period of this year. (This including even the unprecedented advance in the export of woolen yarns, which attained $1,500,000.) In the same time, the exports of the United States rose from $21,043,627 in January to May, 1910, to $28,297,237, respectively, in 1911. *An increase of almost 35 per cent.*

The exports in agricultural machinery went up from $4,867,000 to $8,760,000 (an increase of 80 per cent), other American specialties, from $1,217,000 to $2,920,000 Raw cotton went up to $16,646,000, an increase of $1,703,000

These figures are so strikingly decisive and pointed as to stand in no need of any elucidating comment.

New York, N. Y. ED. *R. A. M.*

The Merchant Marine Problem

To the Editor of SCIENTIFIC AMERICAN:

Having read your articles on shipping in the special number of the SCIENTIFIC AMERICAN, I feel prompted to bring to your attention a phase of the question not touched upon—the crews.

I will say at the outset that I was originally a "subsidy" advocate, and would not denounce some forms of that scheme yet, in fact would at the time have accepted the bill presented by the late Senator Hanna, in spite of its abuses

I fully believe a system of subsidies (make it mail subvention, naval reserve subvention, or what you would) would result in an increase in mercantile marine, as witness the German flotilla in which the German government guarantees a dividend of 7 per cent to the North German Lloyd Company, thus enabling it to operate at cost. (Hon. William Bill Sulzer kindly note this.)

So much exaggeration has been made of the evil results of a subsidy scheme, though, that it is useless to try it any longer; further, if we resort to discriminating duties, we must remember that two can play at that game.

The one scheme left is to admit foreign-built vessels (of course, only to be engaged in foreign trade). This would be a good idea, but taken by itself would result in nothing if we did not also admit their crews

For purpose of illustration, compare a vessel of the same size in four other prominent marine nations with one of ours, for instance, American steamer

Special Fabrics

For Sportsmen's Apparel

Forestry Cloth (Shade No. 65) is a unique fabric, made by us exclusively, for sportsmen's clothing. It is *strictly pure, all wool worsted of highest grade*—the only material entirely satisfactory to the hunter or camper-out.

Forestry Cloth comes in a beautiful Olive Green—a more perfect shade for the purpose could not be found—and in various weights.

Forestry Cloth will stand the roughest use, holds its shape and appearance under all conditions. It is wind proof and sheds water. Adopted by the United States Government as standard for the Forestry Department.

Oiwaste Cloth (a fabric similar to the above in weave) is made in an attractive shade of light brown, and is especially suited for riding and driving clothes, motorists' apparel, outing suits and raincoats.

Samples of *Forestry Cloth* and *Oiwaste Cloth* sent upon request And if you are unable to procure these fabrics from your tailor, we will see that you are supplied upon receipt of price. When ordering specify fabric and number of yards desired *Forestry Cloth* $2 75, *Oiwaste Cloth* $3.50 per yard.

AMERICAN WOOLEN COMPANY'S BLANKETS

For Camp, Bungalow and General Outing purposes, meet every requirement for warmth, comfort and wear. Priced from $3 50 to $10 00, according to weight, design and quality If your dealer does not carry them, write us and we will tell you who does or see that you are supplied

American Woolen Company

Wm M Wood, President.

We Want You To Know About Oswego Serge

YOUR EYES TELL YOU that Oswego Serge has the color, the finish and the "drape" seen only in fabrics of highest caste.

NOW HANDLE Oswego Serge. You get that unmistakable "feel" peculiar to thoroughbred serge—soft and pliable. Presses well and stays pressed.

BEST OF ALL Oswego Serge will keep this same look and hang, through seasons of service—it's woven to wear and resists wrinkles

YOU WILL FIND that we make the best in all the woolen world

In order to be sure of the cloth when ordering a custom suit from your tailor or a ready-to-wear suit from your clothier insist on *Oswego Serge*

If unable to obtain *Oswego Serge*, send us the name of your tailor or clothier, accompanied by money order or check for quantity desired at $3 00 per yard, and we will see that you are supplied Samples furnished on request.

Order the cloth as well as the clothes.

PARKER, STYLES & CO., 295 Bluford Avenue, Brooklyn, N. Y.

"Cherokee," of 2,557 tons, British steamer "Critic," of 2,600 tons, German steamer "Sonnenburg," of 3,477 tons; Dutch steamer "Teutonia," of 3,200 tons, and Norwegian steamer "Fortuna," of 2,994 tons. The cost of operation shows that the Norwegian boat has a captain at $120 a month and four able seamen at $10.50 a month each; the Dutch vessel, captain $121.50 a month, and seven seamen at $12.96 each; German, captain $102.11 and six seamen at $13.33 each, British, captain at $92.23, and seven seamen at $20.75; while the American captain gets $175 a month and he has nine seamen at $25 a month.

This may not look so formidable a foe for the American, but the wages of the entire crew of the American boat amount to $16,620 a year its nearest competitor, the British vessel, costing but $10,220 per annum, while the total wages on the Norwegian boat amount to but $6,128 per annum. Under the Hanna bill the "Cherokee" could have earned something between $10,000 and $12,000 per annum, if kept constantly in business; this would have made her capable of competing against even the Norwegian boat.

Suppose we cut the crews of foreign-going American vessels down to the force required of their competitors. Will they work for the same wages or eat the same food the foreigners put up with? The only way I can see to overcome the difficulty is to allow free registry of boat, crew and pantry, and even "load water line," an arrangement which allows boats of some nationalities to take in more cargo than those of other countries.

Another stumbling block is the insurance. We had quite a bit of information about the great influx of American "clippers" on the British registry when that government granted them permission, but so far as I can find there appears to have been only some 20,000 tons of such vessels that changed flags when the British insurance companies came to the rescue of the British shipbuilders and refused to insure either ship or cargo unless the ship were built according to their specifications and under the supervision of one of their agents.

Let us stop scrapping among ourselves and do something, if only to a certain limit. I can see no reason why we should not, for instance, admit to registry "for foreign trade only" all vessels of which a majority of the stock was owned by American citizens on the 1st day of July just past and allow them to have the same officers and crews and standard of feeding as they were required to have under their present flag.

BUSHROD M. GORDON

Washington, D. C.

The Role of the Cruiser Dreadnought

To the Editor of SCIENTIFIC AMERICAN:

In your issue of October 14th, a letter from Mr. A. B. Irwine brings up the oft-mooted question of battle cruisers, and suggests that the United States construct some of this type immediately or be hopelessly handicapped in a modern naval engagement.

The point at once arises as to whether these 30-knot eight-gun cruisers are to be used only as scouts, as your correspondent seems to think. Ten million dollars is a lot of money to pay for a scout, and to my mind scouting was not the primary purpose of these vessels. The Russo-Japanese war and battle conditions in our own navy have shown that swift 25-knot destroyers with a wide cruising radius are best adapted for scouting, being less easily seen and almost impossible of pursuit. The question of commerce destroying has also been considered, but the presence of a couple of wicked looking destroyers will bring down the flag of a merchantman as quickly as a cruiser dreadnought.

These vessels are being built by Great Britain, Germany, and Japan, *not as a substitute* for dreadnoughts, but *an addition* to the regular programme, their chief work being to operate together in a flying squadron, capping the enemy's column, throwing it into confusion, if possible, and then retiring, leaving the heavy work to the dreadnoughts.

It is well known that these powerful-looking cruiser dreadnoughts can not stand closer in battle than 10,000 yards to a column of the *same number* of pre-dreadnought battleships such as our "Connecticut" class, on account of their thin armor.

As long as we possess high-speed destroyers equipped with wireless, we need have no fear of not locating the enemy; the disadvantage would appear when the battle was under way. Of course it would be very nice for the United States to have these cruiser dreadnoughts, say one each year, but it would also be nice if we could have more destroyers and the proper number of colliers and other auxiliaries. It is simply a question of money, and being limited in this, it would be folly for the Navy Department to follow any other but its present plan of constructing two super-dreadnoughts a year, equal in power to the latest foreign ships. We will shortly slip back to third place in the naval ranking, and now even this very conservative programme is in danger. No one would think of comparing the cruiser dreadnoughts with our "Washingtons" or "Chesters." We might as well compare the "Oregon" with the "Neptune" of the British navy.

But owing to financial limitations, this type and many other necessary accessories to our battle line will be missing from our building programs for some time to come.

HAROLD M. KENNARD.

Brooklyn, N. Y.

The Pumps Used in Uncovering the "Maine"

IN our issue of September 2nd we published an article on the uncovering of the "Maine." No small share of the credit of the work accomplished is ascribable to the special pumps employed in the performance of the task. These were of the type technically known as the Jeanesville double-suction split-casing pump.

In the double-suction pump, the incoming fluid enters on both sides of the impeller and discharges from the impeller into a common vortex chamber. This double suction construction gives a perfect rotative balance and eliminates all difficulty encountered from end thrust, which is so troublesome in pumps of other designs.

The casings and bushing boxes are split horizontally, which permits of ready access to all interior parts of the machine. The design is such as to accomplish this without breaking any pipe joints or other connections and without disturbing the shafting, or deranging the alignment of the pump and prime mover.

Two ring-oiling bearings with split renewable bushings are used one on each side of the pump, entirely separated from the casings by deep stuffing boxes, making it impossible for grit or dirt to work into the bearings.

These features are of the greatest importance in operations where the conditions are so severe as those encountered in the work of raising the "Maine" and others, on account of the constant liability of various solid and semi-solid objects and materials entering and clogging up the pumps. It is necessary easily and quickly to reach and examine all interior parts of them.

The Current Supplement

THE question whether other orbs beside our own earth might be inhabited by living creatures is one which appeals to the imagination with peculiar interest. A scientific discussion of the conditions on different celestial spheres with this question in view is given by H. C. Wilson in the current SUPPLEMENT.—A new type of continuously working filter press which is described, should prove of interest to those engaged in industrial operations.—Liquid fuel is now being used in the production of steel. An illustrated article deals with this subject.—Mr. A. C. Rateau writes on the subject of turbines in warships.—We have all heard of the importance of proper mastication of food as a necessary step for a complete and healthy digestion. There are, however, other reasons why thorough mastication is essential to the general health of the individual. This subject is discussed very lucidly in an article derived from the *Dominion Dental Journal*.—An article illustrated with very fine views of the historic Sea of Galilee is contributed by Harold J. Shepstone.—Our Paris correspondent writes on the future of the aeroplane in army service.—An interest-

The Sensational Book, "Typewriter Secrets"

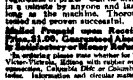
has entered the typewriter world in a flutter. It tells about the 64 printed on typewriters, the mechanical subtitles and the values of duplicating boards. Tells you how you can get a good mechanical Visible typewriter at a price never heard of before, how you can rent a Visible each month, how you can buy it or hire it without deposit. Just write "Send the Book," Mr. Fox. It is wonderfully interesting, even if you are not in the market.

Typewriters Distributing Syndicate, 186 Jill S. State St., Chicago

MAKES A PHONOGRAPH SOUND LIFE LIKE

THE Moore Clarifier is a remarkably little device unable to fit in ratio between reproducer and horn of phonographs. It renders the sound loud, clear and lifelike and eliminates that unpleasant metallic effect which is more or less common to all phonographs, regardless of price. Can be attached

PAT. APP'D FOR



in a minute by anyone and lasts as long as the machine. Thoroughly tested and proven successful.

Mailed Prepaid upon Receipt of Price, $1.00. Guaranteed Satisfactory or Money Refunded.

In ordering please state whether for Victor-Victor, Victrola, Edison with cylinder or metal attachment, Columbia Disc or Columbia Cylinder. Information and circular matter free.

MOORE MFG. CO., 1 Moore Bldg., Dayton, Ohio

A LAMP LIKE THIS IN EVERY ROOM

10-26

Actual candle power, 300 to 400. Uses kerosene (coal oil). Gives a light whiter than electricity or gas. Over 100 times more powerful than ordinary lamps. Costs 1c. per week per lamp. Burns 10 hours on one gallon of kerosene. Simple, odorless, noiseless, safe. Guaranteed 5 years. Agents wanted. Good territory still open. Sample lamp sent for examination. ARMSTRONG AND BLOUNT MFG. CO., 902 Main St., Peru, Ill., or Portland, Ore.

THE 'TABLOID' FIRST-AID

Ready-for-Accidents outfits for motorists, aviators, travellers, home, farm, workshop, camp, etc

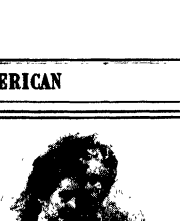
ing and promising new departure in the field of automatic aeroplane control is the Doutre stabiliser, which is described somewhat in detail.—Some years ago attention was drawn, principally by Gayley, to the advantages obtainable by drying the air used for blast furnaces. Two writers in recent French publications describe a method of drying the air with calcium chloride which offers certain advantages over Gayley's method. An abstract translation of these articles appears in our current issue—Dr J A Harker of the National Physical Laboratory, Teddington, England, gives a most instructive review of recent advance in high temperature measurement.

Phosphates in the Pacific

IT was thought a few years ago that all the phosphate and guano beds of the Pacific Islands, after yielding millions of dollars worth of fertilizers, were at length exhausted This view has been changed by the discoveries made since 1907

The largest phosphate industry that the Pacific ever saw is now in progress on two neighboring islands, the German island of Nauru, the most southern atoll of the Marshall group, and the British island of Banaba Hundreds of islanders as well as Chinese and Japanese laborers are working in these phosphate diggings, and though the industry is still very young, it is yielding over 2,000 tons of prepared phosphate a year. The yield is increasing as fast as improvements are made in mining the rock and in facilities for shipping it

The beds in the two islands seem to be similar in the quality of the rock, and though their thickness has not yet been ascertained the quantity of phosphates is enormous Numerous borings have been made all over Nauru, which comprises about 5,000 acres These borings were not meant to ascertain the total phosphate content, but merely to determine if there was enough of the rock to pay for the erection of expensive works



They were sunk, therefore, only to a depth of ten to fifteen feet The Germans report that under the superficial earth the entire 5,000 acres are covered with phosphate beds to a depth of at least ten or fifteen feet, and they do not know how much deeper the beds may go, for they have not explored lower levels

They add that it will take some generations to remove the phosphates already revealed. The two companies, German and British, that secured concessions to mine the rock, have joined their interests and are working together. The outside public has nothing to do with their enterprise except to buy the product

When the German flag was raised over Nauru, twenty five years ago, the 1,500 natives had no relations with the whites except to sell their cocoanuts for brandy and wretched firearms supplied by two or three unscrupulous traders The Germans stopped this trade, but it was long before the real wealth of the little island was discovered.

Now a great transformation has come Large steel framed buildings in which the rock is prepared for commerce have been erected, an iron pier has been extended out into the sea beyond the breakers, and lines of steel tracks lead down from the mines to the piers. But the rock is as yet taken out to the anchored steamships in small boats and the Germans have little hope of discarding this primitive method They say the surf runs too high for ships to tie up at the landing wharf

Influence of Chewing on the Condition of the Teeth.—Investigations on the children in the town of Kötzing in Bavaria showed that of those who eat hard bread the percentage with bad teeth was 6 9, of those who eat both hard and soft bread, 8.2; of those eating only soft bread, 10 5 In the town of Ibringon (Baden) the percentages before and after the introduction of soft bread were as follows: In 1894, when only hard bread was eaten, 12.4 per cent; in 1897, just after soft bread had been introduced, 12.9 per cent; and in 1901, where most of the bread consumed was soft, 20.9 per cent.

What Is Your Family Worth?

IF IT IS worth the best you can give in house and food and clothes, is it not worth the best reading as well? And the best of reading, week in, week out, fills the columns of

The Youth's Companion

Do you realize that the contents of The Companion for a year, published in book form, would make 30 volumes of the best and most varied reading?

7 vols Serials 8 vols Articles 3 vols Editorials 8 vols Little Folks 3 vols Current Events 8 vols Stories

30 Vols. 8 vols Departments for Boys, Girls and the Family 1 vol Medical & Religious 3 vols One Minute Stories 1 vol Nature & Science $1.75

All for $1.75 and every line worth while. The best gift to a family or anybody in it.

ARTICLES by famous writers, nearly 250 splendid stories, serials the year through, the Boys' Page of Athletic Sports, the Girls' Page, the Doctor's Corner, etc., etc.—all for $1.75 if you subscribe now for 1912.

Your last chance to get The Youth's Companion at the present price On January 1, 1912, it will be advanced to $2 00. Subscribe now, to-day, sending $1 75 for the 52 issues of 1912 and get, free, all the remaining 1911 issues

HOW TO GET THE FREE ISSUES

NEW SUBSCRIBERS who cut out and send this slip (or name this paper) with $1.75 for the 52 issues for 1912 will receive

Big profits in this Little Engine for you

This is Tom Thumb one of the famous engines in the I H C lines

Tom Thumb develops more than one horse-power In the shop it will operate a belt-press, emery grinder or other small machines It is powerful enough to pump all the water needed on the ordinary farm—will run the cream separator, grindstone, bone cutter, churn, small corn sheller, washing machine, etc.

This little work saver is exceptionally simple and strong and will give steady economical power for years. It is an I H C through and through It is made of the same materials and is built and tested in the thorough manner that distinguishes all

I H C Gasoline Engines

Tom Thumb comes all complete, including governor, spark plug, batteries, tools, etc. No water tank is needed The cooling is done by air.

Write for more information about I H C engines. They are made in many styles and sizes for every need. One to 50-horse power, stationary, or portable; air or water cooled; built to operate on gas, gasoline, kerosene, alcohol or distillate Also gasoline and kerosene tractors, 12 to 45-horse power Write now for catalogue and any special information you desire. NAVAL NUMBER

DECEMBER MAGAZINE NUMBER *of the* SCIENTIFIC AMERICAN ISSUE OF DECEMBER 9th, 1911

List of Contributors:

Hon. G. von L. MEYER — Secretary of the Navy — "The Business Management of the Navy"

Rear-Admiral ALFRED T. MAHAN, U. S. N. — "The Command of the Sea"

Rear-Admiral RICHARD WAINWRIGHT, U. S. N. — Aide For Operations of the Fleet — "The Fleet and Its Readiness for Service"

Rear-Admiral RICHARD M. WATT, U. S. N. — Chief of Bureau of Construction and Repair — "Influence of the United States on the World's Battleship Design"

Rear-Admiral H. I CONE, U. S. N. — Engineer-in-Chief United States Navy — "Propelling Machinery for Naval Vessels"

Rear-Admiral N. C. TWINING, U. S. N. — Chief of the Bureau of Ordnance — "Recent Developments in Ordnance"

Capt. T. M. POTTS, U. S. N. — Chief of the Office of Intelligence — "Our Rank Among the Naval Powers"

Capt. ALBERT CLEAVES, U. S. N. — Commanding U. S. S. North Dakota — "On Board a Battleship"

Commander PHILIP ANDREWS, U. S. N. — Aide to the Secretary — "The Future Sea Fight"

Lieut.-Com. LEIGH C. PALMER, U. S. N. — Director of Target Practice and Engineering Competitions — "Target Practice—How Our Men Are Taught to Shoot Straight in Rough Weather"

Lieut. D. C. BINGHAM, U. S. N. — Commander Third Submarine Division — "The Modern Submarine"

Colored Cover by H. REUTERDAHL — PHOTOGRAVURE INSERT

Illustrated by Photographs Taken During the Late Autumn Maneuvers

The period of American history which opened with the Spanish war will always be reckoned as one of the most momentous in the growth of the United States. Then it was that this Republic moved forward into its present commanding position as one of the leading nations of the world.

Two events contributed to this. First: The enormous growth of our industries, far outstripping the demands of home consumption, led to the upbuilding of our present extensive foreign trade. Second: The acquisition of Hawaii, the Philippines and our West Indian possessions, by extending our coast line into distant seas, broke down the geographical isolation of the United States and threw us into an intimate political and military relation with the whole world.

As one immediate result our Navy assumed an importance which it had never before held. The growth of our fleets since 1898 has been steady, and, until the past two or three years has been fairly well adequate to our necessities.

During the period referred to the Scientific American has lent its pages freely to the work of describing the growth of our Navy, and we believe that the intelligent interest in the Navy and its undoubted popularity have been due in no small degree to the efforts of this journal.

As a fitting climax we are in a position to announce that on December 9th we shall issue a magazine naval number, which will be written entirely by leading officials in the Navy, each of whom stands at the head of the particular branch of the service of which he treats.

No journal has ever presented an issue, dealing with naval affairs, of such value and authority as this. A perusal of the above list of writers and subjects will show that this edition will constitute a *brochure* on the Navy, written within the Navy, by its most distinguished officials.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Evolution and Geographical Distribution

WE generally think of the survival of the fittest as a principle which operates *in time*, bringing about those changes in biological species which are implied in the term "evolution." But the same natural selection which *in time* causes a closer adaptation of the organism to its environment is also potent in regulating the distribution of the several types and species *in space*. For, as climatic and other conditions vary according to the locality, the "selective influences" at work at each point of our globe differ correspondingly from place to place, and the material selected, the surviving type, thus becomes a function of geographical position. The white man of the temperate zones is ill adapted for the torrid climate of central Africa, where nevertheless thrives, physically at least, the dusky native. The latter, again, when transplanted to our climate, proves less fitted for the battle of life than the white race, as is shown by his greater death rate and liability to certain diseases.

But selection does not operate through death rates alone. Let us make a seeming digression, borrowing an example from physical chemistry. The chemist separates the more volatile constituents from a mixture by establishing local differences in temperature in a suitably constructed system, the hot portion is called a retort, the cold a receiver. The mixture is heated in the retort, and presently the volatile vapors pass over into the receiver, where they condense to liquid. We need stretch the meaning of the term very little to say that the volatile liquid is not "adapted" to the conditions of high temperature which prevail in the retort, and is thus "weeded out" and converted into vapor. In the cooled receiver the conditions are different. Here the liquid is stable, and can subsist indefinitely. This is not unlike what happens in the living world and with the human race. In the course of time the population of Europe has increased until, for very crowding, the struggle for existence has become much intensified, however much it may have changed in character. The opening up of a new world across the seas has furnished a vent whereby some of the surplus has been able to escape to a less populous region. And just as in the still of the chemist, the substance which passes over into the receiver is not the same in composition as the material originally introduced into the retort, but contains a greater percentage of the more volatile constituents, so we may naturally look for a more or less marked difference between the overflow from the old world which has settled on this continent, and the residue in the home countries. We should, in fact, expect that the settlers, and presumably through hereditary influence their descendants also, would represent the more "enterprising" element of the original population. And indeed, a strong spirit of enterprise is by common consent one of the most marked characteristics of the American nation. Somewhat less obvious, though none the less interesting, is a similar effect which has been observed in the old world. De Candolle in his "History of Science and Savants," illustrates by a number of very remarkable examples that the refugees, who, for holding fast to their personal convictions in the face of popular opinion, were expelled from their home countries during the troublous times of the sixteenth to the eighteenth century, have, together with their descendants, contributed over four times the normal share to the world's army of scientific men, thus bringing a rich reward to the countries which offered them shelter. The practically absolute sterility of Spain in the field of science has been attributed to the influence of the terrible Spanish Inquisition, which very effectually stifled all independent thought, and killed off every individual in whom the divine thirst for truth was clamoring to be satisfied.

It must ever be a cause of universal regret that some members of that same organization which did so much to cultivate art and learning in the middle ages should, in mistaken zeal, and with the crudity characteristic of their epoch, have dealt so little sympathy to some of those who helped to lay the foundations of modern science.

Perhaps the most extreme case of the segregation of a special type of individuals by a process of "distillation" into a locality widely differing in character from the abode of the main body of the species, is presented to us when we look at a map of the polar regions, such as appears elsewhere in this issue. Here we may follow the tracks of intrepid wanderers, who braved the hardships and perils of that barren waste of ice and snow which guards the earth's poles from the approach of inquisitive man. None but the most venturesome and skilled explorers have found their way into this pale; here is selection indeed, and every man in this territory a hero.

The Toll of Aviation: A Remedy

THE passing the other day of the century mark in the number of lives lost in aviation calls to mind the pioneers whose lives were sacrificed *needlessly* in the development of this great science. The last of these to lose his life as a result of his personal experiments was Prof. John J. Montgomery, of Santa Clara College, Cal., who was killed the 31st day of October, while trying out one of his gliders.

It is a peculiar coincidence that Prof. Montgomery, who had built and operated successful gliders before the Wrights began their experiments, and who, by releasing a following surface monoplane glider from a balloon in 1905, had enabled Daniel Maloney, the aeronaut, to make the first motorless flights of a quarter of an hour's duration, should fall to his death only a few days after Orville Wright had achieved success along these lines and had risen from the ground and remained aloft 9¾ minutes without the use of any motive power save gravity and the wind. A parallel coincidence was seen in the death of Prof. Langley just after the Wrights achieved in December, 1903, what he had striven so hard and earnestly to accomplish.

When we look back over the list of pioneers who have gone to their deaths as the result of their unconquerable desire to fly *themselves*, we deplore this unnecessary sacrifice and wonder how much more advanced we would be to-day if we still had Lilienthal, Selfridge, and Nicuport. Perchance the great German would have found ere this a way to utilize the intangible ascending currents of air as Orville Wright has just utilized a 50-mile gale and thus have set us all soaring in bird-like fashion, every man on his own home-made monoplane. Oh, that some means were found of communicating with the dead, that they might transmit to us the secrets and vast knowledge they have taken with them! How much faster the world would move forward in all the sciences and arts!

But since such is not the case, it behooves those talented men who still remain not to jeopardize their lives by taking unnecessary risks. The accident that snatched away Lieut. Selfridge came within a hair's breadth of claiming Orville Wright also, while in his recent glider experiments he has had some rather close calls. The death of Prof. Montgomery so soon after, shows that danger lurks even in a motorless machine; while Glenn Curtiss should remember Manley's miraculous escape from drowning when the Langley aeroplane was launched from a house-boat, and should not personally take even seemingly slight risks with his hydro-aeroplane.

The "Father of Aviation" in America, the late much-loved and esteemed Octave Chanute, followed the proper course when he secured alert and active young men such as Avery and Herring to do the real experimenting. The same was true of Prof. Langley, who was fortunate in securing the services of so eminent a young engineer as Charles M. Manley—a man capable of constructing both motors and aeroplanes, and of flying them when built.

If Edouard Nicuport had not dared to demonstrate personally for some officers his marvelous monoplane in a treacherous, gusty wind, he might again have produced a winner of the international speed race. The lamented Capt. Ferber is another pioneer who could not resist indulgence in the new, fascinating science. Had he studied it by proxy as did his fellow-countryman, Chanute, the aviation world would no doubt have had the benefit of his active brain for many years longer.

The Food Value of Bread

ALTHOUGH mankind has made use of bread in some form or other for several thousand years, there still remains much unknown about the food value and about the relation to digestion of this universal staff of life. An English study of the subject has just been completed, by a committee of the Local Government Board. This committee made use of much of the work done by experts of the U. S. Department of Agriculture.

The old controversy between the advocates of roller-mill flour and the defenders of stone-mill flour need never again be revived, in view of the results obtained by a scientific analysis of meals produced by the two processes. Not only do the roller-mill flours show a larger percentage of available nutricants, but the best grades of wheat—the so-called "hard wheats"—cannot be utilized at all in the old-fashioned stone mill; and the flours having the best "baking qualities" are produced by the roller mills. Roller-mill flours are also the whitest flours, which appeals to many on the esthetic side.

Notwithstanding the enthusiasm of many apostles of whole-wheat bread, the findings of the commission will rob them of some of their converts. It is found that the presence in food of bran—the outer coverings of the wheat grain—may be advantageous under special circumstances, but that in general it is an undesirable element in bread. Not only is the bran itself indigestible, but it interferes with the digestion of other nutrient factors in the food. For example, in one set of experiments it appeared that when milk was taken with whole-wheat bread three per cent less of the milk was digested than when it was taken alone, or with white bread.

The most important point, however, is not the manner in which the flour is manufactured, but the character of the wheat. That is, there is more difference between roller-mill, or stone-mill, flours from different kinds of wheat, than there is between the two different preparations from the same grain. It is at the same time in the direction of producing improved strains of wheat that the most progress has been made in recent years.

Advocates of the virtues of bran in food often recommend the mixing of a small quantity of whole-wheat flour with the white flour, in order to increase the percentage of mineral matter. The gain in salts to be obtained in this manner is, however, so slight, that a growing child would have to eat an excessive quantity of bread to derive any appreciable benefit from this method. With the mixed diet that is all but universal in civilized countries, we may well depend upon other parts of the ration to supply the additional mineral matter required by a growing child.

Contrary to very common belief, this report declares that the different effects upon the teeth produced by different kinds of bread, are altogether negligible. The possibility for standardizing flour is considered to be very slight at the present time, especially on account of the different kinds of wheat used in milling. Still, the differences between the various kinds of wheat flour on the market are not of serious importance.

That whole-wheat flours may contain substances of value—quite apart from their influence upon digestion—is believed by the committee to be a possibility worth considering, and they recommend scientific investigation upon this point as well as upon several other problems that arose in the course of the inquiry.

A New Use for Cactus

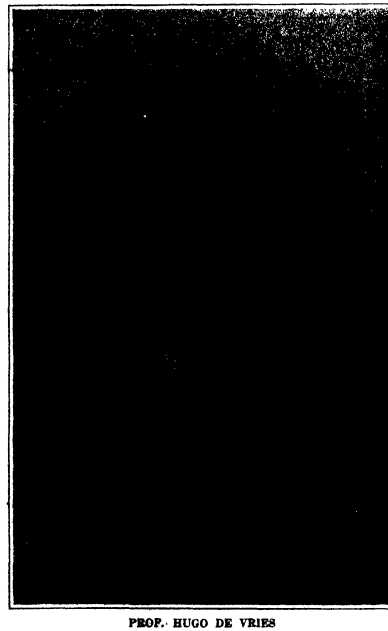
A CONSULAR report from Montevideo suggests that the people of the southwestern United States, where cactus is abundant, and often a nuisance, might follow the example of the Uruguayans and utilize this plant in making whitewash. When traveling through the rural districts of Uruguay one's attention is attracted by the fine white color of the farm buildings, even during the wet season. The whitewash is made from the sliced leaves of the common cactus, macerated in water for 24 hours. To the creamy solution thus produced lime is added. When applied to any surface, a durable pearly white appearance is produced.

Hugo de Vries

Famous for his Mutation Theory of Descent

By D. T. MacDougal, Ph.D., LL.D., Director Department of Botanical Research, Carnegie Institution of Washington

ALL students of the growth and other physical activities of plants during the past twenty years have found that any consideration of the manner by which a plant retains its rigidity, plumpness or firmness, or executes movements, inevitably brings one to know the experimental studies of Hugo de Vries, who published his first paper upon the mechanical causes of turgidity as early as 1877. A plant cell may be readily likened to a sac of living matter which holds water in its interior under a pressure which may amount to as much as 25 or 30 atmospheres, and this is possible only by reason of the impermeability of the outer wall, which is capable of undergoing a wide range of variation as to its physical properties. Outside of the living membrane of a cell is another of cellulose, and this is fully permeable. The differential behavior of the living and non-living membranes when the cell is placed in solutions of osmotically active substances, such as sugar and potassium nitrate, form the basis of the phenomena of plasmolysis and afford a clue to the conditions of turgescence within the cell. The systematic use of solutions in producing plasmolysis, and a rational interpretation of the facts, were first given by De Vries in 1877.



These results have their direct and immediate importance chiefly in plant physiology, but their wider application in the establishment of the isotonic co-efficients of various substances, together with the experiments of Pfeffer, another botanist, in osmosis, form the basis of the electrolytic dissociation theory of Arrhenius, as well as the law of van't Hoff that "dilute solutions obey the same law as gases," both conceptions of the greatest importance in the physics and chemistry of to-day.

With achievements of such magnitude to his credit within eight years after receiving his doctor's degree from the University of Leyden, and at the age of 29 (born in 1848, at Haarlem, Holland), the attainment of a foremost place among the botanists of the world, and the earned recognition as the greatest evolutionist after Darwin, seem a logical and natural development of a master mind in biological science.

His developing powers of research can be shown to be coincident with a movement in all natural sciences which occurred late in the last century by which attention was directed more and more to the transformations of energy in general and to the activities, functions, qualities and capacities of organisms in particular. Habits and performance were recognized as biologically more important than form or even structure. It was in consonance with this trend of science that De Vries, who had long been concerned with variability in organisms, should formulate a prothesis as to the mechanism of heredity, which should put forward a physiological rather than a morphological explanation of heredity, which was done with the presentation of his Pangenesis in 1889.

This splendid contribution was not solely an abstract product of the study, but represented the working hypothesis of a brilliant experimentalist intent on visualizing the mechanism of heredity and providing a working hypothesis by which a rational interpretation of the continuation of qualities from generation to generation through germ-cells could be made. Coincidently with its appearance, De Vries began to publish the results of his investigations upon variability, and mutations in plants, upon which he finally erected his Mutation Theory of Descent, in final and formal shape, about the beginning of this new century.

The extensive experimental cultures organized by deVries in the Botanical Garden of Amsterdam, yielded results of importance with regard to the inheritance of unusual characters in plants, such as torsions or twistings of stems, fasciations, bandings or cristations, as well as statistics upon the curves of variation of single characters. It was in these studies in the behavior of pairs in balanced characters in crossing, that De Vries rediscovered independently the Mendelian principles of alternative inheritance, which had remained unnoticed for a half century. The simplest illustration of Mendelianism is to be seen when a red and a white variety of the same species are crossed, the color qualities being considered as "balanced" or paired. The seeds from such a cross give rise to a progeny of plants all of which bear red flowers, that color being dominant over white. The seeds produced by this first generation of red-flowered individuals, however, generally produce a progeny, three-fourths of which are red-flowered while the remainder bear white flowers. Similar behavior is exhibited by many other qualities, although the division of the progeny does not always follow the simple formula noted. In addition, he brought to light many important things concerning xenia, atavism, derivation of economic races of plants, and effects of selection, of prime interest to a wide range of scientists, and to horticulturists, agriculturists and plant breeders. As may be seen, however, these results are to be considered as no more than by-products of his cultures, since much more important things were the center of attention. Early in the eighties, a series of observations were begun in which the successive generations of about a hundred species of plants were followed in order to ascertain exactly what resemblances might be found between parent and progeny in guarded and pure lines of descent. The behavior of one plant, a large evening primrose, *Oenothera Lamarckiana*, which had been introduced into Europe in the seventeenth century, offered phenomena of unusual interest, since it was seen to give rise to several sports, or salts, or mutants which differed distinctly from the ancestral form, and these new forms bore distinct qualities which were maintained in direct descent. It was upon such facts that De Vries founded his theory of the origin of new species by the sudden origination or disappearance of qualities in organisms.

PROF. HUGO DE VRIES

The biological public received these generalizations with indifference. In addition to the inertia of old ideas, some curious nationalistic prejudices found expression. As many English naturalists and scholars in other branches fought the idea of natural selection, when presented by Darwin, with vicious unfairness, so now a similar element was responsible for much criticism, resentful of anything which might modify the attitude of the world toward Darwinism, an attitude still recognizable in current publications. The writer of this note had the pleasure of presenting a summary of the mutation idea of evolution, with an account of the experimentation upon which it was based, to a meeting of botanists in the New York Botanical Garden in 1902, at which time some cultures of the *Oenotheras* from seeds furnished by Prof de Vries were begun, which, it is believed, constitute the first demonstrations of the main thesis outside of the Botanical Garden at Amsterdam. These experiments in New York confirmed the facts obtained in Amsterdam in every important particular, and their publication in 1903, found a rapidly growing interest in the subject in America. Prof de Vries was consequently invited to give a series of lectures in various institutions from the Atlantic to the Pacific, receiving a full measure of recognition in academic honors, which have been followed by similar expressions of appreciation from learned bodies all over the world.

A full, non-technical exposition of the mutation theory was given at the University of California in the summer of 1901 and to the writer fell the pleasure of putting these lectures into book form under the title of "Species and Varieties: Their Origin by Mutation." This book came to its second edition within a few months, being styled the "most notable scientific book of the year" by a competent reviewer, a statement apparently justified by the fact that it has since been translated into Dutch, French, and German.

A large number of the investigations which were begun as a result of his first visit to America profited by his second visit in 1905, and he has had the exceptional opportunity of seeing his observations repeated under the widest variety of climatic and other environmental conditions. These confirm the significance of the facts upon which the mutation theory was founded. In addition to the sports or mutants of the evening primroses which formed such an important part of the original evidence upon the subject, similar phenomena have been observed in many other seed plants and among the lower forms including the bacteria. The origination of new races or species in animals is not so easily observed, but still authenticated instances are accumulating. That new qualities suddenly appear in lines of descent is no longer a question, but it is still to be determined how large a part such action plays in the general scheme of evolutionary development.

Any discussion of Prof de Vries's work raises the question at once as to the relation of the new ideas he has formulated to the older conceptions of Darwin. One theological author has gone so far wrong as to write "The death-bed of Darwinism" by a misapprehension of the meaning of mutation. Darwin would have evolutionary progress by the selection and survival of infinitely minute divergences through thousands or hundreds of thousands of generations, arriving finally at types widely different from the original. De Vries holds that the organism fluctuates steadily about its average or norm, from which it does not depart beyond a certain limit, but the line of descent may, at any time, include individuals possessing new qualities not shown in any degree by the parental strain. Selection decides between these forms and those previously existing, the fittest of the types surviving. Instead of supplanting the theory of natural selection, the mutation conception has the actual force of coming to its support at a time when many of its generalizations were being recognized as notably inadequate to the full interpretation of known facts. The mutation theory defines more accurately the manner in which selection may act in addition to offering an explanation of the manner in which new capacities or qualities may arise.

Although now in his sixty-third year and nearing the age of academic retirement, Prof de Vries is deeply engaged in experimentation, and the cultures in the Botanical Garden at Amsterdam may yet yield results of a theoretical and practical importance in evolutionary science, scarcely less than that of pangenesis and mutation.

Antarctic Expeditions, Past and Present

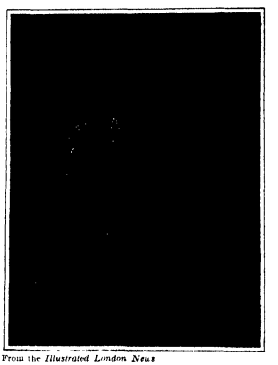
Some Heroes of Exploration

A BARREN continent, far from human habitation, utterly desolate, snow-clad, enfenced in forbidding barriers of ice. Yet around it circle and twine in shining paths the tracks of many gallant explorers, who for the last one hundred and forty years have strained every nerve to conquer those inhospitable shores. What priceless treasure, what thing so coveted of men does this lonely waste harbor, that they should brave the perils of famine and an icy death in their quest? No ordinary material reward is that they seek; theirs is an ideal goal, the thirst for knowledge, the spirit of scientific exploration, and no doubt the love of a manly fight against desperate odds, these are some of the motives that fire them. And it is for us, who stay at home in safety and comfort, reading the history of their doings, to catch some faint spark of inspiration from the exploits of those gallant men and hold as we also reap the material benefits which flow from their scientific labors.

The first antarctic expedition falls into that period which is so peculiarly replete with important events, both in the world of politics and in the realm of science. We read in a leaflet issued by the American Museum of Natural History, that in 1772, Capt. Cook of the British Navy, was commissioned by the Admiralty to command two vessels to examine into the question of the existence of a great southern continent. He sailed from Plymouth in July, reached Cape Town in October, and entered the area shown in our front page illustration near the 20th meridian of east longitude. The first part of his course will be seen putting forth a nose toward Enderby Land, which appears near the "horizon line" and to the right from the center. Cook next proceeded along an easterly course then turned abruptly south, and on January 17th, 1773 was the first person to cross the antarctic circle. Cook continued his travels, the line of which will be seen again and again in different portions of the accompanying map though part of his course lies outside the area covered thereon. In January, 1774 he reached his farthest southerly point, 71 degrees 10 minutes, near 110 degrees west a record which was not broken for half a century. It is noteworthy that Cook, the first successful antarctic explorer, not only completed the circumnavigation of the antarctic but proved the non-existence of any antarctic land mass extending north of the antarctic circle.

The next South Pole expedition of any importance was carried out under the patronage of Alexander II of Russia who appointed Bellingshausen to the command. This explorer sailed in January, 1820, with two vessels. His course also will be found sketched on the accompanying map. He crossed the antarctic circle some six times, and discovered Peter Island, the most southerly land then known. He did not, however, go quite as far south as Cook, but only reached 69 degrees 52 minutes.

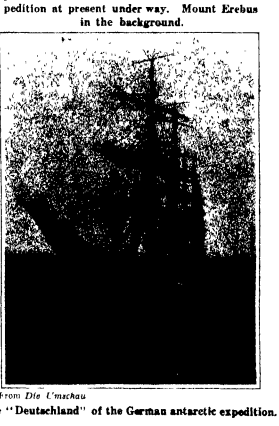
In 1823, an Englishman named James Weddell, forced two small sealing vessels southward through the sea which bears his name, to 74 degrees 15 minutes south, a point 214 nautical miles nearer the pole than Cook's farthest travel, thus breaking the record that had stood for nearly fifty years. Weddell's course will be seen on the map near the horizon a little to the left of the center.



Enderby Land, to which we referred in indicating the position of Cook's course on the map, was discovered in 1831 by Biscoe, a British sealer, exploring under commission from the merchant firm of Messrs. Enderby. The course of Biscoe will be found on the map, forming a loop thrown over the antarctic continent.

An expedition sent out by France in 1837 under Commander d'Urville deserves mention as being the last French south pole expedition until recent times.

In 1839, Lieut. Charles Wilkes at the head of the United States exploring expedition, with a squadron of six vessels poorly equipped and poorly adapted for polar work, entered the south polar regions from Tierra del Fuego. His course will be seen on the accompanying map, approaching the antarctic continent near the center of the map and following the coast line westward (to the right). In his journey through what is known as Wilkes Land, he took a course more southerly than any previous explorer known to him had traveled in this region.



James Clarke Ross, a nephew of Sir John Ross, the arctic explorer, and one who had several years of arctic experience, left Tasmania in 1840 in command of the "Erebus" and "Terror." The primary object of the expedition was to make certain magnetic explorations in the extreme south. In less than five months Ross returned to report the extraordinary results of his expedition. His course will be seen indicated by a tortuous white line tangled over the Ross sea.

Fully informed concerning the discoveries of Wilkes,

ANTARCTIC EXPEDITIONS, PAST AND PRESENT

James Clarke Ross, a nephew of Sir John Ross, the arctic explorer, and one who had several years of arctic experience, left Tasmania in 1840 in command of the "Erebus" and "Terror." The primary object of the expedition was to make certain magnetic explorations in the extreme south. In less than five months Ross returned to report the extraordinary results of his expedition. His course will be seen indicated by a tortuous white line tangled over the Ross sea.

Fully informed concerning the discoveries of Wilkes, he determined to seek high altitudes to the east of the Balleny Islands, and with little difficulty sailed into a new sea and discovered land extending from Cape Adare to the volcanoes of Erebus and Terror, 77 degrees south, a distance north and south of approximately four hundred miles. He thus reached a point considerably farther south than any attained by previous explorers. He finally reached England in September, 1843, having been absent for more than four years.

In 1874 the first steamship, the British vessel "Challenger," entered the antarctic. It was also the first to be equipped with adequate sounding and dredging apparatus. As a result of the "Challenger's" investigations the existence of an antarctic continent was proved, and the fact that a wealth of animal life covered the floor of the south polar seas was well established. The course of this expedition under the command of G. S. Nares appears on the map near the upper right-hand corner.

During the last quarter of the nineteenth century with the waning of the whaling industry in the north, and the report of the existence of large numbers of whales in the south, the small steam whalers of Scotland and Scandinavia made several expeditions into the antarctic. Among these was the "Jason," commanded by Capt. Larsen, whose course appears near the horizon to the left of the center of our map. Larsen discovered the first antarctic fossils, which proved that at least part of this region is not volcanic.

During the years from 1902 to 1904, Capt. R. F. Scott, commanding the "Discovery," a well equipped vessel manned by British navy officers and bearing a scientific staff of well qualified men directed a south polar expedition in which among others Shackleton took part. On November 2nd 1902, Scott, Shackleton, and Wilson began their heroic sledge journey over the polar ice to the south, a distance of 380 miles from their ship. They planted the British flag at 82 degrees 17 minutes south. The following winter was spent in the antarctic under conditions of intense cold, the thermometer frequently registering fifty degrees below zero and even reaching 68 degrees. It appeared at one time as if the "Discovery" must be abandoned, and the crew return on one of the relief ships that had been sent after them. But on February 16th, 1904, she was released from the ice and sailed for home. Scott's course will be seen indicated, extending roughly along the median north-south line on our map.

A Scotch expedition explored the south polar regions during 1903-1904 and among other things discovered Coats Land. The commander was W. S. Bruce, and his course appears right in the center of the horizon in our illustration.

We come now to the last and most successful of all the south polar expeditions. Early in 1908 Lieut. Shackleton on board the "Nimrod," with a party of about fifteen men, dogs, Siberian ponies, a motor car and other equipment, entered the antarctic regions near the 180th meridian. Passing through Ross Sea and along the edge of the great ice barrier they almost reached King Edward VII. Land but found further progress in that direction blocked by impenetrable pack ice. They then proceeded to Cape Royds near the volcano, Mount Erebus. Here the "Nimrod" left them and went north, to return the following spring. Relatively elaborate winter quarters were established at Cape Royds in a specially designed hut made of cork. In March, 1908, a party of six ascended Mount Erebus to its summit, 13,500 feet above sea level.

On October 5th, 1908, a party of five started on its journey to the South Magnetic Pole, which was reached on January 16th, 1909. The position of the magnetic pole was determined to be 72 degrees 25 minutes south, 155 degrees 16 minutes east. The south point of the compass always turns toward this point. Therefore, between the South Magnetic Pole and the South Geographic Pole the south point of the compass is directed due north. This party, returning to the coast February 3rd, was picked up by the "Nimrod" and taken to Cape Royds.

On October 29th, 1908, Shackleton and three others—with a supporting party of five, which turned back November 7th—set out for the South Geographic Pole. They followed, roughly, the 163d meridian east until in late November they

reached Scott's farthest south—82 degrees 17 minutes south. Christmas day found them at 85 degrees 55 minutes south, and by 9:00 A. M., January 9th, 1909, they had reached 88 degrees 23 minutes south Beyond this point they could not go on account of the hard traveling and the exhaustion of their food supply No mountains were visible beyond, and it is probable that the South Pole is situated on a level plateau 10,000 to 11,000 feet above sea level After an extremely hard return journey on short rations, Cape Royds was reached March 4th, 1909 The "Nimrod" and the supporting and relief parties were there waiting, and the next day all started for home

In addition to discovering the South Magnetic Pole and reaching a point within 110 miles of the South Geographic Pole, the main results of the journey were the finding of coal (showing that in the past this region enjoyed a mild climate), the procuring of a complete meteorological record and the discovery of eight distinct mountain ranges varying from 3,000 to 12,000 feet in altitude

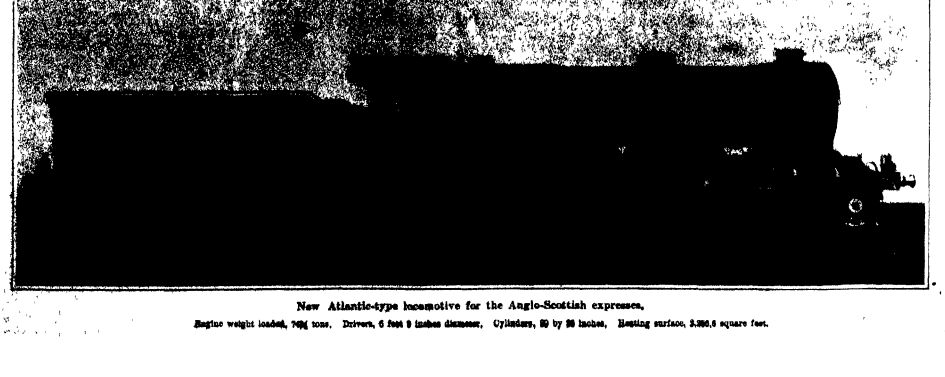
Into approximately the same period as Shackleton's expedition falls Charcot's voyage on the "Pourquoi Pas" in the Antarctic (1908-1910) In sportsmanlike spirit this French explorer refrained from entering a region which, as he considered, had been "staked out" by the British expeditions "I resolved," he writes, "to return to the region which I had begun to explore on the "Français" in 1903-1905, i e., that mountainous projection, due south of Cape Horn, improperly known under the general name of Graham Land My exact object was to study in detail and from all points of view as wide a stretch as possible of the Antarctic in this sector of the circle" Dr Charcot has presented an account of his travels in popular form in a very interesting book published under the title "The 'Pourquoi-Pas' in the Antarctic"

No less than five south polar expeditions are at present in progress or contemplated An English party is out under the command of Capt R F Scott, while a Norwegian campaign is headed by Amundsen Recently Sir Ernest Shackleton has made an appeal on behalf of an Australasian antarctic expedition under the command of his old comrade, Dr Douglas Mawson, whose desire it is to chart a stretch of unknown coastline some 1,200 miles north of Capt Scott's objective, and to check the readings made by former expeditions at and near the south pole

The Japanese also are now for the first time entering the field, Lieut Shirhase being expected to start out from Sidney in September There seems to be a general impression among connoisseurs that the Japanese expedition is not properly qualified for successful work,

A German expedition started out from Hamburg in May of this year under the leadership of Dr Filchner and Capt R Vahsel The principal object of this expedition is to determine the relation of the eastern and western antarctic continent and to ascertain whether they are continuous or separated by water A somewhat detailed account of the plans and equipment of this expedition is given in *Die Umschau*, from which our illustrations of the "Deutschland," the vessel which is to carry the explorers, are taken The "Deutschland" was originally built in 1906 as a whaler, and is constructed wholly of wood, as this is found, by virtue of its elasticity, to resist the crushing effect of ice better than a steel hull In fact a steel vessel is apt to be simply cut by the ice, while a wooden craft is pressed up out of the floes The "Deutschland" is rigged as a three-master and carries a 300 horse-power auxiliary engine which in an emergency renders the ship independent of the wind The length over all is 183 7 feet, the beam measures 34 1 feet, and the depth 22 6 feet The tonnage is about 550 The auxiliary engine is capable of developing a speed of seven knots The propeller is two-bladed and can be drawn upon the deck when not in use, so as to protect it from the ice The rudder is similarly arranged to be raised out of the ice,

The greater part of the ship's space is of course taken up by the hold which contains the provisions the drinking water and the supply of coal for the three and one-half years which the expedition is planned to last The general arrangement of the ship's interior is well brought out in one of our illustrations The cost of the expeditions is estimated at $375,000, every cent of which has been contributed from private funds The sledge journey is planned to start from the Weddell Sea (as indicated on our map) The final equipment of the ship for its journey will be made at Buenos Aires where a part of the provisions the automobile sledges Manchurian horses and Eskimo dogs will be taken on board The boat is lighted by electricity, and a powerful wireless telegraph apparatus, which will maintain communication with South America The crew numbers thirty five and the provisions take up 200 tons of the ship's space The plans are laid with characteristic German thoroughness



New Atlantic-type Locomotives for the Anglo-Scottish Expresses

Increasing Use Abroad of Large Boilers and Heavier Loads on Drivers

By Frederick C. Coleman

THE North British Railway Company has this autumn introduced six Atlantic-type locomotives for hauling the Waverley expresses They were built by Messrs Robert Stephenson & Company (Limited), of Darlington, England, to carry a 20-ton adhesion load on each coupled axle, which weight is usually regarded as the limit for British railways An adhesion load of 40 tons in a four-wheel coupled locomotive for Great Britain needs large cylinders, and the dimensions here employed, viz., 20 inches by 28 inches, could not be exceeded without throwing an enormous strain on the steaming capacity of the boiler The long piston-stroke facilitates easy starting, and, with the relatively large cylinder diameter, provides an ample volume for the expansion of steam, so that a low terminal pressure is assured without resorting to compounding The cylinders are carried outside the frames and steam is distributed to them by means of piston valves actuated by Stephenson link motion The cylinders are 6 feet 8½ inches apart between centers, and the pistons are provided with tail rods working in tubular sleeves The main frames are set in at the rear of the bogie to permit of greater side movement on the part of the latter The coupled wheels are 6 feet 9 inches in diameter, the bogie wheels 3 feet 6 inches in diameter and the trailing wheels have their axle boxes carried in outside framing, so that neither the length nor the width of the firebox, which is of the Belpaire type, need be restricted The grate area is 28.5 square feet The boiler has an outside diameter of 5 feet 4⅝ inches and the barrel is 15 feet 4¼ inches long between tube plates Its center is 8 feet 11 inches above the rail level and the working pressure is 200 pounds per square inch

The total heating surface amounts to 2,256 6 square feet The firebox contributes 184 8 square feet, and the tubes, 257 in number, and 2 inches in external diameter, the remaining 2,071 8 square feet The engines are each fitted with combination injectors and lever reversing gear, and are provided with a steam cock with a reducing valve on the tender for carriage-heating purposes Sandboxes have been provided for the leading and driving wheels, the sand being blown on to the rail by air pressure The engines are equipped with standard Westinghouse brakes, and have a vacuum ejector and train pipes, so that they may handle vacuum brake-fitted trains, if necessary The weight empty is 67 tons 2 hundredweight, and in working order 74 tons 15 hundredweight, this last being distributed On the front bogie wheels, 8 tons, on the rear bogie wheels, 8 tons 7 hundredweight, on the four coupled wheels, 40 tons; and on the trailing wheels, 18 tons 8 hundredweight The tender is of the usual six-wheeled pattern and of the standard North British Railway type, and it has a tank capacity of 4,200 gallons of water and 7 tons of coal, the weight in working order being 46 tons 5 hundredweight. In running order, these Atlantics have an aggregate weight on the rails of 121 tons, while the engine length is 38 feet 3½ inch, the total wheel base 27 feet 9½ inches and the length over buffers 63 feet ½ inch

New Atlantic-type locomotive for the Anglo-Scottish expresses.

Engine weight loaded, 74½ tons. Drivers, 6 feet 9 inches diameter. Cylinders, 20 by 28 inches. Heating surface, 2,256.6 square feet.

Three Million Matches a Minute

IT has been estimated that, for each minute of time, the civilized nations of the world strike three million matches This is said to be the average for every minute of the twenty four hours of the day Fifteen hundred billion is the number for the entire year and those persons who live under the American flag are charged with the consumption of one-half of this amount

The importance of the industry which turns out the little splinters of wood tipped with sulphur or some other material ignited by friction, is only recognized when the average smoker tries to contemplate his predicament if he had to go back to the time when he had to coax a spark from a tinder-box Small and insignificant as it is, the match demands as much attention in the choice of the wood involved in its manufacture as any other forest product Only the choicest portions of the best trees are suitable Sap wood knotty or cross grained timber will not do Instead of being a by-product, the little match is turned out at hundreds of mills over the country where the by-products are bulky objects like doors sash, shingles, sidings, posts, and cord woods The pines linden, aspen, white cedar, poplar, birch and willow are the most suitable match timbers

Phases of Science as Other Editors See Them

Instantaneous Roentgen Ray Photography

THE sharpness of Roentgen ray skiagraphs of parts of the body is often impaired by voluntary or involuntary movements of the patient This difficulty would not exist if "instantaneous" or exceedingly short exposures could be substituted for the usual "time" exposures In order to obtain Roentgen rays of sufficient intensity for use in instantaneous exposures, the Roentgen tube must be excited by a single electric wave or pulse, produced by a very large induction coil In the well known Vesta apparatus this result is accomplished by melting a fusible plug in the primary circuit by an overload of direct current

The Erlangen firm of Reimger Gebbert & Schall has recently put upon the market an apparatus in which the single wave or "unipulse" is produced by means of a specially constructed interrupter This device consists of an amalgamated copper rod, surrounded by a closely fitting sheath of insulating material, and dipping into a vessel which contains mercury, covered by alcohol

When the rod is drawn out of the mercury it draws some of the latter after it into the insulating sheath The heat developed in the slender column of mercury by the strong current employed causes the column to break with explosive violence, and drives the mercury downward with great velocity which is increased by the heat of the self-induction spark which immediately follows the rupture of the mercury column The primary circuit is consequently broken with extreme suddenness, independently of the speed with which the rod is raised, and a spark of corresponding intensity passes between the secondary terminals Fig 1 shows the appearance of this spark in ordinary conditions and Fig 2 shows the deformation produced by placing the spark gap in the strongest part of the coil's magnetic field A Roentgen tube excited by this single induced wave, or "unipulse" emits Roentgen rays of sufficient intensity to make strong skiagraphs of thick parts of the body (Fig 3) in 1/200 second

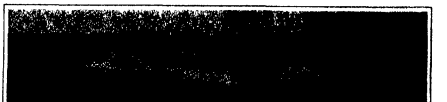
Why Fog Signals Fail

IN a chart published by the United States Weather Bureau, and reproduced here in abridged form, Prof A G McAdie discusses some of the phenomena presented by fogs and the difficulties and dangers which arise therefrom to navigating vessels, especially near shore

The fogs of the Pacific, and especially those on the coast of California, Oregon and Washington, present some characteristic features of their own They are low lying, dense and of frequent and regular occurrence and have been the cause directly and indirectly of a large per cent of marine disasters In the vicinity of San Francisco owing to the general movement of the air from the sea toward the land, and the climate of the great interior valley, fog is frequent and well marked In summer the afternoon sea fog varies in depth from 100 to 1,700 feet, but it rarely reaches far inland On some afternoons the velocity of the wind at San Francisco rises with almost clock-like regularity to about twenty-two miles per hour, and a solid wall of fog, averaging 1,500 feet in height, comes through the Golden Gate, causing a fall in temperature to about that of the sea, namely, 55 deg F The upper level of the fog can be plainly seen from the hills in the vicinity, and it is interesting to note that above the fog level the air is cloudless and the afternoon temperature ranges from 80 deg F to 90 deg F

While the Pacific fogs occur with peculiar regularity, those of the North Atlantic Coast, though at times persistent, are irregular both as to the time of their occurrence and their duration The North Atlantic Coast fogs are probably due to thin strata of warm moist air passing over the cold water surface The summer afternoon sea fogs of the Pacific are also quite different from the winter morning fogs The latter lie low, close to the surface of the water, and do not average more than 100 feet in depth It is nearly always possible, by sending out a look-out, to get above the level of the fog and thus obtain proper bearings With the summer afternoon sea-fogs this is out of the question. The distance which the fog extends seaward is not definitely known, but it is thought that an average would be about 50 miles.



There are instances when a fog has been reported several hundred miles off shore

Whether a fog appears for a few hours at certain seasons, as on the Atlantic Coast, or regularly through the summer afternoons and the winter mornings, as along the Pacific Coast, whether it forms sharply defined streaks and strata, as at San Francisco, or lies in undefined banks, as off Newfoundland, in either case it is due to a cooling of the air and consequent condensation of water vapor The cooling may be brought about by elevation and expansion or by rapid radiation or by mixture with a cooler mass of air or contact with a cooler surface The water vapor condenses on minute nuclei which may be exceedingly fine dust or possibly ions

The morning winter fogs are low lying banks of condensed vapor which, as a rule move from the land seaward and are probably formed by a cooling due to radiation and contact, the land surfaces being much cooler in the early morning hours than the water surfaces, owing to the high specific heat of water The summer afternoon fogs are probably due to cooling caused in part by elevation and expansion and in part by mixing Fogs, as a rule, form when cool air passes over warm, moist surfaces, but in the case of the fogs near the Golden Gate, San Francisco, where the surface temperature is 55 deg F, and the air temperature, at a height of 700 feet, 80 deg. F., condensation is more probably due to a mixing of air currents having different temperatures, humidities and velocities.

A billow on a sea of fog.

Fog surface broken by waves and splashes.

The seemingly unaccountable failure of fog signals at the critical moment has been a source of much perplexity and serious disaster. It not infrequently happens that the master of a vessel will testify that the fog whistle could not be heard, while light-house officials will maintain with equal positiveness that there was no failure to give the proper signal. It is now known that both sides may have been correct in their statements. If sound travels through a medium, such as air, the density of which varies more or less from point to point, it suffers a refraction, or, in other words, the line of propagation is not a straight line. As a result of this it may occur that a sound wave, starting from some point on the surface of the earth, is deflected upward, so that a person stationed at some distance on the surface of the earth will receive no indication of the sound wave, which passes over him, above his head, leaving him unconscious of the disturbance.

Another possible cause through which sound signals may become inaudible at certain points is the reflection of sound from sharply defined clouds or banks of dense fog. Such reflection may have the result that at certain points the direct wave and the reflected wave just neutralize and the sound becomes inaudible

The troubles to which air signals are subject are completely overcome when water is used as the transmitting medium The success of submarine bell signals has been so marked that in time the siren signals through the air will probably become of secondary importance Where both signals can be employed and used simultaneously, a careful determination of the interval between the receipt of the two signals enables the mariner to obtain some indication of his distance from the point of starting of both signals, for obviously the time which elapses between the receipt of the two signals is the difference between the time taken for the air signal and the water signal to reach him. Now the velocity of sound in air is about 1,100 feet per second, in water about 4,700 feet per second. From these data the distances may be computed.

The same principle can be applied with still more satisfaction if one of the signals is given by wireless telegraphy and the other through the water. It is claimed that the bells used as submarine signals can be heard farther, under ordinary conditions, than the siren, and furthermore, by means of a special telephone apparatus, it is possible to determine the direction or the origin of the sound. The receiving apparatus consists of two tanks placed in the hold of the vessel below the water-line. These tanks contain microphones immersed in liquid and connected to the pilot house. An indicator box shows the side on which the responding telephone is connected, and the master is thus able to ascertain the direction from which the signals come.

The Rubber Supply of the Future

THE *Chemical Engineer* publishes an article by Mr Walter Freudenberg of Bremen on the subject of the future rubber supply.

The estimated planted acreages of rubber as given by three of the leading trade publications are as follows: *India Rubber Trades Diary*, 776,000 acres; *India Rubber Journal*, 980,000 acres; *Gummi-Zeitung* (Berlin), 1,310,000 acres; Mr. Freudenberg takes the second estimate as the basis for future yields, and gives the future supply as follows: From Malaya, 70,000 tons; Ceylon, 13,000 tons; Dutch Indies, Borneo, South Mora, and Burma, 20,000 tons; total annual supply of plantation rubber in 1916-17, 109,000 tons. To this must be added the probable supply of wild rubber, which until recently has been about 70,000 tons annually. He considers, however, that the supply from this source may decrease, and estimates only 35,000 tons, making a gross total of 144,000 tons in 1916-17. Statistics show that for the year ending June 30th, 1910, a total of 76,000 tons was used, showing an increase of 5 per cent annually during the past 10 years; if this rate continues, about 107,000 tons would be required by 1916-17.

Results of the Glidden Tour

Lessons to be Learned from the Annual Automobile Endurance Contest

INSTEAD of a distinctly technical contest, such as was held last year, the Glidden tour of 1911 was more of a pleasure event held for the double purpose of emphasizing the good roads movement in the South and at the same time of giving the 1912 models their first practical demonstration. The distance covered this year was only half that covered in 1911, being the 1,454 miles between New York city and Jacksonville, Fla.

The tour started on October 14th and ended October 26th In all some 77 cars were included in the caravan, of which 64 competed. Fourteen, or about 22 per cent, finished with perfect scores, whereas last year, out of 27 contestants, none escaped without penalization. Instead of the rigid technical examination that occurred at the end of the tour last year, the rules this year merely required the reaching of controls on time. The cars were divided into teams of three, the winning team, of course, being the one with the fewest marks. In addition to this, the Chamber of Commerce of Anderson, S. C., donated a $1,000 prize for the car having the best score.

The first few days of the tour were very enjoyable, but the tourists encountered a cloudburst at Roanoke, Va., after which they were obliged to travel through exceedingly muddy roads, as well as to ford streams at several places. That they succeeded in doing the latter with the water almost up to the frames of the cars in some instances, speaks well for the manner in which the carbureters and magnetos are protected in the modern automobile

In our report of the tour last year a warning note was sounded regarding that most important part of the car—the steering gear The breaking of steering knuckles or the failure of other parts of this gear were in 1910 of much too frequent occurrence This year but one such accident was reported, but that, unfortunately, was a fatal one On the day before the tour ended the pacemaking car of J P Walker, in which the owner, his wife, and S. M Butler, chairman of the Contest Board of the A A A., were riding as passengers, ran off the road into a field and upset when going at high speed The chauffeur escaped unhurt, but Mr. and Mrs Walker were both severely injured, and Mr. Butler was crushed beneath the car and killed. The accident, which occurred at Tifton, Ga., after the 42-mile run from Cordele had been made in an hour, was caused either by the steering gear giving way or from the car becoming unmanageable when driven at high speed through deep sand The chauffeur claimed the former was the case There was a great deal of racing throughout the tour, and it is a wonder that there were no other serious accidents.

The winning teams, with the points charged against them, were as follows

1	Tarrytown (3 Maxwells)	0
2	Atlanta No 2 (3 Stevens-Duryeas)	19
3	Jacksonville (3 Cadillacs)	28
4	Atlanta No 3 (3 Fords)	125
5	Live Oak (3 Cadillacs)	279
6	Nashville (3 Marathons)	509

The fourteen cars which had perfect scores were made up as follows 4 Maxwells, 3 Cadillacs, 2 Stevens-Duryeas, 2 Fords, a Columbia, a Mitchell, and a Flanders

The winner of the Anderson trophy, who was picked by lot, was Governor Hoke Smith, of Georgia, with his Maxwell Miss Roberta Marks, of Athens, Ga., was the only lady driver She piloted her silver-plated Columbia, filled with several lady friends, through to the finish with a perfect score

The fact that 11 of the 14 perfect-score cars were low-priced machines shows that the modern light-weight touring car, which can be bought for about $1,000 is, if anything, more dependable than a heavy high-priced machine, especially when it comes to traveling at high speed over rough and muddy roads Under such conditions the light car has the advantage in every way, and to make it all the better, it is the cheapest to buy and to run

Science

Stamp-vending Machines in the German Postal Service.—Automatic machines for selling postage stamps are now extensively used in German post-offices, and have effected a considerable saving in the postal administration, although convenience to the public was the prime motive for their introduction. Nearly 50,000,000 stamps were supplied by the machines during the past year, their value aggregating about $750,000

Surfacing Concrete Electric Light Poles With Mica.—Ground mica is now being used extensively for surfacing concrete in cement work. It has proved very effective for this purpose as it gives an artistic finish to the work, and adds life and sparkle to the surface, taking away that flat, dead appearance that is common to concrete. About five pounds of mica is sufficient to cover 100 square feet. The electric light columns in Lincoln Park, Chicago, were treated in this way Crushed red granite was used with the mica, so that the finished surface has the appearance of polished granite. The granite and mica surfacing material was applied to the inner surface of the square iron trough in which that part of the columns that was to extend above ground was cast When the trough was filled, the top or lid was screwed down, crowding the concrete into all the lines and corners of the mold After the cement had set perfectly, part of the mold was removed to permit the post to cure more rapidly The post was not removed from the mold until it had set for 24 hours at least. After it was perfectly dry the surface was scrubbed with muriatic acid, to remove the cement on the outer face of the granite and mica and leave a clean surface closely resembling that of granite.

An Imperial Chinese Printery.—A few months ago the Chinese government began to erect a modern printery that will require a total expense of $2,000,000. Construction of the building and installation of the printing-plant have been intrusted to American architects The present monetary system of China is so complicated that it is really a very emphatic hindrance to the development of trade and industry In accordance with this system every individual province emits its own currency, and the standard of value is different in every province. For a long time, consequently, a persistent effort has been made to devise and introduce a uniform standard of value for the whole empire, and the construction of the printery in Pekin begins the transformation of the collective monetary system of China. Two years ago the government sent Dr. Chen to Europe and America to study the machinery, and its installation, of the most efficient printeries in these countries, and in accordance with his report the governmental printery of the United States in Washington was selected as a model. It is hoped that the Imperial Chinese Printery may be finished within two years so that it can begin work when Parliament opens in 1913. Besides other experts two American engravers have been employed already to supervise the installation of the plant and to instruct the Chinese in the art of engraving.

Engineering

Our Excellent Lighthouse Service.—It is a curious anomaly that the United States, which possesses the smallest foreign-going merchant marine in the world should possess the most perfectly-equipped and elaborate lighthouse service to be found on the coast line of any nation During the past half century this service has cost $150,000,000, and its maintenance calls for the appropriation of about $7,000,000 annually

Panama Exposition Memorial Tower.—A concrete steel tower, which will be the loftiest structure, with the exception of the Eiffel Tower, in existence, is to be erected at San Francisco in connection with the Panama-Pacific International Exposition, which will be held in that city in 1915 From the floor to the top of the figure of Victory, surmounting the shaft, the height will be 850 feet It is to consist of a square shaft upon a base 232 feet square and 120 feet high The shaft will measure 85 feet on each face The estimated cost of the structure is $1,500,000

Daily Earnings of a Locomotive.—A writer in the *Railway and Engineering Review* recently gave the interesting results of a computation of the average daily earning capacity of the American locomotive The estimate took account of time spent in the repair shop, increased cost of repairs and renewals, and the cost of fuel, water and the engine crew The average earnings per locomotive per day in the East are $124.84, and on the western roads, $130 84 The highest earnings in the West are those of the Santa Fe locomotives, which work out at $149 53 per day The highest earnings in the East are on the Central Railroad of New Jersey, where the average is $147 06 per day.

Steam Turbine Improvements.—The superiority of the reciprocating engine over the steam turbine when a ship is steaming at low speed is destined to disappear. At high speed the turbine possesses every advantage; but at low speed it is extravagant in its use of steam. Of the several systems of reduction gear by which the widely different economical speeds of propeller and turbine are sought to be harmonized, the electric drive seems to present the most promise A better method would be the proper combination of reciprocating engines for low speed and turbines for high speed. The navy has under consideration a system of this kind which we hope shortly to present for the consideration of our readers

Our New Three-gun-turret Battleships.—Plans and specifications are now being prepared in the Navy Department for the two super-dreadnought battleships authorized at the last session of Congress These ships, which will be named the "Oklahoma" and "Nevada," will contain many novel features, the most important of which will be the introduction of the three-gun turret, of which there will be two, containing six 14-inch guns. The other four 14-inch guns will be carried in two-gun turrets. The armor plan has been worked out with great care; and we understand that these ships will be protected by a thickness of face-hardened armor which has never been attempted in any battleship in our own or foreign navies

Aeronautics

Results of the Tests for Military Aeroplanes in France.—The preliminary tests of the 29 machines entered in the competition for military aeroplanes in France have resulted in the elimination of 5 of the 8 monoplanes and 14 of the 19 biplanes Neither of the two triplanes—the Astra and the Paulhan—was selected The machines which were scheduled to participate in the final 185 mile speed race on November 4th were the Morane, Nieuport and Deperdussin monoplanes, and the Breguet, Savary, H Farman, and M. Farman biplanes We expect to publish a complete account of these tests in our next issue

The Trans-continental Flight Nearly Completed.—On November 1st Aviator Calbraith P Rodgers covered 177 miles between Wilcox and Maricopa Ariz., and got within 400 miles of the coast At Tucson, the half way point, he met Robert G Fowler who arrived there October 30th on his flight from the Pacific to the Atlantic, and who was delayed with engine trouble and an accident upon restarting The two dauntless Wright pilots shook hands, congratulated each other, and hoped for better luck Rodgers found a number of broken rollers on the propeller chains of his biplane, and was delayed at the start in replacing them Then he had to breast a 30-mile head wind and to climb considerably to get through the 4,351-foot Dragoon Pass. He fought a head wind throughout the entire day, his time *en route* being 1¾ and just over 2 hours, respectively November 2nd he flew 35 miles to Phoenix in 35 minutes, and 105 miles to Stovall in 118 minutes, aided by a strong wind He beat his special train by over two hours

Recent Aeroplane Fatalities.—The last month has witnessed the passing of the hundred mark in aeroplane fatalities October 12th aviator Level fell to his death in a Savary biplane which he was piloting in the French army tests His spine was broken and he died soon after Two other French aviators—Horta and Germain—also fell the day previous One was killed and the other fatally injured The hundredth victim of aviation was Hans Schmidt, who fell at Berne, Switzerland, on October 14th, and was incinerated as a result of the ignition of his fuel On the 21st ult an aviator named Tacks fell and was killed near Hamburg The loss which was most keenly felt in America, however, was occasioned by the death of Eugene Ely, the Curtiss aviator, at Macon, Ga., on October 18th Ely was making one of those daring dips for which Hamilton became famous when he miscalculated and struck the ground with terrific force He was thrown out and his neck was broken Ely was using a machine without any front control, while he had been used to a biplane with a front horizontal rudder The slower response of the former type to a movement of the elevator was doubtless responsible for Ely's death, although the immediate cause was the performing of foolhardy tricks On October 27th Jean Desparmet fell 600 feet in a 100 horse-power Blériot military monoplane at Rheims while on the 31st Prof. John J Montgomery was killed in California.

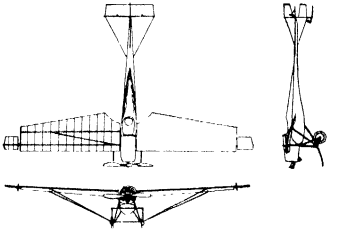
New Development in Aeroplane Construction

Three European Types Embodying Unusual Features

By Grover Cleveland Loening

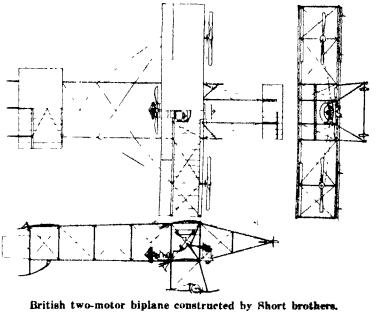
QUITE recently there have been brought out in Europe several radical types of aeroplanes characterized by novel departures from accepted practice, and by far the most interesting ones are the new Antoinette, the Pivot, and the Short "twin" engine biplane.

Up to a few months ago, the aviation industry as a whole exhibited work of much ingenuity and cleverness but was wofully lacking in those fine points of pure engineering that go to make any field of applied science a successful one. With the new types that have been developed abroad, however, it appears that thoughtless copying of a few successful "experiments" is giving way to a more detailed and careful study of the countless different conditions occurring in the practice of flying upon which designs with definite ends in view are being perfected. The Breguet biplane and the Nieuport monoplanes may truly be said to represent the pioneer stage of aeronautical engineering, representing as they did, a much higher state of development than any other types. But in France, especially, progress is rapid and it is almost safe to predict that in a short time the Nieuport will be out of date. Many weak features in this type have already been discerned, notably the shape of the body and the landing chassis. At any rate, about the most hopeful sign yet exhibited in the progress of the flying industry is the design and development of aeroplanes with other ends in view than the mere ability to fly and to land without collapsing. Ease of packing for shipment and speed in erection and "tuning up" are factors of great importance that are receiving careful consideration. Many dispositions likely to add to safety and a reduction in the number of parts with a view to simplifying and cheapening manufacture are being developed. So it may fairly be said that we are beginning to emerge from the embryo state of aviation to one that is likely to hasten the advent of its full commercialization.



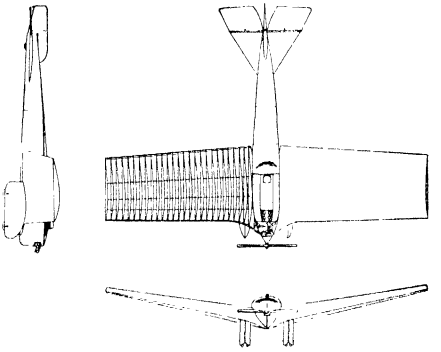
Each one of the types described here bears one or more distinguishing features and they have been admirably adapted in practice to the work for which they were designed.

The Antoinette Monoplane.

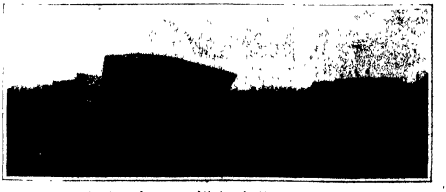


The new Antoinette monoplane, designed especially to take part in the French Military Competition, has an unusually radical appearance. This machine, primarily intended for military purposes is equipped with armor plate protection about vulnerable parts like the motor and chassis, but its most important feature is the total elimination of cross wires, struts and the like. All parts are inclosed—even the wheels and skids—with the result that the resistance is greatly decreased, but the weight increased. In addition a peculiar wing section is used, flat on the under side and curved on the upper side. This type of wing section as learned from aerodynamical experiments has a very bad drift resistance at low angles and a very uniform rate of change of the ratio of lift to drift at low angles. The center of pressure as the angle of incidence decreases below 10 degrees does not move back as rapidly as on other shapes. This type of wing is therefore more stable and of smaller resistance. The distribution of pressure, however, is very uneven, but because of the great strength of the planes themselves at all points, this is not a detrimental feature.

The wings are immensely thick being entirely braced from the inside. At the body the wings are over two feet thick, something altogether without precedent in aviation. Their thickness decreases toward the tips which are about 8 inches thick. The shape of each wing is trapezoidal, and they are at a large dihedral angle. This adds to the stability in a calm, in a gusty wind conditions arise where a large dihedral angle is thought by many to be dangerous.



The boat-like body of this new type is entirely inclosed and is capacious to say the least. At the front is the motor, the aviator sits in the body between the two wings, and at the rear are the rudders. The body has a stream line form, and a splendidly shaped prow.



Drawings of Pivot monoplane with ailerons.

British two-motor biplane constructed by Short brothers.

Plan and elevations of "armored" Antoinette monoplane.

Side view of "armored" Antoinette war aeroplane.

A two-bladed Normale propeller at the front pulls the machine forward. The motor is a regular 100-horse-power Antoinette, but the machine will fly with a 60-horse-power motor.

The oddest feature of this type is the landing gear, which is entirely inclosed to within a few inches of the ground, the landing wheels at the front are six in number, three on each side of the center, inclosed in what is called a "skirt." At the rear are two smaller wheels.

The dimensions are roughly as follows. Spread, 52½ feet, area of supporting surface, 602 square feet, length over all, 36 feet; width of wings at tips, over 9 feet, increasing to almost 13 feet at the center. The total weight, including fuel and operator, is nearly 2,400 pounds.

The aviator obtains a view beneath him through a glass floor under his seat. For the reduction of resistance, even the exhaust pipes of the engine are inclosed in a stream line shield.

This type is certainly birdlike in its appearance and immense in size, but whether the great sacrifices made to eliminate projecting spars or wires are wise remains to be seen. For a purely speed machine it would be wise, without a doubt. There is a large expanse of vertical surface in this machine which is likely to make it difficult to handle, especially in a wind. A number of successful flights have already been made, however.

The Short Biplane.

An aeroplane, equipped with two motors, which has already completed duration flights of over an hour and is therefore capable of fulfilling the conditions of the Gould Prize, has been built in England by Short brothers.

In general outline it is a biplane of the 1910 Farman type, equipped with two 50-horse-power Gnome engines placed centrally one in front of and the other in the rear of the lower main plane at either end of a nacelle or inclosed body. The front motor drives two propellers by chains in opposite directions, precisely as on the Wright biplanes. The propellers are of high pitch, shaped like Wright propellers, but are at the front of the main cell. The rear motor drives a single low pitch propeller at high speed, as on the usual Farman type.

It is possible to operate either motor separately or both together. The entire mechanism has worked to the utmost satisfaction, its feasibility being proved beyond a doubt.

The aviator sits in the nacelle, a passenger seat at his side. The rudder and aileron controls are of the usual Farman type.

The landing chassis and in fact all details of construction are very strong.

With the immense extra power available—one motor alone sufficing for ordinary flight—this type has the ability to go fast or slow, and, in addition, on occasion can climb with great rapidity, with its full 100 horse-power. It is to be noted that the axes of the front propellers and the rear one are not on the same level. This is designed to counterbalance the effect on the tail, had by the draft from the rear propeller. As soon as the latter ceases to operate the lifting tail sinks, but the higher position of the axis of thrust of the front propellers at once overcomes this.

The dimensions are as follows: Spread, 34 feet; chord, 6½ feet; supporting area, 435 square feet; weight in flight, 2,000 pounds. The speeds are said to vary from 35 to over 50 miles an hour, depending on the amount of power used.

The Pivot Monoplane.

A highly interesting monoplane has recently been brought out in France, known as the Pivot. Its distinguishing features are the use of ailerons for

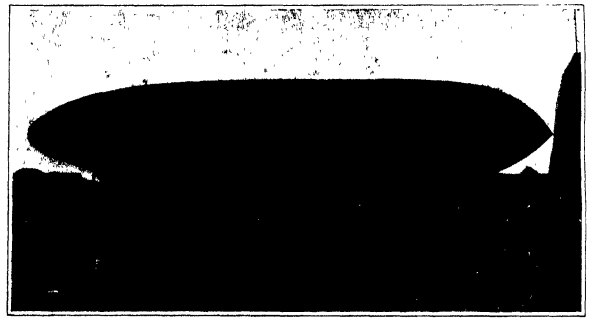
NOVEL FOREIGN AEROPLANES

verse control and the manner in which the planes are braced.

The body, of stream line form, suggests a combination of the Deperdussin and Breguet. The motor is at the front covered by a well designed hood. The pilot is comfortably seated at the rear of the main planes which are notched to enable him to have a clear view. The span of the planes is 34½ feet and their area 274 square feet. The weight of the machine is about 600 pounds in flight. A 45-horse-power Rossel-Peugeot motor is used. The wing section is of the now familiar Nieuport type, the wedge-shaped entering edge, however, being noticeably larger, and the reverse curvature at the rear somewhat sharper.

For some time, many engineers have been awaiting the monoplane that should cease to have its planes braced by wires—tension members—above the planes, where they never receive any tensile stress except upon landing. As soon as the machine takes to the air with the full pressure acting on the surfaces, the wires above the plane are relieved of all stress and must in consequence hang more or less loosely, thus generating a considerable resistance. It is recognized, however, that in gusty weather, reversals of stress are likely to take place and tension members alone on the under side of the planes would not suffice. There are two ways, however, in which monoplanes can be efficiently braced with the fewest parts and least resistance. The first way is to have compression members alone, capable of taking tension as well above the planes, and the other is to have tension members capable of taking some compression without undue bending below the planes. It is this latter method that is used on the Pivot two steel tubes below each plane alone suffice to brace it solidly to the chassis. The results so far have shown this to be an excellent provision, no other bracing wires being necessary. Another novel feature is the use of ailerons instead of warping.

Preparations for Launching the "Akron" for Its Trial Trip



Preliminaries for a More Complete Test

THE announcement was made on October 26th that Mr. Vaniman might, on the next Saturday, make a trial trip with his airship "Akron," familiar to our readers as the craft that is to carry its captain and crew across the Atlantic some time this autumn. While the public has been disappointed so far as the trial trip is concerned, which, at the time of writing, has not yet taken place, the preparations for the trip and the attempt which was made to start out on it, were in themselves of sufficient interest to deserve brief mention in these pages.

Early in the afternoon of Sunday, October 29th, Mr. Vaniman began to make preparations to lead his giant airship out of the shed and, if possible, to make a trial flight. The weather conditions were very favorable, though there was a slight wind blowing, sufficient to call for caution in the handling of the dirigible as it emerged from the shed. A large crowd had assembled in front of the hangar, its front ranks forming a semi-circle around the rope that had been put up to fence off the public from the space allowed for the launching of the airship. The preparations consumed a good part of the afternoon, but finally the "curtains" that form the door of the shed were drawn aside and, loudly cheered by the crowd of people, the leather-colored envelope of the "Akron" began to thrust its rear out of the shed, as a gang of about one hundred men, holding on to the anchoring wires and to the keel of the car, slowly moved the airship out into the open. Even to those who had become quite familiar with the aspect of the balloon by frequent visits to the shed, which was open to the public for a small fee, it was an imposing sight now to see the great craft fully disclosed to broad daylight, with the view unobstructed and the airship out in the open, apparently ready to be launched. This was the first time that the balloon had left the shed, and the men handling it were largely new to the work, so that it was an experiment of some interest. In spite of a wind that was not by any means negligible, the operation was performed perfectly and without a hitch. About two-thirds of the men holding the balloon were firemen and policemen of the Atlantic City force, the remaining one-third being made up of the regular workmen.

No attempt was made on this occasion to make a flight or even to run the engines, but the dirigible was simply led back into the shed just as it had been brought out, and with the same success.

It will be recalled that the airship carries two sets of propellers—one with fixed axes and the other revolvable in such a manner that the propellers can be made to exert their thrust in any desired direction. The first set of propellers and its engine seemed to work satisfactorily, but the right-hand propeller of the second set gave much trouble, its bearings giving out repeatedly whenever the engine was tried. The mechanics were kept busy upon this propeller, the work being carried on deep into the night, and by the next morning, Monday, the indications were that an actual trial would be made that afternoon. As is not unusual in such cases, numberless little complications arose, which delayed the work, so that by the time the balloon was ready once more to be taken out of the shed, it was rather late in the afternoon. The engines were tried in the shed and seemed to work well. The crew and several passengers got on board, and Mr. Vaniman gave the word for the 'Akron" to be slowly drawn out. The operation was performed with the same success as on the previous day, the balloon being slightly turned so as to point into the wind. The attempt to start the main engine from the auxiliary engine, however, proved futile. It appears that a pin in the clutch lever had given out and it was found impossible to repair the damage at short notice. Thus a seemingly trifling cause rendered the flight that afternoon impossible, and with considerable disappointment the crowd presently saw the balloon once more retreating into its hangar as dusk began to fall.

Copyright 1911, by Harper Smith

Airship "Akron" in which Mr. Vaniman expects to cross the Atlantic.

While to those who were expecting to see the airship ascend, the performances of Sunday and Monday must have been disappointing, yet they were really very instructive and interesting. When we consider the great number of little points that require attention, and are liable to go wrong, the wonder is not that these first trials failed to give immediate success, but that it is at all possible to get the entire equipment of the airship under such complete control that it can be relied upon at any instant during an extended flight, a condition which evidently must be most rigidly satisfied for the proposed trans-Atlantic trip.

It is with the greatest interest that we shall follow the accounts of further trials which will precede the actual journey. The time of the year is advancing, and it is to be hoped that successful trial trips will be made within a short time, so that the actual journey may be started before the favorable season of the year closes.

Foreign Accent Marks

A LEADING theatrical company recently toured the United States playing Sardou's "Divorçons." Throughout the country the billboards announcing the event printed the name of the play, in letters a foot high, "Divorcons." This word, written with the right kind of a ç, is French, pure and simple. It admits of no anglicization. As transmogrified by the American printer, it is neither French, English, nor Swahili. As the second syllable, thus printed, rhymes with *pork*, it may be Chicagoese.

Cure is a land of paradoxes, one of the most striking of which is the fact that a people largely recruited from continental Europe should have come to the conclusion that the accent marks used in their various mother tongues are superfluous appendages—mere ornaments, like the paper frills of a French chop. Nothing could be farther from the truth. The European languages, except English, follow the common-sense plan of writing a word as they intend it to be pronounced. Before certain vowels the sound of *c*, in French, bears no resemblance to that of ç. They are, in fact, different letters. *Conde* does not rhyme with *Fronde*. In German, *u* is the modern method of writing the diphthong *ue*. When Herr Muller accepts American citizenship as Muller, he is simply repudiating his family. Better call himself Miller and be done with it. Max Müller was still Müller after fifty years in England, and we are glad to observe Hugo Münsterberg correctly spelled in "Who's Who in America" and other dignified literature. Not so, however, in the American newspapers.

A few years ago an international scientific congress met in Washington, and the local papers paid the foreign visitors the delicate attention of printing their proceedings in what was intended to be French. The result was amazing. Columns of a hybrid language appeared, containing not a single accent. Expostulation with the editors was met with the explanation that the typesetting machines had no accents on their keyboards. Why under these circumstances, the newspapers attempted the job possible was not explained.

The daily press both directs and reflects popular usage. It would be difficult to decide whether the newspapers or the public should be held responsible for the obsolescence of the foreign accent in America.

A painstaking examination of the practice prevailing in such matters reveals the startling fact that only one French word is now generally supposed in this country, to require an accent. This is the word *buffet*. This euphemism for a public bar has become popular in America during the past decade. The word greets us at every street corner always duly provided with an accent. The kind of accent, as well as its position, is a matter of individual taste. We have seen *buffet*, *buffit*, *buffét*—and even *baffit*.

Are there any readers of this journal who need to be told that *buffet* is accentless in French?

Frequency of Electric Oscillations Proceeding from a Spark

THE luminous track of a short electric spark owes its presence to variations in field intensity due to the capacity of the electrodes and the ionization of the air. As a matter of fact it is well known that the spark is oscillatory in character. By blowing a steady current of air through the spark formed a horn electrodes, M. C. Caudrelier, as reported by *Cosmos*, has succeeded in separating the successive tracks of the oscillatory spark by several millimeters, knowing the velocity of the air (20 meters per second) and the distance apart of the individual spark tracks (2 millimeters), it is possible to measure the frequency of the oscillations. In this way it has been found to be of the order of 10,000 periods per second.

A Landsman's Log Aboard the Battleship "North Dakota"—II.

By J. Bernard Walker.

This Landsman's Log is written by the Editor of the SCIENTIFIC AMERICAN as a preliminary to a magazine Naval Number to appear December 9th, which will be comparable in its size and completeness with the Naval Number issued during the Spanish War. In one respect it will be unique, for it will contain a signed message from President Taft, and will be written entirely by prominent officers of the Navy, each a specialist in the particular field that he covers. The leading articles, moreover, will be from the pen of the Hon. George von L. Meyer, the Secretary of the Navy. The illustrations will consist of special photographs taken during the recent maneuvers and target practice of the Atlantic Fleet on the Southern Drill Grounds.

THAT ever-memorable two weeks' cruise with the Atlantic fleet was full of the unexpected and surprising. Returning late one afternoon from witnessing aerial target practice aboard the "Michigan" (of which more anon) I entered my stateroom to find it in a condition of weird disorder. The bureau had been pulled away from the wall, and its glass taken out, wrapped in a blanket and laid on the floor. Beside it, upside down, was the wash-bowl, while the water pitcher had been put to bed in my berth, where it reposed in comical gravity, upon the pillow. On the bedding lay also, a heterogeneous collection of bottles, pictures, electric light fixtures, and even the electric fan. "Rough house" on board the "North Dakota"? Impossible! "Hazing"? Yes, to be sure—hazing the landsman. What more natural and appropriate? Had I not, when crossing the line, seen Old Neptune come aboard, when the luckless landlubber was bedaubed and gently scraped with a barrel stave? So, chuckling over the fun of it all, I went to the wardroom mess, and saw, would you believe it? the piano slung from the ceiling by a couple of stout ropes, and looking even more grotesque than my tornado-stricken stateroom!

Had the good ship's company gone crazy, or had I? Neither the one nor the other, gentle reader. This was merely a very necessary preparation for target practice by our battery of fourteen 5-inch rapid-fire guns, for the discharge of even these relatively small pieces so jars the ship, that any glass or porcelain that was held rigidly in place would be shattered. Even the strings of the piano would snap.

At mess I got the full particulars. The "North Dakota" had fought a terrific battle during the day in which she had been pretty badly knocked to pieces. Big guns disabled—shot holes at the waterline—a compartment flooded—one smokestack gone, the other riddled—speed reduced, and all the other etceteras of damage by shell fire. It had been a drawn battle, but the adjoining coasts of the enemy were swarming with destroyers, and they would undoubtedly be sent in among our crippled ships for a night attack.

And so, when the mess tables had been stowed, the "North Dakota" weighed anchor, and, with lights out, slid silently away from the fleet into the night. No one knew where the enemy might be, or from what quarter the dreaded destroyers might rush at us out of the blackness. It was for us to find him, and pour such a hail of high explosive shells upon the oncoming craft, that they would be disabled or sunk before they could get within range, round to, and start the dreaded Whiteheads upon their fatal run. I went on deck and climbed onto the roof of No. 3 turret, which I found to be crowded, as were the roofs of the other turrets, with sailors (chiefly the turret crews) who had taken this point of vantage to watch the attack.

Suddenly there came a crackling and spluttering from the top of the search-light towers, and half a dozen beams of light stretched their long, ghostly fingers out into the murk. To and fro, far and near over the ink-black waters, they swept, while the great ship, silent, tremorless and dark, forged slowly ahead. It was a tense quarter of an hour, and just as one felt a touch of impatience, there shone out, some 2,000 to 3,000 yards distant, a moving target, looking whiter even than the search-light beams. The target consisted of four squares of gray canvas on a ground of lighter hue, each square the size of a destroyer approaching head-on.

And then comes a flash, more blinding than any lightning stroke, and the crash of an explosion, more wicked and penetrating than the loudest snap of any artillery of the heavens! And see that beautiful, slightly-curving streak of phosphorescence, heading straight for the first square patch. That is the smoke of the shell "tracer." The tracer is a small plug containing combustible material, which is inserted into the base of the shell. It is ignited at the instant of discharge, and throws to the rear a dense trail of smoke, which serves to show the path of the projectile, and assist the spotter and sight-setter in making the necessary corrections for the next shot. The 50-caliber 5-inch rapid-fire gun is a superb little weapon. The shells leave the muzzle with the high velocity of 3,000 feet per second. Consequently the trajectory is very flat, and the moment the blinding flash of the discharge is out of one's eyes, it is possible to see a little phosphorescent spot rise slightly above, and then curve down to the distant target. It curves so slightly that the 2,000 yards seems to be almost a point-blank range. Then comes the splash and the ricochet—the last-named, because of the high velocity, reaching a great height, sometimes curving upward a thousand yards or more into the heavens.

"And then comes a flash, more blinding than any lightning stroke, and the crash of an explosion, more wicked and penetrating than any artillery of the heavens! And see that beautiful, slightly-curving streak of phosphorescence, heading straight for the first square patch. That is the smoke of the shell 'tracer.'"

REPELLING A TORPEDO NIGHT ATTACK

In all target and battle practice, the time element, as well as the accuracy, is taken into account, in determining the relative excellence of the work done by the various guns. Hence, the report of the guns came in rapid succession; and often it was possible to see several shells in the air at the same time, one or two between gun and target, and several others—earlier shots—completing their ricochets in a series of vast sweeping curves extending miles beyond the target, the shells bounding over the black waters like a series of luminescent tennis balls.

Commanding forward, with No. 1, each battery in turn fired its quota of rounds. The guns roared and roared down the line until No. 14, the last on the port side, had let go its last shell. The "North Dakota" then headed for the target, to learn what kind of shooting she had done, and sent a boat over to

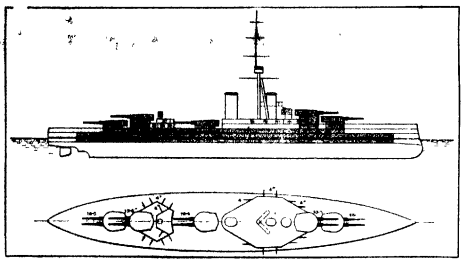
remove the shattered squares of canvas and put fresh ones in their place for the next run, with starboard batteries engaged.

Acting gladly on the suggestion that I should now stand in one of the gun casemates and witness at close range the work of the gun crew, I chose battery No 13, the aftermost battery on the starboard side. The casemate port is cut away to allow the gun to be trained dead astern; and the great width of the opening, coupled with the fact that this gun carries no shield, affords a large field of view for watching the course of the shells. What I saw, our artist has endeavored to depict in the accompanying engraving It should be understood that only a part of the gun crew is shown. As a matter of fact, in addition to the officer in charge, there are ten men to each gun First, the gun captain, in charge of the crew, who opens and closes the breech Second, the pointer, who stands to the right of the gun, on a platform attached to and moving with the gun mount This man, by means of a handwheel, elevates and depresses the piece, keeping the horizontal wire of the telescopic sight upon the target. He also fires the gun by trigger, closing an electric circuit. Third, the trainer, who stands on a similar platform to the left of the gun. His duty is to keep the vertical wire of the telescope upon the target, which he does by means of a handwheel that trains the gun to right or left. Fourth, the sight-setter, with telephone head-piece in place, who stands to the rear of the trainer, and by means of a graduated disk and cylinder, sets the sights according to directions as to elevation and deflection, telephoned to him by the spotter, who is watching the fall of the shots from some elevated position on the ship. Fifth, the loader Sixth, the primer man, who inserts the primer the instant the breech is closed. Seventh and eighth are the first and second powder man; and ninth and tenth are the first and second shell man. The battery here shown was manned by a detachment of the marines, of which most efficient corps, 66 men and two officers, a captain and a lieutenant, are to be found on each first-class ship

As I entered the casemate, No 2 battery on the port side commenced firing, and battery after battery roared and flashed down the ship's broadside I noted that to the right of the gun and to the rear of the group of men stood a row of copper cases, each containing its charge of powder neatly sewed up in a canvas bag On the opposite side of the crew was a row of sharp-nosed 6-inch shells. As the din of the firing comes nearer, there rings out the sharp command to "load" Instantly, with one swing of the lever, the gun captain opens the breech, the shell man thrusts home a shell, and the powder man the powder charge With another swift swing of his arm the gun captain brings over the breech block, which is slammed into place and locked Meanwhile the powder men, shell men and primer man have picked up their respective pieces, and stand ready for the next loading. Months of training have developed the gun crew to a point at which (were it desirable) the gun could be fired at the rate of twenty shots every minute

And now the heavy jar of the ship, the blinding flash and curiously stunning effect of the discharges, tell us that No. 11 gun in the next casemate is engaged The tension increases until it is almost a pain, the crew stand as alert as a football team waiting for the pass of the ball! Pointer and trainer, each with eye to the telescope and shoulder crowded firmly against the gun sleeve, are ceaselessly rocking the handwheels to and fro as they keep the wires upon the distant gray patch upon the target "Fire!" comes the command—the steel floor of the casemate shudders, there is a flash that seems to burn the very eyes out of their sockets, and a curious suffocating sensation at throat or chest, and I am peering eagerly through the casemate opening to watch that little magic phosphorescent pencil point trace its tell-tale path to the target Nine times in succession comes that amazing burst of flame and ear-splitting crash—and the night firing for 1911 is over

Later, and long past the midnight hour, the canvas targets, each rolled up on its battens, are brought aboard the quarter deck to be inspected by the ordnance officer and the umpires One of the searchlights is turned down upon the deck, and one by one the targets are unrolled and the shot holes counted Ordinarily the sailors turn in early—but not to-night Massed around the targets, crowding the rail on one side and the 12-inch turrets on the other, they watch the count, looking eagerly for those little jagged holes in the cloth which tell of the passage of the shells Less demonstrative, but no less eager, is the interest of the officers—and when it was told that 98 hits out of 120 rounds had been made, and the "Delaware's" score of the previous night had been beaten, the enthusiasm of that ship's company was as that of the grandstand and bleachers, when the home team has come out ahead in a championship struggle.

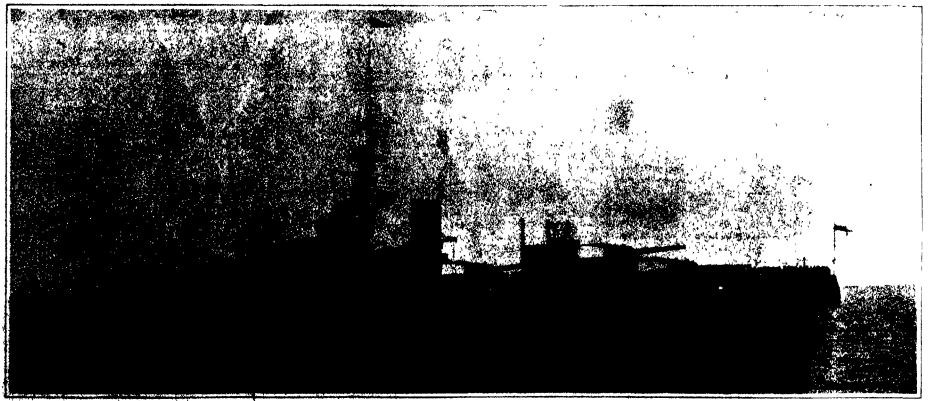


(To be continued)

The Battleship "Orion"

The First British Super-Dreadnought

By Percival A. Hislam



THERE are many points of interest to be noted in connection with the completion of the British battleship "Orion," which, having completed her trials, is now being prepared for commission. In the first place, the "Orion" is the first completed vessel to mount the new 13.5-inch 76-ton gun. Secondly, she is the first British ship of the all-big-gun type to carry her five turrets on the middle line Thirdly, she is the first British armored ship to exceed a tonnage of 20,000 The figure has been reached and closely approached before. Thus, the "Neptune" displaces 19,900, and the "Hercules" and "Colossus" 20,000 tons The tonnage of the "Orion" is, however, 22,500, which is still slightly below the displacement of the German battleships "Helgoland," "Thüringen," and "Ostfriesland," now in service with the High Sea Fleet

Outboard profile and deck plan of "Orion," showing disposition of guns and armor.

The "Orion" left for her preliminary trials on September 11th, twenty-one and a half months from the laying of the first keel plate No single detail of the vessel has been officially published but the following are her principal dimensions Length (between perpendiculars), 545 feet, length over all 584 feet, beam, 88 feet 6 inches, mean draft, 27 feet 6 inches The machinery is of the Parsons turbine type the designed horse-power being 27,000 for 21 knots On the full speed trial the contract speed was exceeded by a knot It is interesting in this connection to note that of the eleven completed British dreadnoughts only two have failed to make 22 knots, namely, the "St Vin-

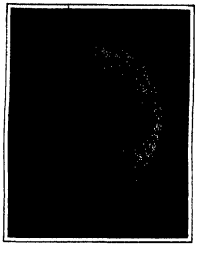
(Concluded on page 438)

Displacement, 22,500 tons. Speed, 21 knots. Armor: Belt 12 inch, turrets 12-inch. Armament: Ten 13.5 inch and twenty 4-inch guns

British battleship "Orion"—first of the super-dreadnoughts.

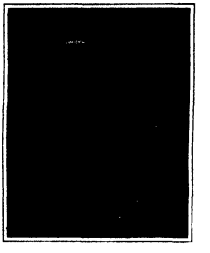
Simple Tests for Food Purity

What the Housewife May Do to Detect Adulterations



By S. Leonard Bastin

FROM time immemorial the freshness or otherwise of an egg has been a perplexing problem to the housewife. Even at the present time it is probable that the majority of people do not know how to tell whether an egg is good enough until they have broken it. This is strange inasmuch as the method of finding out the condition of eggs is so simple that anyone can follow it, moreover, the test given is one which is relied upon by the trade and may therefore be taken with confidence. All that is necessary in order to carry out the experiment is a dark room in which a candle has been placed. Now take the egg and hold it up between the eye and the light. A new-laid or very fresh egg will show clearly an air space in the larger end between the shell and the lining membrane. If the egg is really new laid this should be very small, for it tends to increase as an egg is kept. All the rest of the surface shown should present a homogeneous and translucent appearance, if the article is positively bad a number of dark spots will be visible. A glance at the accompanying photographs will readily give an idea of the two qualities. Once the test has been performed there is no reason why anyone should ever be taken in over the egg question. There is little doubt that milk, especially in towns, is still subject to the time-worn practice of adulteration with water. If skillfully done this is not very easy to detect if the mere appearance of the liquid is considered. There is one very simple test which will tell us at once whether the milk is of a good quality and rich with a proper amount of cream. Take a sample of the milk and place it aside in a receptacle, a small tube is good for the purpose. Stir the milk well and then take a thick bright knitting needle. Plunge this to a depth of several inches into the milk and hold it steadily slanting downward. If the milk is of a rich quality the fluid will slowly gather in a drop at the end of the needle and this will remain, for rather a long time. On the other hand, supposing water has been added the drop will hardly form at all, and even if it should it will not stay but will quickly fall. Poorly fed cows on occasion will give a milk which is so lacking in cream that it will not pass the test under mention. It cannot, therefore, always be said that the milk has been fraudulently watered, although in any case where the result of the experiment shows a poor article it would be well to change one's milkman.



It is idle to deny that there is a great deal of "butter" sold which if it is not margarine, is an indifferent substitute of doubtful composition. Of course, pure margarine, made as it is from vegetable oils, is at any time better than poor quality butter, although there is of course nothing like the genuine article, on nutritive grounds. Happily it is not a difficult matter to distinguish between margarine and all other butter substitutes, and the pure article. The so-called "spoon" test has been commonly employed by analytical chemists for a long while, and is very reliable. A sample of butter two or three times the size of a pea is placed in a large spoon and heated over an alcohol burner, or if this is not available an ordinary lamp or gas burner will do as well. Good fresh butter will boil very quietly, producing a number of small foamy bubbles. On the other hand, margarine and most examples of made-up butter will crackle and splutter, making a noise very similar to that which is caused by the placing of a green stick on a hot fire. Still another point of distinction is to be noted if a portion of the sample be placed in a bottle and this is placed in water warm enough to melt the butter. If this is kept warm for half an hour the fat will either be cloudy or entirely clear. In the former case the material is certainly margarine or at any rate not pure butter; in the latter instance however, the article may be adjudged to be of a high standard of purity and freshness. Some of the cleverly made process-butters which are on the market do not always give very definite results but a little study of the matter will enable the experimenter to judge the extent of the adulteration of which he is the victim.

Of the commonly used breakfast beverages there is little doubt that coffee is the most widely adulterated. Fortunately, again, there are some simple tests by means of which anyone may determine the character of the article which he buys. When the admixture of foreign matter is carelessly done an examination of the grains with a powerful magnifying glass will be sufficient. Absolutely pure coffee should give an entirely uniform appearance, but the presence of adulterants which may take the form of ground peas, beans or a host of other articles is readily observed. Chicory, which of course may have been openly employed is recognized by its dark and gummy grain, this is very

SIMPLE TESTS FOR FOOD PURITY.

Suggestions for the Workshop

Ingenious Expedients of Resourceful Mechanics

Depth Gage for Saws

IT is frequently necessary to make a saw cut of uniform depth, and unless a special device is provided for the purpose the task is an extremely difficult one The accompanying illustration shows a small gage which may be applied to any saw and may be adjusted thereon to prevent the saw from cutting deeper than desired. Two thin strips of wood of about the

Depth gage for saws.

length of the saw blade are fastened to a pair of arms secured to a block at the upper end A thumb screw below this block may be tightened to clamp the two strips against the blade of the saw These strips may be secured at any desired point on the blade, and thus provide an easily adjustable depth gage

A Simple Holder for Files

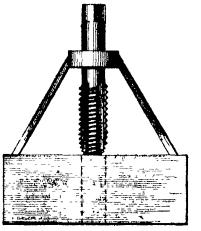
THE principal difficulty of filing a smooth surface lies in the tendency to rock the file because the handle is located at the end This tendency can be overcome to a large extent by fitting the file with a handle such as here illustrated The handle may be made of a round iron rod, a quarter of an inch in diameter, with the ends heated and flattened, as shown In one of the flattened ends two small holes should be drilled to receive the screws with which the device is secured to a block of oak three-fourths

Holder for flat filing.

inch square and 2½ inches long A hole should be drilled through the center of the wood to receive the shank of the file, and a thumb screw may be used as a set screw, to retain the file in the block The rod may now be bent, as illustrated, to form a convenient handle, with the free flattened end bearing against the file surface

With an arrangement of this sort the pressure of the hand is better equalized and it will be found easier to file a perfectly smooth surface

Scaffold Dogs



IT is always more difficult to make a scaffold with round timbers than with square timbers, for the reason that there is no solid bearing offered in the former case In order to make the scaffold secure special treatment is required. A simple device for holding two round timbers together is pictured herewith. It consists of a U-shaped piece of round iron, with its free ends bent upward. This U-shaped piece is fitted round the upright timber, while the horizontal timber is supported in the cradle formed by the two ends Before applying the hook, a dog is threaded upon it This dog is provided with a tooth at each end, adapted to dig into the vertical timber and hold the hook at the desired position The greater the weight on the hook the more firmly will the teeth of the dog be embedded into the wood At the same time, the hook may readily be removed when it is desired to take down the scaffold.

Scaffold dogs for round timbers.

A Tapping Guide

THE engraving herewith shows a handy little device for tapping holes straight The hole in the device is made large enough to take a half-inch tap and a bushing may be made to suit the bodies of taps from half inch to one-quarter As soon as the point

Guide for straight tapping.

of the tap has entered the hole the operator can see if the tap is being held square with the work. After the tap has entered the hole far enough to guide itself the guide is removed so that the hole can be tapped out deeper.

Ball-turning Device

By H. D. Chapman

THE ball-turning device illustrated in the accompanying drawings was designed to meet a special order for a large number of ball connections A number of methods of doing the work were tried, but in every case the balls were not perfectly spherical and it was necessary to lap them in their seats The final solution of the difficulty was that shown in the drawings The ball connection *A* (Fig 1) was caught in the lathe chuck. The compound rest of the lathe was removed and a worm wheel substituted This had a

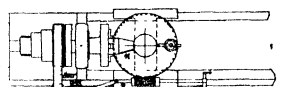


Fig. 1.—Plan view of the ball-turning attachment.

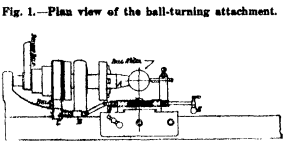

Fig. 2.—Side view showing the tool mounted on the worm wheel.

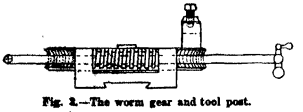

Fig. 3.—The worm gear and tool post.

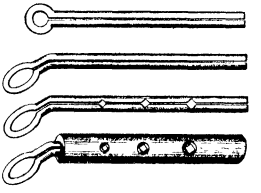


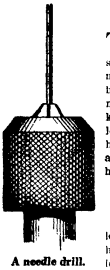
pin in the center, which was fitted to the counterbore of the cross slide. The worm wheel was also supported by means of poles which fitted in a circular T-slot, though not so tightly as to prevent the wheel from revolving upon the center pivot A tool post was mounted on the worm wheel, and in this the tool was carried.

The worm wheel which carried the tool was turned by a worm mounted on a shaft *D*, which was rotated by means of a belt *C* driven from the cone pulley of the lathe The shaft *D* was connected to the pulley shaft by means of universal joints as shown clearly in Figs 1 and 2 After a cut was taken the tool was advanced to a new position by a turn of the handle *E*. The balls turned in this manner were found to be perfectly true

Screw-driver Wrench and Tap Wrench

By G. H. Ander

THE writer is frequently called upon to repair the "reversers" of electric locomotives, and in order to do so it is necessary to remove screws which are so located as to be inaccessible to an ordinary screw driver The screws are locked by denting the edges with a center punch so that they will not readily become unscrewed Furthermore, they are so arranged that there is no way of securing a grip upon them with a small monkey wrench or a Stillson Under these conditions the writer found it necessary to make a special tool from a cotter pin about five or six inches long The eye of the pin was flattened out,



Screw-driver wrench and tap wrench.

so as to receive the blade of a screw driver and the pin was bent to the shape shown in the illustration In order to make the tool of further service, several notches were cut in the adjacent edges of the pin, so as to fit taps of different sizes These notches were made with a file, while the pin was split open for the purpose A quarter inch iron pipe was then fitted over the pin and holes were drilled in the pipe mating the notches in the pin The result was a combination screw driver wrench and tap or reamer wrench The drawing illustrates successive stages in the evolution of the tool

A Needle Drill

By Philip Edelman

THE accompanying figure illustrates a simple way to make small drills Insert a common needle in a small chuck, and file or break off the point. These home-made drills are excellent for all kinds of wood, and will cut thin lead and unglazed porcelain The handy man will welcome them as an aid in starting small screws in hard wood and for many other uses

A needle drill.

Workshop Notes

Solder for Soft Metal.—The following method will be found very handy for soldering soft metal at low temperature Add three drops of mercury to each one-half ounce of solder The solder will then fuse at a low temperature.—H D C

Drilling Compound.—In drilling tool steel such as dies, use a compound made of one pound common soda to four quarts of water, and one quart machine oil Let it stand for about one-half hour, and it will be ready for use.—A C

To Remove a Broken Amber Pipe Stem.—When an amber pipe stem is broken off, the amber part of the stem is very likely to stick in the bone sleeve, and if one attempts to take it out by force the bone sleeve will probably be twisted out of the neck of the pipe To overcome this difficulty, soak the broken stem and sleeve in alcohol This will soften the amber stem slightly, and it can then easily be unscrewed from the sleeve.—H. M Nichols.

An Automatic Mail Exchange System.

FEW if any of the readers of this magazine have failed to notice the crude apparatus in use at our small railway stations by which a single pouch of mail is delivered to a flying train, but it is doubtful whether many realize that this mail exchange system has been the subject of more discussion among government officials, more study upon the part of inventors and the source of greater loss and annoyance to all concerned than almost any other piece of mechanism in the public service.

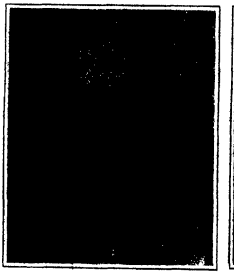
Since 1880, when the first iron catcher arm was put into commission, practically no improvement has been made in the mail exchange system in use upon our railroads.

Hardly had the mail catcher's arm of 1880 been put into commission than all connected with the service realized its inefficiency. Failure to collect or deliver the mail led to numberless petty quarrels between mail clerks and station employees. Frequently pouches thrown from passing trains or knocked from the cranes were sucked under the wheels of the cars and ground to powder. Worst of all, accidents to engine men and other employees who inadvertently put their heads out of the windows and were struck by the extending arms of the crane became so common that many inventors became interested in the subject. Plans by the hundred were suggested but few departed materially from the old design and all proved a failure when put to the test. Disappointed at their failure, the government retained the use of the former apparatus and accidents to employees and mail continued increasing rapidly as the service was extended.

To-day there are more than 12,000 stations in this country where catcher service is in operation. This service is maintained at enormous expense because of the hand labor involved.

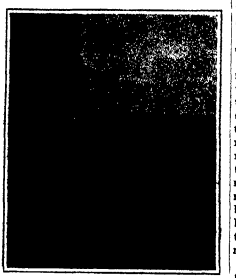
Recently a western traveling man has developed a mail exchange system that is completely automatic. Either the compartment pattern or the full sized mail car, as now used in the railroad mail service, can be equipped with the new exchange system. The car equipment consists of a receiving arm or chute attached to the sides of the car door and folded when not in actual use, so that it extends but two inches from the side of the car. Running upon rollers in a false floor between the doors of the car is a steel delivery truck, capable of handling more than one thousand pounds of mail matter and arranged to dump its contents upon a special platform at an appointed spot along the track. The platform slants away from the track to prevent the pouches from piling up as they are deposited and a low railing surrounds it to overcome the possibility of the pouches rolling under the wheels of the train.

The station equipment consists of from one to twelve steel station cranes as required and one receiving platform as just described. Located at the side of the track, 441 feet from the receiving platform, is a trip which comes into contact with its counterpart upon the mail car as the train passes. A worm gear attached to the middle of one of the axles of the mail car runs a driving shaft provided with a clutch. This clutch throws the mechanism into gear when one of the car trips attached to it comes in contact with the trip located along the side of the trackway as the car passes it. The mechanism makes one revolution and then automatically throws itself out of gear. The first quarter of the revolution rings a gong in the car to notify the mail clerk that an exchange is to be made and opens the car door, the second quarter pushes out the delivery truck until it dumps the mail and opens the receiving chute, the third quarter holds the delivery truck in position while it dumps the mail and the receiving chute in position until the station cranes are passed and the mail upon them is conducted into the car, the fourth quarter pulls the delivery truck back into the car in the position it occupied before the mechanism was tripped, folds the receiving chute into its original position and closes the door of the car. This completes the exchange and the device remains out of gear until again tripped at the next exchange station.



The operation of the mechanism being reduced to an exact mathematical basis, or ratio, where, in a movement of one degree of its revolution equals four feet of travel on the rails by the car wheels, the exchange must be positive. An adjustment is provided to take care of the different sizes of car wheels, wear, etc. Being geared to the axle, the mechanism runs fast, slow, forward or backward as the car runs, and if, for any reason, the car is stopped and backed up after passing the trip, and before the exchange is completed, the mechanism is turned backward with it. When started forward again it would bear the same relation to the car wheels as before. At terminals of the road the device can be quickly reversed and the receiving chutes changed to the opposite side of the door so that it is unnecessary to turn the mail car around for the return trip.

The station equipment is limited to 12 cranes but instead of being obliged to use pouches of a special shape and size as with the present catcher system, pouches and tie sacks, of any weight from an empty to the heaviest in the service, may be used and any class of mail handled in them. The delivery of mail is only limited by the number of mail cars in the train, as each car can deliver upon the platform the full capacity of its delivery truck, as required. All the former danger to engineer or passengers from being struck by the crane arms is eliminated in the new steel cranes which, when set for action, stand 20 inches from the side of the car. The extending arms of the crane are equipped with clamps for holding the pouches and are so protected that the pouches can be inserted into them but one way, which insures the proper operation of the system. When relieved of their burden, the crane arms automatically swing to a parallel position with the track where they remain until set for the next exchange.



For example, either part of the system may be made to work by itself so that if there is no collection to be made at a station the delivery of the mail only takes place, and *vice versa*. If no exchange whatever is to take place the mail clerk merely throws the mechanism out of gear with a lever. Human memory is sometimes tricky, however, and the mail clerk may forget to throw the mechanism out of gear before the station is reached. The gong rings and the device begins to operate. The mail clerk upon being reminded of his mistake, quickly throws the reversing lever and the mechanism runs backward and throws itself out of gear.

Accommodations have also been made for the turning of the trucks on sharp curves by the use of knuckle and slip joints, so as not to interfere with the operation of the device, and the parts beneath the floor of the car are protected from injury by water, ice and snow or from flying stones and gravel of the roadbed.

This mail exchange system has been tested hundreds of times at Overland Park, Kan., a suburb of Kansas City, in the past year. Exchanges averaging 450 pounds of mail on each trip have taken place at speeds varying from 5 to 40 miles an hour. Not one failure of the device has occurred nor a single damage to pouches or equipment thus far, and as a result of exhibitions of its operation, made in the presence of government officials, permission has been granted by the Post Office Department to use the automatic exchange for handling mail to test its practicability in the regular service. It now remains for each individual road to relieve itself of the expense, delay and danger to its employees which are inherent qualities of the present mail exchange system.

George Washington on Rumsey's Steamboat

ONE of the earliest contests involving priority of an invention was the contest of James Rumsey to the claim of John Fitch to the steamboat invention and Mr. Rumsey had no less a witness in his behalf than George Washington, who, in an indorsement forming a part of the records of the case, says

"I have seen the model of Mr Rumsey's boat, constructed to work against stream, examined the powers upon which it acts, been eye-witness to an actual experiment in running water of some rapidity, and give it as my opinion (although I had little faith before) that he has discovered the art of working boats by mechanism and small manual assistance against rapid currents; that this discovery is of vast importance, may be of greatest usefulness in our inland navigation; and if it succeeds, of which I have no doubt, that the value of it is greatly enhanced by the simplicity of the works, which, when seen and explained, may be executed by the most common mechanic.

"Given under my hand at the town of Bath, County of Berkeley, in the state of Virginia, this 7th of September, 1784.

"GEORGE WASHINGTON."

Inquiry No. 9487.—Wanted to buy a machine for ...

Inquiry No. 9488.—Wanted addresses of parties with ...

the French Government. In describing the invention in a report published by the Bureau of Manufactures, Consul-General Griffiths of London, says:

"Two cylinders are used, one of which is small and charged with 'ignifuge' gases which by connecting tubes are used to expel the solution from a much larger cylinder through an ordinary nozzle. The compound is described as follows:

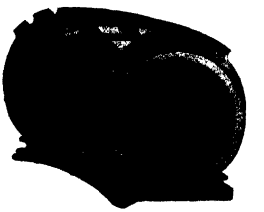
"1. A mixture of ignifuge gases, which, as a physical agent, utilizes its elastic force to project a liquid impregnated with salts and as a chemical agent renders the gases of the atmosphere which burn in every fire incombustible.

"2. An effervescent liquid, in which are found salts in a state of solution. These salts, unknown before, were obtained by the Abbe D. Daney through electric furnaces of 3,000 to 5,000 amperes. When projected they produce other extinguishing gases which increase the effect of the ignifuge gases referred to above. When reaching the blazing material they cover it with a peculiar dustlike coat, which makes it fireproof."

Notes for Inventors

False Prophets.—In the face of the enormous increase in the issue of patents from year to year, it is recalled that forty years or more ago an examiner in the division of agricultural implements of the Patent Office announced dogmatically that plows had been perfected and that no more patents would be granted for plows. About the same time an attorney engaged in soliciting patents declared his intention of going out of the business since about everything had been patented that could be.

A Laminated Rail-joint.—In a patent (No. 1,005,146) John A. Bodkin of New York city shows a splice bar forming the fish plate of a rail-joint and composed of a series of long, thin plates lying side by side and increasing gradually in width throughout the series so that their edges may coincide with one another and also with the outer edges of the base and ball of the rail.



Another Safety Device for Aeronauts.—A safety device, patented (No. 1,005,569) by Auld Weinberg De Meir of Providence, R. I., takes the form of a garment whose body portion is provided with exterior air chambers. The air chambers are arranged in superposed rows extending around the garment and open at the bottom and have a vent at the top and are adapted to perform the function of a parachute.

A Reversible Glove.—A reversible glove, which has oppositely disposed inserts, one of which forms the back of one finger and the other the front of another finger, is shown in patent (No. 1,005,437) granted to Charles H. Leavengood of Coshocton, Ohio, assignor of one-half to John A. Hesket of the same place.

A Dressing for Felt Hats.—Large fortunes have been made out of dressings and polishes for men's shoes. The men who wear shoes also wear hats, and these are oftener discarded because they lose their color than because of wear. Will not some one invent a dressing, it may be in the form of a dye, easily applied to a hat, and serving to freshen it up and improve its appearance? Possibly the dressing would have to be applied in some original way, but this can, doubtless, be devised by one experienced in the manipulation of felts, and it should be of such a character as to be easily and effectually handled by the ordinary wearer.

A Safety Apparatus for Mines.—The mine safety apparatus, provided in patent No. 1,005,196, to Maturen Gold of Hayward, Okla., and William A. Montgomery of Leland, N. M., provides a system of pipes in a mine and provided at intervals with taps, a blower for forcing air through the pipes and a helmet with an air vent and with air inlet pipes with couplings which may be connected with the taps of the main pipes. The apparatus also includes a water pipe provided with means for distributing water at different points within the mine.

The Goodyear Ideal of a Winter Tire

No-Rim-Cut 10% Oversize — With a Tough, Deep-Cut, Double-Thick, Non-Skid Tread

The Most Popular Tire

Goodyear No-Rim-Cut tires have suddenly come into dominant place in America

The sale has thrice doubled in the past two years Our last month's record shows a gain over last year of 343 per cent.

No-Rim-Cut tires are now outselling any other type of tire Over 700,000 have been used to date. And for next year's demand we have increased our capacity to 3,800 per day

Saving Half

The reasons are these:

These patented tires make rim-cutting impossible Not an instance of rim-cutting has ever occurred in the 700,000 sold

With the old type tire—the clincher tire—statistics show that 23 per cent of all ruined tires are rim-cut

This worry and expense is ended forever with users of Goodyear No-Rim-Cut tires

Then No-Rim-Cut tires are 10% over the rated size That means 10% more air—10% greater carrying capacity And that, with the average car, adds 25% to the tire mileage

This extra size takes care of the extras added to a car It avoids the blowouts due to overloading

These two features together —No-Rim-Cut and oversize— under average conditions cut tire bills in two That has been proved tens of thousands of times Yet No-Rim-Cut tires now cost no more than other standard tires

That is why this tire—our patented type—has become the leading tire of America.

The Thousand-Grip Tread

Now these tires, if you wish, come fitted with an ideal Non-Skid tread.

Not flimsy projections cut in the regular tread. Not metal and rubber, which never combine.

This is an extra tread, made of very tough rubber, vulcanized onto our regular tread Thus it gives you a double-thick tread.

The extra tread is immensely wear-resisting It is so thick that the blocks can be cut very deep. It is almost proof against puncture.

The deep-cut blocks grasp the road surface with countless edges and angles

Each block widens out at the base, so that the strain is distributed just as widely as it is with a smooth-tread tire

There has never been invented a device against skidding which compares with this Non-Skid tread

Note its thickness Note its edges and angles Judge for yourself its irresistible grip In wet and wintry weather safety requires this tire

GOODYEAR

RECENTLY PATENTED INVENTIONS.

Interesting items are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Of General Interest.

PARASOL AND UMBRELLA COVER—J. W Lewis, 124 Lower Terrace, San Francisco, Cal The object here is to provide an umbrella, parasol or like article with interchangeable covers, so that with a single frame a number of covers with different color or material may be used, and so that the life of the umbrella may be prolonged indefinitely by replacing the covers when worn

ASH HOLDER FOR CIGARS —Charles F Hodgin, 524 Chemical Block, Spokane, Wash The object of the invention is to provide what may be termed a clip-cap safety cigar smoker, and the intention is to provide a cap adapted to fit and be self retaining on the burning end

ASH HOLDER FOR CIGARS

of a cigar and to retain the ashes and prevent the same from falling while the cigar is being smoked or held in the hand The safety cap is foraminous to afford passage of air and is preferably made with a screen body of fine mesh wire or other material in the form of a cone and the inner or butt end of the cap is adapted to grip inwardly upon a cigar. A perspective view of the invention is shown in the engraving

Electrical Devices.

ELECTRIC ELEVATOR BRAKE —Volney W Mason, Providence, R I The larger illustration shows the application of the brake to the right and left driving shaft of the electric motor on which are two worms, which mesh into two worm gears on the hoisting drum shafts On the extreme left is the square frame supporting the rheostat for varying the strength of the electric starter The driving shaft is coupled directly to the motor shaft by a flanged coupling which also forms a brake pulley The brake arms are suspended at their upper ends from a stud supported upon an inverted V-shaped frame rigidly attached to the base block The brake arms extend downward below the brake pulley in a straight line, in which are longitudinal slots The transverse horizontal operating brake lever is pivoted to a stud stand in the space between end portions of the brake arms as shown in the small illustration, and carries friction rollers on the two stud bolts shown on each side of the central stand, which are free to move vertically within the slots. The left end of the lever is attached to the lower end of a solenoid operating vertically within an electro-magnet, the latter being shown with its connecting wires to the right of the hoisting drum in the large illustration In the diagram view the operating lever is shown drawn up by the solenoid of the electro mag net in this position while the current is on, which holds the brake arms as well as their brake surfaces apart away from the brake pulley. When the operator in the elevator breaks the circuit by the usual switch the solenoid drops also the operating lever by its weight and an adjustable weight attached thereto, bringing the lever into an inclined position (shown by the dotted line) which causes the brake arms to clamp the brake pulley and stop movement of the motor shaft as well as that of the elevator The general construction of the frame (in the large engraving) embodies means of adjustment not usually found in machinery of this class all the parts being very accessible and convenient in erection or removal in case of repairs

Hardware and Tools.

PLATE LIFTER —Joseph E Wenman, New Philadelphia Ohio The accompanying picture represents the plate lifter in a perspective view The invention relates to a form of lifter or detachable handle for articles, especially those which are too hot to be readily handled without the interposition of some such tool The object is to provide a utensil having

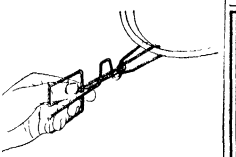

PLATE LIFTER.

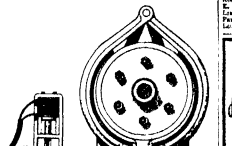

parts, which may readily be constructed from metal wire without the use of any connecting pivots The relative parts are so constructed that they may be readily and removably locked in position In the construction each member is made continuous of one length of wire, and there are no drilled joints.

FISH GRIP—J Buttman, 180 Hamburg Avenue, Brooklyn, New York In this patent the object of the inventor is to provide a fish grip for the use of fishermen fish dealers and other persons, and arranged to permit of obtaining a firm hold on a live fish when taking it off the fish hook, or out of a net or for holding a fish for scaling, cleaning or other purposes

Machines and Mechanical Devices.

RULE CUTTING MACHINE J A Brenaris, Albion, Mich This machine is adapted for cutting bent rules as well as straight ones When a bent rule is to be cut, the shelf or gag bar, which serves as a support for straight rules while being cut is raised and swung back out of the way, which allows due access to the cutting mechanism so that the bent rule may be manipulated in the required manner

NOTE. Copies of any of these patents will be furnished in the SCIENTIFIC AMERICAN for ten cents each Please state the name of the patentee, title of the invention, and date of this paper

ELECTRIC ELEVATOR BRAKE.

Use KEROSENE Engine FREE

Amazing "DETROIT" Kerosene Engine shipped on 10-days' FREE trial to prove kerosene cheapest, safest, most economical fuel. 12 models, 2 to 60 H.P. Lowest price ever given on reliable farm engine. If best, pay nothing.

Gasoline Going Up!

Automobile owners are burning up so much gasoline that the world's supply is running short. Gasoline to be 30 to 40 higher than coal oil. Still going up. Save price of coal oil by using "DETROIT" three plans gasoline. No waste, no evaporation, no explosion from coal oil.

Amazing "DETROIT"

The "DETROIT" is the only engine [illegible] coal oil successfully; uses alcohol, gasoline, [illegible] Starts without cranking. Runs [illegible] perfect—no carburetor adjustments—runs [illegible] is simplicity, power and strength. Rotated on [illegible] 500 R.P.M., is built ready to ship. Complete and [illegible] before crating. Comes all ready to run. Power [illegible] starter, sprocket pulley, grinder, [illegible] and [illegible] electric-lighting plant. Prices (stripped) [illegible] Built any place on 10 days' Free Trial. Don't [illegible] till you investigate amazing, money-saving [illegible] "DETROIT." Thousands in use. Some near you. [illegible] on. If you are first in your neighborhood to write, [illegible] you Special Extra-Low Introductory prices.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc This will greatly facilitate answering your questions, as in many cases they have to be referred to experts The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12561) W S B writes: In re "Musical Sands"—SUPPLEMENT, September 30th, p. 224—a good specimen exists at Manchester, Mass., where the sand of the beach near the hotel creaks audibly when walked on A Very true; and there used to be a sounding beach between Rockport and Gloucester, Mass., when we used to summer on that coast The waves raised the pebbles and smaller stones, and as they fell back they gave a musical tone by their rapid blows against each other

(12562) A. F. K asks. 1 How much by weight and what number and kind (single or double covered) of platinum wire will be necessary for one induction coil such as is used for pump spark ignition on gasoline engines? A For the primary of an induction coil giving an inch spark use about 50 feet of No 14, B & S single cotton-covered magnet wire Double-covered wire may be used with some advantage in insulation, but a loss from the increased space taken up by the wire 2 How much and what number and kind of secondary wire is necessary for the same coil? A The secondary may contain 1¼ pounds of No 36 wire Silk-covered wire makes the smaller coil, but cotton-covered wire is stronger mechanically 3. Is a condenser generally used with such coils? A A condenser is necessary You will find all details for making coils, machinery for winding, etc., described and figured in our Collins's "Making of Induction Coils," price $1. Nearly every one making a coil should have at hand

(12563) C M asks In one of your older issues I saw how to make a luminous lamp I tried it, but it will not work I heated pure olive oil for fifteen minutes in a small glass bottle, put in a piece of phosphorus and corked it up, but it gives off no light at all The phosphorus shake to the bottom of the glass Can you tell me what is wrong? A If you will take the cork out of the luminous bottle and shake the contents in the dark, so as to have some air from the outside enter the bottle, you will see the phosphorus that the oil has dissolved any of the phosphorus The oil will not shine unless some oxygen from the air can get at the phosphorus We have had one of these for years which still shines whenever we shake it up and bring fresh air into contact with the phosphorus

(12564) J. T P asks Can you tell if directions for making a pinhole camera have ever appeared in your publication? If so, to what number, and at what price can I get this copy? I wish to make an 8 x 10 camera Have a book already, telling how to make an apparatus to take 4 x 5 plates This says make pinhole with No 10 needle Now tell me this At what distance from pinhole should an 8 x 10 plate be, and what size needle should I make the pinhole with? Also, what is the length of exposure for clear sky, hazy sky? A In the pinhole camera the size of the plate is not directly connected with the size of the hole at all. The distance of the plate from the hole for best definition is determined by the size of the hole. We give you a table from a French writer on this subject

Aperture.	Distance of Plate
0 012 inch	4.33 inches
0 016 inch	7.87 inches
0 02 inch	11.8 inches
0 024 inch	17.32 inches

The pinhole should be perfectly round, and carefully bevoled on both sides, as perfect as it can be made, if you would get best effect It will include about 170 degrees If then you secure a wide view at a distance of 8 inches with the aperture 0 016 inch, and wish a view giving a detail of some part of this wider view, you have only to move the plate back to 17 32 inches and use the 0 024 pinhole The same width of view is taken in by the pinhole in both cases, but at the longer distance only a small portion of the view will fall on the same sized plate. The result is an enlarged view of a portion of the former picture A wide range of the time of exposure is possible with skill in managing the development With the smallest pinhole given, the exposure will be at least twenty-five times longer than with a lens giving the same size of picture, and with the longer distances the exposure must be greatly increased in length, probably two hundred times for the 17.32-inch distance You will have to work these matters out for yourself by experiment. The light is very faint when spread over a large plate, when the aperture is only 1/40 inch at the largest.

1911 Atlas Of the World Given FREE

With New Census

To the readers of THE SCIENTIFIC AMERICAN who take advantage of this **Offer** now made in connection with

Webster's NEW International

Not A New Edition A Mere Revision But a New Creation

400,000 Words and Phrases
6,000 Illustrations
3,000 Pages
New Gazetteer of the World
New Biographical Dictionary

Readers of THE SCIENTIFIC AMERICAN can now secure this **Newest** and **Most Complete Reference Library** in Dictionary Form on the following remarkably easy terms: The entire work in full leather (with Atlas)

Delivered for $1.00

In Rich, Full Red Leather Binding

and easy payment thereafter of only a few cents a week in the United States or Canada

WHAT EMINENT AUTHORITIES SAY

United States Court of Claims: We consider the work a distinct advance over other dictionaries which have come under our observation

Nicholas Murray Butler, President Columbia University: It marks new advances even upon its excellent predecessor"

Dr. C. H. Parkhurst, New York City: "It is a marvel of completeness and an indispensable feature of the library of every man who either reads or writes."

New York Sun: "Not a word or a definition in which some change for improvement has not been made"

"To have this work in the home is like sending the whole family to college"

To those who respond at once we will send a copy of an amusing "Test in Pronunciation" (with key), entitled "The Americanization of Carver," and also a "Red Face" simile Booklet of interesting questions, with references to their answers

The ATLAS

In the new Census 1911 **New Reference Atlas of the World** containing 128 pages of maps beautifully printed in colors with marginal reference indexes, besides illustrated descriptions of **PANAMA CANAL**; all handsomely bound in red cloth size 10¾ x 14¾. Mail this coupon at once to

The Scientific American Cyclopedia of Formulas

Edited by ALBERT A. HOPKINS

SIZE 6½x8¾ INCHES 1077 PAGES 200 ILLUSTRATIONS
CLOTH, $5 00 HALF MOROCCO, $6 50 POSTPAID

¶ This valuable work, which is partly based on the twenty-eighth edition of "The Scientific American Cyclopedia of Receipts, Notes and Queries," contains a collection of about 15,000 selected formulas, covering nearly every branch of the useful arts and industries Never before has such a large collection of valuable formulas, useful to everyone, been offered to the public

¶ This work may be regarded as the product of the studies and practical experience of the ablest chemists and workers in all parts of the world, the information given being of the highest value, condensed in concise form convenient for ready use. Almost every inquiry that can be thought of relating to formulas used in the various manufacturing industries, will here be found answered

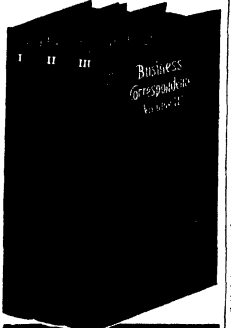
¶ The formulas are classified and arranged into chapters of related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired

¶ Those engaged in any branch of industry will probably find in this volume much that is of practical use in their respective callings. Those in search of salable articles, which can be manufactured on a small scale, will find hundreds of most excellent suggestions It should find a place in every laboratory, factory and home

An eight page descriptive circular and table of its contents will be furnished on application

MUNN & CO., Inc., Publishers, 361 Broadway, New York

It's the Wonderful Columbia Kerosene Engine at our Risk



Test it out in your own place for fifteen days. Give it the hardest engine test you can think of. Compare it with any other engine. If the Columbia doesn't develop more power at less cost, send it back quick. No conditions. We are willing to let you be the judge and jury. Kerosene (common lamp oil) is by far the cheapest fuel today. The price of gasoline is climbing all the time. Fuel becomes records the same, and in the right engine it lasts longer and produces more power per gallon than gasoline. You get All the power when you use a Columbia, because it is the right engine. It is the one really simple and perfect kerosene engine. It never leaks when you need it most. It is always on the job.

Write for Particulars of Our Big Special Offer

We are going to double our output for next year. We can do it easily. It is just a matter of getting enough users to test the Columbia for themselves. So we are making a great special money saving offer on Columbia Kerosene Engines. This offer is liable to be withdrawn at any time, so write today for full particulars, for it is a money saver you would hate to miss. Free Book No. 29 tells of engine facts you need to know, and free.

A Library of the World's Greatest Business Letters

The letters that have sold the *most* goods, collected the *most* money, settled the *hardest* complaints, won the *best* jobs, built the *strongest* business—analyzed and dissected for you to learn from, to adapt to your needs, or to develop an original style of your own—with the best examples actually reproduced as they were used and graphically explained point by point.

Here in these three volumes, 1672 pages—are packed the success-secrets back of the letters that are actually winning the biggest results today, that are bringing orders from you and me, and making other men's fortunes.

Every striking idea found in use by mail order house, wholesaler, manufacturer, retailer, real estate or insurance man, bank, collector, individual salesman or complaint clerk was followed out and its returns studied. This mass of information—the cream of the gold mine of absolute facts was then *charted* and *diagrammed*—and developed into one complete, yet concise library so clear and simple that from it any busy man can pick out for any sort of proposition, an idea or suggestion that he can *know* in advance to be successful, or can turn to for original inspiration.

Special Forced Edition—$1 DOWN

$1 with this coupon brings to you transportation prepaid, the complete 5-volume Business Correspondence Library, 1672 pages, 8½ x 11 inches, handsomely bound in T-Pattern Vellum, filled in panel, with titles in gold. $2 per month for 4 months thereafter—less than 7 cents a day—pays for them complete. Also a subscription to your SYSTEM, the Magazine of Business, every month for the 5 full years—12 numbers of this remarkable business magazine, filled with plans and ideas.

SYSTEM stands pre-eminent the Monthly Magazine of Business—$60 to $90 a year to subscribe for it. You cannot afford to miss a single one of the 12 numbers that come to you during the next 5 years. Each one is going to win trade, stimulate success, bring down expenses, enlarge profits. With this coupon you receive SYSTEM every month for two years and more at once the complete new 5-volume Business Correspondence Library. Send only $1 with the coupon.

Here at last is the clear, complete, specific method by which the business man, the sales worker, the man in any line of selling, can put more business within reach—can make his letters achieve and bring at his selling talk—the young man develop himself into a power with his employers—by which banker, real estate agent, insurance man, credit man can do his business better with people, certainly the style and character that commands. Do not risk losing your chance at the advance within—act today.

Other methods

"I located within two minutes after I opened the first volume, two paragraphs that gave the ideas I can use in my business, worth many times the price."—R. B. Davis, Saint Agnes, Kansas City, Mo.

"I consider that every business office should have them for the benefit of their employees."—F. J. Westervelt, Supt., 27 E. 28th Street, New York

I enclose $1. Send me at once, transportation charges fully prepaid, the 5-volume Business Correspondence Library—1672 pages—bound in T-Pattern vellum and enter my name for a full 5 years subscription to SYSTEM, the Magazine of Business—to begin with current number. I promise to remit $2 each month for the 4 following months, making $9 in all. Sci. Am. 11-11

A "Mars" Visitor

To the Editor of SCIENTIFIC AMERICAN:

I shall be infinitely obliged and highly thankful to you if you will kindly take on yourself the trouble to inform me at an early date as to the truth and accuracy of the following incident said to have occurred in Mexico, which has excited the amazement of the people in this quarter of the globe, especially in the absence of any mention of it in your world-renowned paper, the SCIENTIFIC AMERICAN, which I have been an interested reader of; nor do I find any such reliable authority to be referred to on the topic

The local papers here describe the descent of a man from Mars accompanied with a clap of thunder and lightning which put all the people of the locality to flight with the single exception of a scientist, who alone had the courage to proceed to the scene of the occurrence to satisfy his curiosity, and he is said to have described the man to be twenty cubits long, his speech being above the book of the scientist At last, the man, as is said, after a short stay, flew away Here I request you to throw some light on the subject which will bring us from the realm of uncertainty to that of truth

Your paper has proved very valuable to me Almost all its articles are intrinsically interesting, opening to me a broad field of scientific knowledge It reveals to me a museum of rare objects of curiosity and wonder. I should also thank you warmly if you would inform me through your columns how far the progress of the astronomers has, in counting stars, till now gone

I have much to talk about and many things to converse upon, but the long distance stands in the way, as the postage (which comes to the engineering office and from which source I see it) takes a month to reach the office

ABRAR BAKSHI

Cuttack, Bengal, India

[The key to this extraordinary letter from our far-away correspondent will probably occur to those of our readers who may have chanced to be in the locality when "Bud" Mars, the aviator, made his recent flight into Mexico. With this incident in mind, and allowing for the errors of hearsay and translation of Mexican vernacular into Hindoo, we can see how "the local" papers came to "describe the descent of a man (from the) Mars," etc. To the Mexican countryman who probably never even have heard of, much less seen, an aeroplane, the descent out of the heavens of this apparition (with its engine back-firing and shooting out flame and thunder claps) may well have suggested the supernatural. In some such fashion, doubtless, were founded and perpetrated many of the myths of ancient Greece and Rome.—ED.]

Safety Devices in the Cab

To the Editor of SCIENTIFIC AMERICAN:

I was glad to see in your issue of October 7th the very clear and forcible statement of J B Wells in opposition to the proposed safety stop locomotive throttle Two possible solutions of the problem present themselves

What happens when a man suddenly loses consciousness from any cause? He collapses. Must we not look to this fact for our solution of the question? It is quite possible to require an engineer to perform his regular duties standing within a light, semi-circular guard His collapse in any direction would immediately throw a considerable pressure upon the upper rail of this guard, which would result in the operation of levers shutting off the engine and applying the brakes

Or perhaps a preferable mode of achieving the same desirable end is by a footplate upon which the engineer stands. His collapse would remove all, or in any event most, of the pressure from this plate This is infinitely better than having the pressure at the throttle and brake valve handle, and leaves the hands of the engineer free to perform any duties he may find necessary. Any difficulties presenting themselves may, I am convinced, be met and mastered with comparative ease.

Bridgeport, Conn. ARTHUR POWELL.

The Battleship "Orion"

(Concluded from page 481.)

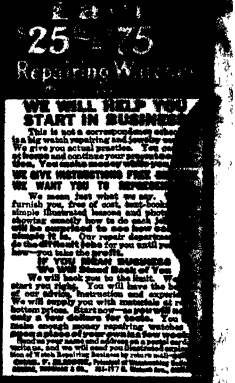
cent" (21.9) and the "Superb" (21.63); while the four completed battle-cruisers, designed for 25 knots, have all made well over 27 knots.

Principal interest in the new ship naturally centers in her armament First of all as to its disposition: and here it is to be noted that the British Admiralty has been slowly working round for some years toward the consistent American principle of the all-center-line arrangement, which is, after all, as essential to the ideal dreadnought as unity of caliber. The second turret from aft, which in previous ships is on the same level as the aftermost, was raised so that the aftermost turret could be brought up under its guns. There is a general impression that the object of this arrangement was to increase the astern fire, but that is not so. The primary object was to save length; and although the special trials which the "Neptune" carried out in the Mediterranean showed that the superposed guns could be fired directly astern if needed, they also showed that such a maneuver was not at all advisable. In the case of the "Orion," no attempt has yet been made to fire more than two guns (those of the first and fifth turrets) forward or aft, nor is it likely to be.

So far as the arrangement of the turrets is concerned, the new ship has no exact counterpart in any fleet. She most nearly resembles the "Delaware" class, with, however, the following difference: In each case there are two turrets forward and three aft of the superstructure; but instead of the third turret from aft being raised to have further astern as in the "Delaware" class, the "Orion" has the second (or middle) turret so raised. In other words, the forward turret arrangement is repeated astern, and a fifth turret is placed just abaft of the superstructure, on the same level as the aftermost.

Each turret contains two 13.5-inch guns, of whose ballistics little is known outside the gunnery circles of the fleet itself The weight of the gun, usually placed at 80 tons, is 76 tons, and its length is 45 calibers, while the weight of the projectile is 1,250 pounds. The muzzle energy, firing with full charges, is believed to be 60,000 or 70,000 foot-tons (as compared with 53,400 foot-tons for the latest 12-inch model in the British service); and the perforations of 26 inches of Krupp cemented steel at 3,000 and of 22 inches at 5,000 yards (with capped armor-piercing shot in each case) are believed to be reliable but must be accepted with reserve For purposes of comparison it may be stated that the 13.5-inch guns mounted in the obsolete battleships of the "Royal Sovereign" class (now being sold out of the service) are 30 calibers in length, weigh 67 tons, and fire a 1,250-pound shell with a muzzle energy of 38,230 foot-tons, or just about half the power of the new weapon. The penetration of the old gun (Krupp steel) at 3,000 yards is 11 inches

The following table shows the increase in the size and power of successive types of British all-big-gun ships:



Completed.	Type Ship.	Length Feet.	Tons.	Broadside. Pounds.
1906	"Dreadnought"	490	17,900	6,800
1909	"Bellerophon"	490	18,800	6,800
1910	"St. Vincent"	500	19,250	6,800
1911	"Hercules"	510	20,000	8,500
1911	"Orion"	545	22,500	12,500

The anti-torpedo armament of the "Orion" consists of twenty 4-inch 31-pounder rapid-fire guns, mounted in two groups, each of ten guns, disposed as shown in the illustrations. In the firing of the heavy guns several of the mountings of the smaller weapons were started, and so seriously that it is understood some new arrangement for them will be found.

The following sister ships to the "Orion" are approaching completion:

"Thunderer," "Conqueror," "Monarch," to be completed by March 31st, 1912. "King George V.," "Centurion," "Ajax," "Audacious," to be completed by January 16th, 1913.

The last four will be slightly larger—about 24,000 tons—due to better protec-

Simple Tests for Food Purity

(Concluded from page 428.)

...rmful if it is present in large quanti... Further, nearly all the adulterants ...powered present a shiny appearance. ...arnish coffee always looks somewhat ...ill. A more rapid way of testing any ...kind of ground coffee is that pictured in ...n accompanying illustration. Take a ...tumbler of water nearly full to the brim, and scatter about half a teaspoonful of the grains upon the surface of the liquid. Pure coffee contains a large amount of oil and on this account the grains will float with a very few exceptions. Practically all the adulterants in use will sink to the bottom of the tumbler. The presence of chicory in the sample is at once known by the almost instant coloring of the water a deep brown shade. If the tinting is very intense chicory has been added to a positively unwholesome extent. Pure coffee grains will not color cold water, at any rate not until the passing of a considerable interval. In these experiments it is interesting to include a few samples of the so-called coffee substitutes, many of which will be shown to contain a large amount of coffee, and this in spite of the assertions of the manufacturers.

The only means by which illicit additions to tea can be detected is by an examination of the dried leaves after one has become fully acquainted with the genuine article. Leaves of many kinds of plants have been employed in this connection, of which those of the wild plum are perhaps the most commonly used. Nowadays, however, at the place of its production tea is so cheap that it scarcely will pay the manufacturer to do much in the way of adulteration. Cocoa is rather different, however, and there is little doubt that huge quantities of this substance are sadly behind what they should be in the way of quality. Some form or other of starch is a very favorite adulterant with certain sections of the trade. This may be at once detected if about a teaspoonful of the powder is placed in a cup and boiling water is added. If any starch is present the liquid shows a very marked thickening, a happening which should not be noticeable to any extent in the genuine cocoa essence. A much more harmful adulterant is the addition of cocoa shell, unfortunately the presence of this is not very easily discovered save by the help of a microscope. If the powder has been unreasonably ground it may impart a slight grittiness to the mixture, though of course the skilful manufacturer will take great pains to avoid this.

There are perhaps no articles of food which are more commonly adulterated than jams and jellies. It is not an exaggeration to say that very little of the material sold of this nature is simply the fruit named on the label embodied with pure sugar. Most of the adulterants, such as those used for coloring and adding to the bulk of the jam, are fairly harmless, though none is of course desirable. Starch is a very common adulterant in jam though owing to the cloudy properties which it would give to a clear jelly it cannot be used with much effect in this article. In the case of jam it is impossible to detect its presence without a small test. Dissolve a teaspoonful of jam in half a teacupful of hot water. Through a piece of muslin strain away any solid matter which is left. Now add drop by drop a solution of potassium permanganate until the mixture is practically decolorized. In some cases of artificially colored jams the decolorization may not be very complete, but this can hardly affect the final stages of the test. When the liquid has quite cooled down add a single drop of tincture of iodine, and if any starch is present the solution will turn a decided blue color. Even more commonly used than starch is glucose, and to determine the presence of this adulterant a slightly different test is necessary. Again the same quantity of jam or jelly should be dissolved in warm water, in the former instance it will be necessary to strain away the insoluble matter as before. Now allow the solution to become quite cool and then add an equal amount or possibly a little more of strong alcohol. In order that the subsequent stages may be closely observed it is as well to carry out the experiment in a glass vessel. If the sample is a pure fruit one there is very little precipitation except perhaps the smallest amount of proteid bodies. On the other hand should glucose have been employed in the manufacture a cloud of dense whiteness separates from the rest of the solution, and finally settles down at the bottom of the tumbler. This may be taken as conclusive evidence that glucose has been used as an adulterant.

In order to render the appearance of the pickles more attractive copper, to a greater or less extent, is frequently employed in the preparation of pickles. This may not have been directly added in every case, for the practice of boiling the pickles in copper jars is quite sufficient to account for its presence. Scalding vinegar has a powerful effect upon copper a fact that should be noted by every cook. Even when only present to a small extent this mineral is highly injurious as of course it is a rank poison. Pickles of a very bright green color should always be suspected and put through the following test. Mash some of the material with a fork until it is well crushed, and then place the material in a stoppered bottle. Add to this a solution composed of ammonia and water in equal parts and shake the whole well. If there should be the smallest trace of copper the ammonia turns a blue color. Copper is often used to deepen the green of imported canned goods such as peas, beans, spinach, etc. In some articles of this nature it has been found to a really alarming extent. A very interesting experiment to detect its presence is one involving the use of hydrochloric acid, a strong corrosive which of course must be used with extreme care and kept away from contact with the skin or clothes. Still the test is so curious that many people will be interested to try it. Mash a sample of the vegetables and place a teaspoonful in a teacup, add thirty drops of hydrochloric acid. Set the cup on the stove in a saucepan containing boiling water, drop a bright wire nail into the cup and keep the whole thing boiling for twenty minutes. Stir the mixture all the time with a splinter of wood. At the end of the time stated drag out the nail, when if copper has been used with the vegetables, the article will be found to be heavily plated with that metal.

A final word on the subject of canned goods may not be out of place. These are used so widely nowadays that the laws controlling their preparation are rightly stringent. Still now and again, for no very clear reason something goes wrong with a tin of goods. This is almost always shown by an alteration in the external appearance of the package. The top or the bottom appears more or less "blown out" and when this is the case even to a small extent the contents should be unhesitatingly condemned. There is always grave risk attending the consumption of articles contained in unsightly tins.

Major John Burger Waring

MAJOR JOHN BURGER WARING, brother of Col. George E. Waring, died on October 30th at the age of seventy-seven. Major Waring was well known as a pioneer steel pen maker. The two types of pens invented by him were named the Chase medallion and the Washington medallion. During the civil war he invented an improved device for spiking cannon. Enlisting as a lieutenant in the Fourth Missouri Cavalry, he attained the rank of major in the Ordnance Division. After the war he invented an apparatus for removing silk from the cocoon, also a rock drill and many other mechanical devices. All told he secured over seventy patents.

IN 1909, 65,399,889 barrels of cement were produced in the United States, valued at $52,797,973. In 1900 the production was only 17,231,150 barrels. In 1905 it was 31,675,357 barrels, in 1906 it was 51,060,445 barrels, and in 1908 it was 52,810,935 barrels.

JUST PUBLISHED *A New and Authoritative Book*

MONOPLANES and BIPLANES

THEIR DESIGN, CONSTRUCTION & OPERATION

The Application of Aerodynamic Theory, with a Complete Description and Comparison of the Notable Types

By GROVER CLEVELAND LOENING, B.Sc., A.M., C.E.

CRITICISMS

"The first treatise upon aviation which we have seen which may be styled really complete. . . . . Actual aeroplane designing is the central theme of the volume. . . . . The prominent types are exhaustively compared. . . . . The illustrations are a notable feature."
—*Rochester, N. Y., Chronicle.*

"A very complete account of the theory of heavier than air flying machines with a technical description of nearly all the present types of aeroplanes. . . . Presents in compact shape the substance of aerodynamic theory. . . . . Easily comprehensible to the reader who can concentrate his attention. . . . . It is the most scientific popular book on the aeroplane that we have come across so far."
—*New York Sun.*

"Many writers have failed to realize the demand which exists for aero literature in which mathematical deductions are a necessary but not predominant part of a comprehensive exposition of the entire subject. For a writer to steer a straight course between the mazes of trigonometry on the one hand, and the superficialities of mere discussion in a popular vein on the other is to accomplish what can be done only by one who is himself a thorough student in the finer details, but who can sufficiently divorce himself from the mathematical atmosphere as to present the whole subject from a broad standpoint, making it readily intelligible and informative to the less erudite seeker after knowledge."
—*Phila. Inquirer.*

"Students learned in aerodynamics and laymen profoundly interested in aviation will find equal delight in reading 'Monoplanes and Biplanes.' The book is a welcome addition to the libraries of those who have watched the future of aerial navigation, and doubt a work treating calmly of the heavier than air machines written by an acknowledged expert and with no hobbies hidden in the closet."
—*Boston Journal.*

"While enthusiastic in his interest as becomes one who has written an superb a volume, Mr. Loening is also rigidly accurate as the most exacting scientist could demand. Here is a work which is at once a history and textbook which may be depended upon for everything that is within the range of actual knowledge. To say that 'Monoplanes and Biplanes' is at once new and authoritative with reference to the entire subject and that it is practical in the highest degree is the just praise due to this volume."—*Buffalo News.*

"Mr. Loening has written, in fact, for the man who wishes to apply practically the experience that has already been gained."
—*New York Times.*

361 Broadway New York

The test of a magazine's merit

is that its readers tell their friends about it.

We recently asked our subscribers to send us the names of those whom they believed the Scientific American would interest, and we are gratified to find that so many of our subscribers believe that its merits will appeal to such a large number of their friends. Have you sent a list? If not,

Here is the way:

Simply send us the names and addresses of the people whom you think will be interested and we will do the rest. An accurate record of all names received in this manner will be kept, and for each new subscription we get from any list we will extend the subscription of the person who sent us the list for four months. Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year.

Of course you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own subscription will be renewed.

Be careful to write the names and addresses plainly and don't fail to put your own name and the address at which you are receiving the Scientific American on each list you send.

Address all lists to Circulation Department, Scientific American, 361 Broadway, New York.

WOOD DISTILLATION for manufacturing ALCOHOL and other products of the process

¶ Profits from refuse wood and sawdust are in reach of any one who will locate near a sawmill. The Scientific American Supplement files contain a series of valuable articles on this topic which are contained in the following numbers:

1610—A General Review of the Subject of utilizing wood wastes, and the uses to which the wastes may be put.

1684—The "steam" and "destructive" distillation processes, and memos the numerous **products obtainable** from the complete operation.

1681—Distillation of soft wood, and gives the proportions and quantities of each products obtainable, and the various processes used.

1723 and 1724—The general subject of the utilization of wood wastes, giving all the products by a clear and valuable diagram showing their relations to each other, and many illustrations of appliances.

1582—The manufacture of wood alcohol by a German process which first converts sawdust and scraps to glucose and then to alcohol, leaving the residue of the wood with 75% of its heating value, and in condition to briquette without a binder.

1789—Prof. Ruttan's article on the **manufacture of wood alcohol,** a very comprehensive discussion.

1643—Dry distillation of Beech and other hardwoods comparing European and American methods, and giving the quantities of products obtained.

1335—Charcoal manufacture in Germany, with complete recovery of by-products, their description and uses.

1472—"Distillation of Pine Products" refers especially to turpentine manufacture, but covers the by-products as well, and gives information of the profitable nature of the business.

1551—Refers to acetic acid, wood spirit and acetone from distillation of wood, and gives a good description of the necessary apparatus, and particularly of the points to be observed in operating the plant.

1736—Production of Alcohol from Cellulose, how wood and wood products may be used.

Each number of the Supplement costs 10 cents. A set of papers containing all the articles above mentioned will be mailed for $1.20. Order from your Newsdealer or from us.

34 YEARS' EXPERIENCE IN THE MANUFACTURE OF HIGHEST GRADE MECHANICAL VEHICLES

THE beauty of the Abbott-Detroit Closed Cars is the result, rather than the cause, of their useful and comfortable design. It is in this type of Gasoline Motor Car construction that the character of a manufacturer's product is most clearly revealed.

There is such a chance for imperceptible, shoddy work or such an opportunity for the display of elegance and refinement, that the little things which tend, on the one hand toward cheapness and on the other toward quality, in a maker's policy, stand out boldly

Abbott-Detroit

Closed Car Bodies are not skimpy, badly fitted, poorly finished, soon becoming squeaky and spotted.

They are of the highest grade in every particular and their mounting is such that they ride easily and do not rumble

The upholstery is thick and yielding and of such a shape as to allow the finest clothing and hats to be worn with ease and without disastrous effects

Both our Coupe and Limousine are well suited for shopping, calling, town car use and theatre going, particularly in inclement weather, when they are always comfortable and snug inside

Abbott-Detroit "44" Fore-door Limousine, fully equipped with Gray & Davis nickel plated Bullet electric headlights, electric side and tail lights, two (2) 180 ampere hour lighting batteries, Tungsten lamps,—body of lamps black enamel with nickel plated trimmings, 36x8 inch tires, front; 37x4½ inch rear, demountable rims, horn and complete set of tools, **$3000.**

Abbott-Detroit "30" Colonial Coupe, fully equipped with nickel plated Bullet electric headlights, electric side and tail lights, two (2) 100 ampere hour lighting batteries, Tungsten lamps, 34x4 inch tires, demountable rims, horn and complete set of tools, **$2150.**

Dynamo Equipment for Electric Lighting, $90 extra Abbott Self Starter, $50 extra.

These and all our other cars are completely described in our 1912 Art Catalogue

ABBOTT MOTOR COMPANY

613 WATERLOO STREET, DETROIT, MICHIGAN

There's a Place For This Profit-Earning Car In YOUR Business

If you depend on the horse-and-wagon system of delivery, let us show you in dollars and cents what International Commercial Cars have done for others. They will do the same for you.

If you own big motor trucks, let us show you how an International will save time, fuel, oil, and wear by doing all your light hauling.

International Commercial Cars

have a place in every business where prompt and efficient service is necessary. The man who uses big trucks for his heavy hauling should buy Internationals for the lighter work—making quicker trips, more prompt deliveries, and increasing the efficiency of his delivery service.

The I H C reputation for highest quality insures a car that is right—a car that is simple, strong, durable, economical, and dependable.

Whatever your delivery problem is—let us help you solve it. Get the facts before you take any definite step. You will be vitally interested in the information we want to place before you. Write us fully.

INTERNATIONAL HARVESTER COMPANY OF AMERICA
(Incorporated)
Harvester Building Chicago U S A

Public demand produced This Roadster

HUPMOBILE ROADSTER $850

F. O. B. Detroit, including complete equipment of top, windshield, gas headlights and generator, oil lamps, tools and horn. 110 inch wheelbase, two passenger body, with genuine cane seat and highly finished steel and wire wheels. Rear deck mounted on rear axle. Ample room for luggage and extra tires. Four cylinders, 30 H.P., selling grade Hupmobile.

Hupmobile

You can thank the insistence of the motor-buying public for this new Hupmobile Roadster

Newspaper reports of the impressive performances of the World-Touring Hupmobile have had a three-fold effect

They have stimulated, everywhere, the always extraordinary demand for the Hupmobile Touring Car and the Hupmobile Runabout.

And, in addition, they have given rise to a new demand, which has voiced itself in a persistent call, from all parts of the country, for a Hupmobile Roadster with the same chassis and the longer wheelbase of the globe-girdling car

The achievements of the World-Touring Car—which is winning new honors at this writing in far-off lochs—have fired the public imagination, and advocates of the roadster, everywhere, have urged our dealers to give them a Hupmobile of that type

So, here you have it—a Roadster with the specifications which have proven so marvelously efficient in the 25,000 miles of land travel credited to the Hupmobile Touring Car since it left Detroit last November, and the thousands of touring cars in use in all parts of the world

Having its two seats midway between front and rear axles, and with the flexible springs and long wheelbase of the touring car, the Roadster is a particularly easy-riding car

Thus it is especially fitted for road work

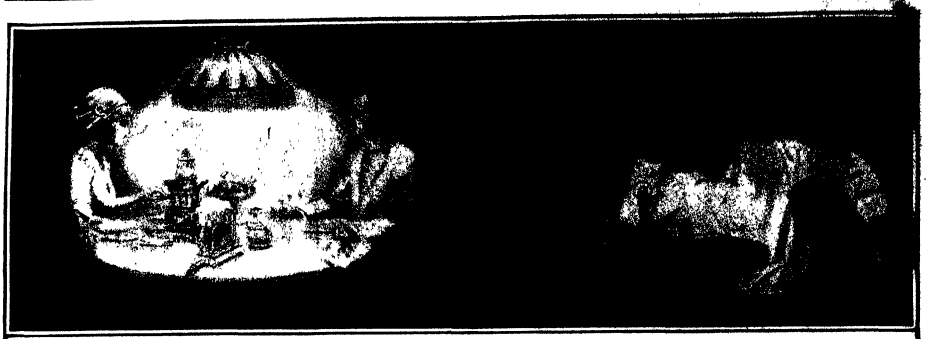
Its power plant and other mechanical features are identical with those which have given the Hupmobile its high reputation and durability, long life and efficiency—and you can see for yourself that it is one of the most beautiful members of the notable Hupmobile line.

The tool box on the rear deck can be removed, affording an extra large carrying space for the individual requirements of owners for touring or for commercial purposes

We have issued a new portfolio picturing the trip of the World Touring Car, with views of Australia, New Zealand, India, the Philippines, Korea, Japan and other countries, which it has accomplished. A copy of this will be sent free to any address on receipt of Burton Holmes or Frank Carpenter. Call the coupon and secure a copy of this fine volume, which is now ready.

HUPP MOTOR CAR CO., 1233 Jefferson Ave., Detroit, Mich.

THE HUPMOBILE WORLD-TOUR



The World-Touring Automobile left Detroit last November ¶ It is now in India ¶ It has traveled some 25,000 miles on land, under its own power ¶ It has crossed the United States; toured the Hawaiian Islands, and climbed to the smoking crater of the Volcano Kilauea ¶ It has penetrated the Philippine wilderness, going where no other car has ever ventured, it has climbed the steepest mountain slopes of Australia and New Zealand ¶ It was one of the very first cars to attempt an extended tour of mountainous Japan ¶ It has gone into China ¶ No other car has ever attempted a trip of the severity or duration of this tour ¶ Before the Hupmobile's return to Detroit early in 1912, it will have visited North Africa and Europe and toured the continent of Europe ¶ Many pictures, showing some of the difficulties from which the Hupmobile has emerged triumphant, are contained in the portfolio covering the Oriental section of the tour.

The Great Inventor's Prophetic Vision

Thirty-two years ago, when Edison invented the incandescent electric lamp, he saw, in his dream of the future, every home equipped with electric service. He foresaw, thirty-two years ago, that the ideal home of the future would include not only electric lighting, but also electric cooking and heating.

His dream "electric-light-for-everybody" has come true for those who will read and heed. The Edison Mazda lamp with its non-fragile filament, made from a drawn wire stronger than steel, brings electric lighting within everybody's reach. This lamp gives three times the light of the ordinary carbon filament lamp using the same current.

The carbon filament lamp was good; the tungsten lamp was better, but the sturdy Edison Mazda lamp is the last word in lighting because it combines durability with the highest efficiency known.

But perfected lighting is only one economical advance in electricity. Electric cooking has come.

The new metal-alloy "Calorite" has been perfected by the General Electric Company. The high temperature necessary for electric cooking causes other metals to oxidize and break down. But here "Calorite" is indestructible.

You can now get an electric flatiron, radiant bread toaster, coffee percolator or a complete electric kitchen range—durable, satisfying and economical.

So the prophetic vision of Edison, the great inventor, has come home for all of us. The wonderful new Edison Mazda lamp and the indestructible "Calorite" are ready for you today in your home town.

Step into the electric light Company's office or an electric supply dealer's anywhere. Ask to see Edison Mazda lamps and the G-E heating and cooking devices. If they cannot show them to you write our nearest office for complete information.

Latest Edison Mazda Lamp with Non-fragile Filament.

Looking South from a fork in the road. Canyon City in the distance.

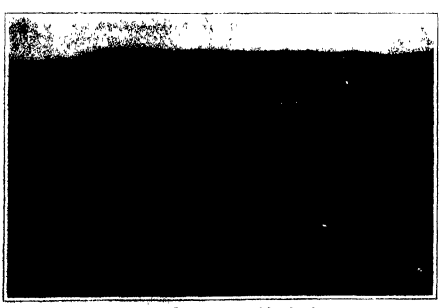
The "Sky-Line Drive"

A Road Along the Crest of a Limestone Ridge

By J. Mayne Baltimore

CANYON CITY, in Colorado, has one of the most remarkable driveways in the world. For certain features there is none other which can be compared with this magnificent drive, so unique is the whole affair.

The "Sky-Line Drive" as it is appropriately named, lies along the very crest of a long and lofty limestone ridge that rises from 800 to 1,000 feet above the surrounding plain on both sides. These limestone ridges are a characteristic feature of the region, and are called "hog-backs." This particular "hog-back" extends west and north of Canyon City, its top forming a long sky-line, and making the horizon in that direction.



Travelers traversing this remarkable "Sky-Line Road" may be seen many miles away—boldly silhouetted against the sky. The remarkably clear atmosphere of the Colorado country renders it possible to secure the smallest details—even glimpses of the sky between the spoke of the wheels, and under the horses. This famous "Sky-Line Drive" affords a most magnificent view. Canyon City lies clear out, far below the traveler, and one may look down upon it, as if looking on a colossal relief map, and almost as if poised above it in an airship.

The drive is about 25 feet wide, on an average, and it winds to and fro, and sweeps gently up and down on the narrow crest for about four miles. For the greater part of this distance the travelers are more than 900 feet above the city and the surrounding plains, to which, on both sides, the walls of the "hog-back" drop almost perpendicularly.

The beauty of the panoramic view on the other side—beyond Canyon City—is magnificent. Here valley and winding river, foot hills and mountains, have combined to form a marvelous scene filled with loveliness and grandeur.

The drive was constructed by convict labor, that made it possible to carry out such an extensive improvement. All the credit for the construction of the road properly belongs to John Cleghorn, warden of the Colorado State's Prison.

John Cleghorn, ever busy minded and far seeing conceived the idea of making of this rocky impenetrable, and dangerous ridge, a driveway. Going to Canyon City, he laid the matter before the more public-spirited citizens of that place. Of course, he had the convicts—"boys" he called them and the labor would be furnished free to the people, but it took money to pay for the necessary powder, tools, etc., and Mr. Cleghorn could not furnish any money. In less than forty-eight hours the necessary finances were provided, and Cleghorn put large gangs of convict laborers at work immediately. It took a long time to "hew out" the road. Many problems were encountered but the work was finally completed.

A magnificent view on either hand.

To-day there stands a large monument on the highest point of the road on which are carved the simple words "John Cleghorn, Sky-Line Drive." This great roadway is a public highway—absolutely free to all—pedestrians, equestrians, and every kind of vehicle, including automobiles. The driveway is one of the leading attractions of Colorado, and its accomplishment besides adding to the grand total of road improvements in the west, serves as a rich example of how means, hardly thought existing, may be used to carry out a large and a successful undertaking.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The Navy and the Inventor

IT IS a notorious fact that the inventor who approaches certain of the government departments in the hope that his invention will be investigated without prejudice and, if found meritorious, bought up at a price which will guarantee the inventor in selling his invention with the right to exclusive use, will find that he has a hard road to travel. More often than not he will experience unnecessary delays, to say nothing of considerable financial loss and ultimate disappointment.

An eloquent plea for a more liberal attitude to the inventor is made by that able officer and inventor, Rear Admiral Bradley A. Fiske, U. S. N., in the September issue of the *United States Naval Institute Proceedings*. The argument is so well put that we cannot do better than give it in the Admiral's own words. He points out that it is the duty of the navy to encourage not merely engineering skill and mechanical ingenuity, but real invention. "Knowing the brilliant original inventive genius of our countrymen, we must not stop short of a determined effort to 'ascend the highest heaven of invention.' We must hold as high an ideal in this matter as we do in the matters of strategy, tactics and engineering.

"Such a policy, wisely and energetically carried out, will have as direct and beneficial effect on the navy as our admirable patent system has on the country at large. But, to carry it out, we must first treat inventors as sane and reputable men, and recognize the fact that not only does an attempt to evade plain patent rights seem to inventors dishonorable, but it turns them to fields where they have more chance than in a battle against the government.

"Why inventors should be treated as they have been is not quite clear. Certainly it has been neither wise nor right to humiliate a class of men who have been useful in the past, and can be made useful in the future. Certainly it is not right for a great government to violate its own patent laws, and infringe patents which the government itself granted and for which it received $55 each.

"Does anyone deny that our electric lights, torpedoes, guns and engines were invented before they were developed, that they were conceived before they grew and waxed into maturity? Does anyone deny that, but for inventors, the coal and iron and brass of our ships would still be in the bowels of the earth? We all know that ideas are what have breathed the breath of life into material brass and iron. *It has already been possible for one invention to increase the hitting power of naval guns at least ten times.* Why not develop such things as soon as possible in secret and secure the military advantages accruing instead of resisting them until all the world knows about them, and then buying tremendously secret about details that any intelligent mechanic can vary in a dozen ways?"

Patent Property. What It Is. Its Protection

A UNITED STATES patent in terms purports to grant to the patentee "the exclusive right to make, use and vend" the invention therein set forth during the term expressed in the grant throughout the United States and its territorial possessions.

The wording of this grant is misleading, for the government cannot grant to anyone, any right exclusive or otherwise, to make, to use, or to sell an invention which in any way trespasses upon the prior rights of others. A patent is only *prima facie* evidence of the right to exclude others from making, using or vending the invention, and it is always open to the infringer to show that the patent is invalid, by reason of the absence of novelty, utility or invention in the patented device, or because of other statutory defenses.

Many patentees seem to have the impression that the government should of its own initiative compel the alleged infringer to cease his infringing acts. But because the patent is only *prima facie* valid, the government cannot act until proof is offered showing its validity, and for the same reason the infringer refuses to stop his infringing acts.

Having once, however, proven to the satisfaction of the courts of the government, that the patent is good and valid, protection will be at once afforded to preserve the rights of exclusion bestowed upon the patentee by its grant. This result, however, is attained in the great majority of patent suits only after the expenditure of considerable money, and the expiration of months and sometimes years of time. The owner of a patent, believing his rights to be infringed, if he decides to proceed against the infringer, files a bill in equity, the great majority of patent suits being brought on the equity side of the court. In this bill, he charges the alleged infringer with the infringement of his patent. The infringer thereupon becomes a defendant, and either denies that he has committed any act of infringement, or admitting that he has, he justifies his acts by pleading that the patent is invalid, and oftentimes combines in one answer both of these offenses.

It is not often that an infringer is discovered making the thing identically as shown, described and claimed in the patent, and the question whether the thing which he does make, constitutes an infringement, thereupon becomes an issue. Occasionally, it will be found that the infringing device is identical with that of the patent, and in such cases, the validity of the patent will constitute the issue. In this attack upon the validity of the patent, it may be shown that the invention was not new at the date of the patent, that it was not the invention of the patentee, or that it had been in public use and on sale more than two years prior to the date of the application on which the patent was issued.

The preparation of and presentation to the court of the evidence on behalf of the patentee, and the alleged infringer, is what involves the extraordinary expense incident to patent suits. The decision in such cases generally rests upon the testimony of experts. Those who testify for the patentee, explain to the court the construction, organization and mode of operation of the invention of the patent, and comparing the same with the thing or things made by the alleged infringer, and express their opinion as to whether or not such things embody the patented invention. The experts for the alleged infringer thereupon place their interpretation upon the patent at issue, and upon such other and prior patents, both domestic and foreign, which may be relied upon as showing either that the patent in suit is of restricted scope, and not infringed by the defendant's manufacture, or is completely lacking in novelty and invention. This evidence is taken before an examiner, and the cost in the average case approximates $175 per day. A further expense arises from the necessity of printing the evidence for presentation to the court. This entails an expense of from $1 to $1.25 per printed page. The expense may be greatly increased by the introduction of irrelevant and immaterial testimony, and also the placing upon the record of extended and oftentimes unwarranted objections of counsel, all of which must be taken down by the examiner and presented to the court, for under the present rules he cannot pass upon the admissibility of evidence.

It has been stated that the cost of taking the testimony and presenting it to the court in the famous Selden case, was upward of $150,000. In that case, after long years of litigation, while the patent was not invalidated, the defendants ultimately escaped the charge of infringement. Fortunately for the owners of that patent, however, it was *prima facie* of such a formidable character, that long before the final adjudication, they had succeeded in collecting from the manufacturers of automobiles, thousands of dollars as royalties. The brief in the Selden case consisted of two large octavo volumes of at least 500 pages each, and could have been produced only at considerable cost.

Another famous case, wherein the city of New York was sued, for infringing a patent covering an automatic relief valve for fire engines, was fought through the courts for a period of twenty years, from final adjudication, an estimated cost of half a million dollars, and was finally decided in favor of the city on the ground that the patent was invalid, the invention having been proven to have been in public use two years and eleven days before the patent was applied for.

The right of exclusion, however, which the government bestows upon a patentee, and which costs so much to enforce, has proven in many cases to be an extremely valuable right; has enriched many inventors, and constitutes the foundation of vast business enterprises, and to this right, largely, is due the wonderful progress of the civilized world.

Build a New Patent Office

THIS is not the age of sentiment or conservatism. A costly new building twenty stories high, for example, must be demolished to make room for one forty stories high which will yield a correspondingly higher profit.

The SCIENTIFIC AMERICAN has repeatedly called attention to the urgent necessity for a newer and greater Patent Office. An article was recently printed giving the facts about the over-crowded and obsolete building now occupied by the Commissioner of Patents and his force of one thousand subordinates. This article was prepared for the purpose of showing the inventors of the country and the manufacturers and merchants that they have been woefully negligent in not insisting that Congress take some steps to house the Patent Office decently. Their negligence, however, has been nothing to that of Congress itself, for the inventors, manufacturers and merchants cannot acquaint themselves at first hand with the conditions at Washington without considerable loss of time and money, while Congress, on the other hand, has been repeatedly and persistently importuned in the matter, and every member of Congress is in a position to thoroughly satisfy himself on the subject.

Ever since Commissioner Moore first took the office he now holds he has been reminding Congress that the Patent Office is in need of legislative action to give it larger and better working quarters. Bills have been introduced carrying the necessary appropriations and arguments have been made in the committees, all to no avail.

The surprising thing about this dilatory policy on the part of Congress is the fact that the Patent Office, which is one of the very few self-supporting branches of the government, has a sufficient surplus in the Treasury to defray all the expenses of a new Patent Office building, including the ground to build it on. This surplus, which amounts to something like seven millions of dollars, represents a net profit over all the expenses of running the Patent Office since it was first instituted. A pretty comfortable margin of profit, indeed, when one considers the enormous expenses that the office is under to get competent examiners and to turn out high-grade printing, photolithographing, etc. What private enterprise whose net profits were seven millions of dollars would be content to occupy a building wholly inadequate for its needs?

Congress has no right to require clerks to work in dark, crowded rooms, where health is endangered and ambition thwarted. Disagreeable surroundings have a physical and mental effect on workers. Ask any housewife whether she can work or live happily in an untidy house. In such a household one would look for disease, sloth and uncleanliness. Is it not equally discouraging for men and women to work in a room where documents and books are piled high, accumulating dust, and in a semi-chaotic condition, just because there is no room for them to be properly cared for?

Congress does not have to appropriate a single dollar for the building of a new Patent Office over and above the surplus already earned by that bureau. A bill should be passed early in the coming session giving relief to the Patent Office. Every session that sees nothing done in this regard increases the gravity of the situation. The Patent Office records are of the utmost value. Their loss or destruction would undermine the foundations of the entire business world. They could never be replaced. The security of countless millions of dollars rests in their preservation. The Patent Office models, too, lead a precarious existence, and some effort should be made to give them proper storage facilities until such a time as they can be properly housed in the new Patent Office.

Some day when it is too late, perhaps Congress will be forced by the clamor of public opinion to allow the use of the Patent Office's money for a new building. Why not take action now, while there is yet time to save these priceless records?

Edison's Impressions of European Industries

[That the powers of observation and analysis, which have contributed so largely to Mr. Edison's success, were used to good effect during his recent lengthy tour of Europe, is evident from the following "impressions" which were given, during a recent interview, to a representative of the SCIENTIFIC AMERICAN *—ED.]*

Q. WHAT feature of the industrial situation in Europe has made the deepest impression on your mind, Mr. Edison? Ans. I am free to say that among the countries which I traversed, Germany has left by far the deepest impression on my mind, particularly as regards the enormous strides which she is making in the development of her industries and the extension of her foreign trade.

Q. What do you consider to be the fundamental secrets of Germany's success? Ans. Her intelligence, her patience, her industry, and her appreciation of the value of co-operation. In the development of their industries and commerce, the Germans are a united people. They are working upon a carefully co-ordinated plan, having for its ultimate object the capturing of the major portion of the world's commerce, and in this effort they have the great advantage over other countries, and particularly over the United States, that they have back of them the assistance and prestige of the German Government.

Q. What is the German attitude toward the inventor? Ans. I find that the inventor has better opportunities in Germany than he has in the United States, and this for the reason that any factory which manufactures articles of the character covered by his invention is encouraged to take hold of it, because of the financial assistance which it can secure from the great promoting banks, of which the Deutsche Bank, one of the largest in the world, is the most notable example. If an inventor brings a new invention to a factory, he is not likely to be turned down because the company is without the necessary capital to cover the cost of its manufacture and exploitation. They can present the invention for the consideration of a corps of engineers and auditors, which is maintained for that special purpose by the Deutsche Bank, and if they pass favorably upon the invention and upon the standing of the manufacturing company, the company will be financed to such an extent as the bank may think proper. Now we have no such promoting banks in this country. The inventor must either endeavor to interest the manufacturer by personal application, or he has to fall back upon the professional promoter, who too often is quite unreliable.

Q. To what extent does the German Government stand back of the patents which it grants? Ans. Although the German Government does not guarantee the validity of the patent, it practically arrives at the same result by making it a very difficult matter to obtain a patent. In the first place, the invention must be quite meritorious. The inventor will have a long fight in the Patent Office, in which the question of its priority will be most carefully investigated. But when he once obtains his patent, it is a patent, and after a certain number of years it cannot be disputed. The German patent possesses the greatest value, and if an American inventor has a really meritorious invention, I would advise him to fight the German Patent Office to the very last ditch. If his invention possesses distinct merit he will be treated fairly and will get his patent. Before leaving the subject of patents, I may say that I do not think the corporations follow the practice of buying up patents simply to pigeon-hole them, and I do not believe that this is done in the United States as much as some people imagine.

Q. Have they a "trust" problem in Germany? Ans. Regarding German business methods, particularly among the corporations, I find that though they do not have "trusts," as we understand the term, in Germany, they have what is practically the same thing. They have pools or cartels, which set the price that all the people, or a portion of the people, as the case may be, engaged in any industry, shall ask for their goods. They have a central agency; but over this the Government exercises no supervision, and indeed, it does not prevent the formation of these pools, realizing that destructive competition will never build up German trade. Take note, however, that these cartels do not strangle the small man. They take him in, or, if not, do not close the door of equal opportunity.

Q. To what extent is American machinery used in Germany? Ans. Every American manufacturer who visits Germany will be at once impressed with the widespread and increasing use which is being made by the Germans of American machinery—machinery either of American make or American design. When they take American designs as their models, they make very little, if any, improvement therein. Their labor costs very much less than ours, and therefore there is not the same incentive to design automatic machinery, and, very wisely, they leave this particular field to the Americans. When we have improved our machinery, they come over and buy it, and after they have tried it out and found it to be satisfactory, they duplicate it. It would be foolish for the Germans to go ahead and try a lot of experiments in making automatic machinery, when they know that the Americans are bound to do it anyway, and do it better than they can. Undoubtedly, Germany has benefited enormously from the introduction of American tools and American methods, but the debt is not altogether on their side. Germany is a great scientific nation, continually engaged in scientific research, and as the result of this, we not only get from her a large number of scientific discoveries which we apply to our industries, but she also furnishes us with an enormous amount of chemicals for use in our various industries. The German, on account of his patience and other valuable peculiarities, is well equipped for the task of working out tedious and involved processes—something which the average American takes to very unkindly. The American wants quick results. He is forever striving to cut down the time element, and hence, as I have already stated, he is pre-eminent in the field of automatic machinery. But for the task of developing intricate processes, involving much time and extraordinary patience—processes which, as in chemistry, involve many unknown reactions—the German is wonderfully well qualified.

Q. Does German superiority extend beyond the chemical industries? Ans. It must not be thought that German advance is restricted to the field of the chemical industries. Not only is she already pre-eminent here, but she is threatening our supremacy in many other branches of manufacture. The danger for us lies largely in the raw methods of interference by the Government and the weighting down of business with cumbersome and little-understood laws, some of which are enforced and others not. Furthermore, while political interests in Germany are universally friendly to trade and commerce, in this country politics is one of the heaviest burdens that industry and commerce have to carry. Here in America we have no mercantile marine to carry our goods, and, even if we had, we possess no banking facilities in outside countries to assist the exporter in selling the goods. We have no corps of young men specially educated to go out to foreign countries and hustle for business. A large and rapidly increasing part of the products which I saw in course of manufacture and being shipped from German factories was not for use in Germany, but in countries outside of its borders. Unless business in the United States is put on a more satisfactory basis, and is rid of the present interference by the politician, Germany will be in such a strong relative position that she will win out against us right down the line.

Q. Do you think the German dream of commercial supremacy will be realized in the near future? Ans. Personally, I do not believe that Germany will attain pre-eminence in the commerce of the world as rapidly as some people think. To-day, Great Britain is the leading nation in manufacture, engineering, and shipping, with all that this implies. She has an enormous, well co-ordinated and harmonious empire, and at present she has the great advantage that she holds the leading position in finance. Germany does not hesitate to let the world know that she aims at the high position now being held by the English people as the leading commercial nation, and in the race for supremacy she is going, just now, very much faster than any other country. She is giving England a great run, and, judging from present conditions in the two countries, it looks as though in time she should reach the goal—but not just yet.

Q. Do you see any signs of decadence in Great Britain? Ans. I do not think that the English nation is decadent. Far from it. But I do consider that there are conditions in the English industries which, unless they can be changed, must lead to commercial decadence. I refer to the very serious question of her union troubles. In Germany I saw a man working three planers; I understand that in England the unions will not permit such a thing to be done. All through the German shops, any man will work as many tools as possible. All the factory operatives are on piece work. This, I believe, is not permitted in England. Hence the Germans can manufacture goods of the same quality as the English very much more cheaply; export them in their own ships, and finance the sale of them over a long period—and I can see but one ending to a competition of this character. Furthermore, the English business man does not come as early to his work, and he leaves it earlier than does the German.

Q. This great increase in the German navy—does it mean war? Ans. I do not believe that this commercial rivalry between the two nations will lead to war. Emperor William is a pretty good business man, and he would be very foolish, now that German commerce is spreading so rapidly over the world and German ships are found upon every trade route, not to take the proper measures to insure these enormously valuable and growing interests. The best insurance for a large foreign trade is a navy adequate to its defence. I do not think that the Emperor and his people are building the big German navy with any express intention of fighting England or any other nation. Germany in building her navy, has simply given notice to the world that she is a big manufacturing nation and that she is going to find a market for her goods in every corner of the earth. Therefore, she is going to see to it that no more countries shall be shut up against her commerce. This, of course, is making Germany unpopular, but I cannot see that her attitude is anything but perfectly reasonable and proper.

Q. While in Germany did you look into the matter of municipal government? Ans. I wish to pay tribute to the high state of perfection to which they have carried their system of municipal government. In the first place, they appoint a very high-class man for mayor, and he holds this distinguished and greatly honored position for life, or until such time as he is retired. One direct result is that these mayors are all the time trying to better the government of their cities, to bring in new industries, and to improve them artistically and otherwise. I had the pleasure of meeting six or eight of the mayors of different German cities. They were certainly the very finest type of men. Most of them spoke English without any accent whatever, which greatly surprised me. Furthermore, their knowledge of engineering was of quite a high character. I could not learn that there was any graft whatever in any of these German cities.

I have spoken of the artistic improvement of the German cities. The same spirit is observable in France, and generally in such European cities as I visited. Ugly or unsightly buildings or freak buildings of any character whatsoever are not allowed to go up. They carry this principle to such an extent that in Paris where they have a great many double-deck buses run by gasolene, an order was recently promulgated that after a certain date no more double-deck buses must be used in Paris, for the reason that they were inartistic in appearance. It was understood of course, that the double-deck buses were more profitable, but Paris would not permit the corporation to earn its greater dividends at the expense of the general artistic appearance of the streets, although the city, I understand, is a partner in the enterprise.

Q. Naturally the lighting of European cities interested you, Mr. Edison. What did you observe? Ans. Speaking of the conditions in the cities, I noted that the lighting of the leading European cities does not compare with that of New York. Berlin and Paris are about equally well lighted, but Berlin is continually putting in more light, and before long she will greatly surpass Paris in this regard. Night life in Berlin is increasing very rapidly. It was observable that throughout Europe the night life is on the increase in those cities which have cheap water power, and there seems to be a correlation between the night life and the industrial activity of the people. In towns where the people have cheap and plentiful light, they keep later hours, and this seems to have the effect of mitigating the phlegmatic character of their temperament. In Switzerland, for instance, I have seen two towns which were of the same size and generally alike in their conditions, with the exception that one, possessing suitable water power, was well lighted at night, and the people of this town instead of going to bed at eight o'clock, were on the streets up to ten or even later. This town had decidedly a smarter appearance. More buildings were going up and there was a general air of enterprise. Many people sleep too long and over-sleeping, contrary to commonly accepted ideas, so far from being refreshing, renders one sluggish and slothful. Hard work, work in which you are thoroughly interested, is more stimulating and refreshing than sleep for sleep's sake.

For thirty years I slept only four hours a day and I have had lots of assistants at various times that did the same thing. We all felt fine.

Needed Reforms in Patent Procedure

By Melville Church

WHILE our patent system has commanded the admiration of the world and has had many imitators, it is certainly susceptible of much improvement, as any one familiar with the details of its workings will testify.

The delays and expense involved in securing a patent, against the opposition of an adverse claimant, the enormous cost and delay involved in attempting to enforce a patent when granted, and the lack of conclusiveness of the judgment finally secured, save in the particular jurisdiction in which it is rendered, call loudly for reforms in procedure.

Under the law, as it now stands, if an applicant for a patent encounters in the Patent Office a rival claimant to the same invention, a proceeding is instituted, known as an interference, for the purpose of determining the question of priority of invention as between the two claimants

Opportunity is given each claimant to adduce evidence in support of his claim and, when the evidence is all in, the case is first argued and submitted to an officer, known as the Examiner of Interferences, for determination The Examiner of Interferences reads the record of testimony (which, by the way, is apt to contain much irrelevant and immaterial matter because of the uncontrolled way in which it is permitted to be taken) and, after from two to four months' delay, renders a decision awarding priority to one or the other of the parties, and fixes a limit of appeal from his decision Within such limit, which is never less than twenty days, the unsuccessful party may appeal to the Board of Examiners-in-Chief, a tribunal of three judges This Board sets a day of hearing one or two months distant and, on that day, there is another argument and submission

After a period of from two to six months, the Board renders its decision and sets a limit of appeal of not less than twenty days The party unsuccessful on the last appeal may then appeal to the Commissioner of Patents, in person If he does so a day of hearing will be fixed from one to two months distant, when there will be another argument and submission Within a period varying from one to four months, the Commissioner will hand down his decision and the party aggrieved thereby may, within forty days of the entry of the judgment give notice of appeal to the Court of Appeals of the District of Columbia, and, within forty days after said notice, may docket his appeal in such Court of Appeals The last named court is a tribunal of three judges, sitting in Washington, and bearing the same relation to the Supreme Court of the District of Columbia and to the Patent Office that the United States Circuit Court of Appeals for any one of the nine judicial circuits bears to the Circuit Courts of that circuit

If the appeal to this Court of Appeals is, for instance, docketed in May, it cannot be heard for six months, or till the November term following When the court hears the appeal taken to it and hands down its decision, it might be thought that the controversy would be settled but this is not the case The decision of the Court of Appeals is not final as to any question litigated before it and the unsuccessful party has still the right, under the provisions of Section 4915 of the Revised Statutes, to file a bill in equity against his so far successful rival, in the judicial district in which the latter may be found, asserting anew his claims to priority In this bill in equity proceeding the plaintiff is entitled to make an entirely new record of testimony and may again call all the witnesses he called in the Patent Office proceeding and as many more as he can find, with, of course, the privilege of the defendant to do the like It will take the better part of a year to get this equity case ready for hearing and, after it is heard the Circuit Court will probably hold it from two to six months before deciding it The defeated party may then appeal as a matter of right, to the United States Circuit Court of Appeals for that particular judicial circuit, at any time within six months of the entry of the decree in the Circuit Court.

After the docketing of this last appeal it may take six months more before the appeal is heard and several months more may elapse before the appellate court hands down its decision finally setting the question of priority at rest.

It will be seen from the foregoing recital that a priority contest may involve the taking of testimony in the initial Patent Office interference proceeding, a first hearing and judgment by a tribunal consisting of one person, a review of that judgment by a tribunal of three, a further review by a tribunal of one, and a still further review by a court tribunal of three, all upon the same record, followed by a further review, on an enlarged or an entirely new record, by another trial court and a final review by another appellate court

Even if the judgment of all the tribunals to which the controversy is submitted be in favor of the same applicant, still, before the final judgment is arrived at, he must submit to being dragged through this long and devious course of litigation, at ruinous expense, before his right of priority can be said to be firmly established.

There is absolutely no necessity for such protracted litigation. The inordinate number of appeals permitted serves no useful purpose whatever The submission of the controversy to a single tribunal of first instance in the Patent Office, with the allowance of one appeal to an appellate tribunal outside of the Patent Office—the Court of Appeals of the District of Columbia, for instance—with power in that court to make a judgment that shall be final and conclusive, as between the parties and those claiming under them, as to every matter involved in the litigation, would seem to be a complete and satisfactory solution of the problem and tend to the furtherance of the cause of justice

There is no more reason for providing a long series of tribunals to try out an applicant's right to priority of invention over a rival claimant than there is for determining, in the same way, any other matter of private right.

A claimant to a piece of land containing a gold mine brings his action of ejectment in a Circuit Court of the United States (the requisite diversity of citizenship existing) against the person in possession, and, if judgment goes against him, he may, by writ of error, remove the case to the United States Circuit Court of Appeals for that circuit, and if the judgment below is there affirmed, the litigation ends.

But, under existing law, an applicant for a patent may contest with another a claim to priority of invention not through two only, but through six different tribunals.

The right to invoke the aid of so many tribunals works a hardship upon both the inventor and upon the public. Experience has shown that the final judgment reached after submission of a case to two tribunals is as liable to be correct as that reached after submission of the same case to six different tribunals.

An inventor enamored of the value and importance of his invention will, of course, pursue his claim through as many tribunals as the law provides, or until his money gives out, but it is no real kindness to him to afford so many additional outlets for his enthusiasm. On the other hand, it would seem to be contrary to public policy that the judicial machinery of the government should be susceptible of being put into motion so many times for the protection of this particular kind of private right.

The first great reform our patent system needs is, therefore, the cutting down of the number of appeals in priority cases.

But the trials of an inventor by no means end when, after undergoing the delay and expense consequent upon the vast number of appeals provided, he at last secures his patent If his ancient adversary, who has contested his right while he was getting a patent, shall continue to practise the patented invention, he must, under the present state of the law, bring a new suit against him for the purpose of stopping him This usually takes the form of a suit on the equity side of a Circuit Court of the United States, in which he asks for an injunction and an accounting of profits and damages. In such a suit, the defendant may challenge the novelty and utility of the patented invention, the identity of his appliance with that covered by the patent—though it may be the same appliance that was involved in the prior interference proceeding—and about the only thing he may not do is to again assert his claims to priority of invention.

When this suit in equity is, by the pleadings, brought to an issue, time is given for the taking of testimony by the plaintiff and defendant, respectively. The witnesses examined are not produced in open court before the judge, so that the latter may observe their demeanor while testifying, and pass upon the competency, relevancy or materiality of the testimony offered, and generally control the proceedings, but, as in the Patent Office proceeding, the testimony is introduced in the form of depositions taken before notaries public, or standing or special examiners of the court, who have no power whatever to pass upon the competency, relevancy or materiality of the evidence offered, or otherwise to control the proceedings, but who simply act as recording officers, taking down everything that is offered by way of testimony, as well as the objections and arguments and irrelevant remarks of counsel, and returning all to the court for the latter's examination. Because of this lack of restraint in the production of evidence, the depositions are extended and long drawn out, some of them, especially the depositions of experts, continuing for weeks and even months, until the record, as one of the federal judges has said, looks as though it were afflicted with elephantiasis.

When it is remembered that good patent lawyers charge from twenty-five to one hundred dollars a day for their services and that good experts charge fifty

(Continued on page 464.)

The enormous record of the Selden case.

"The evidence on the subject of operativeness is the most flagrant example of unsupervised testifying I have ever seen or heard of Whether in 1906 Exhibit 47 was any better than scrap, whether Exhibit 89 would start on flame ignition, whether Exhibit 132 showed diagrams revealing volume or pressure constant, were perhaps interesting, but unimportant questions They raised a false issue, over which months of time and volumes of print have been expended" (Judge Hough, in the Selden case)

Campbell vs. the Mayor, etc., of the City of New York.

This suit on the Knibbs patent for a fire engine relief valve was filed originally in 1877. The patent was sustained in the lower court and a master's hearing ordered This photograph relates to the master's hearing On the extreme right sits Judge Joseph M. Duel, now Judge of General Sessions Court, New York, the master appointed by the court Next is Samuel R Betts, counsel for the defendant, Harvey Hadlock and Mr Wood (both now dead) of counsel for complainant, Mr Washburn, executor of the estate of the complainant. The books forming the background are the entire records of the New York Fire Department at that time, secured by *subpœna duces tecum*, and stacked up to form background. The legal proceedings continued over a period of twenty years.

The French Competition for Military Aeroplanes

Some of the Leading Machines and Tests They Successfully Fulfilled

ALTHOUGH the United States was the first government to purchase an aeroplane for military use, the much more rapid development of the heavier-than-air machine in France led to a quick appreciation of its possibilities for scouting above both land and sea, and the government promptly offered generous prizes this year for the fastest military aeroplane which should fulfill certain conditions. These were that the aeroplanes should transport a total useful load of 660 pounds (made up of 3 men, supplies, etc.) at the rate of at least 37½ miles an hour without a stop throughout a distance of 186 miles. Only machines which were not eliminated in the strenuous preliminary tests were eligible to compete in the final race. To the constructor of the winning machine was to be awarded a prize of $20,000 and an order for ten similar machines at a price of $8,000 each.

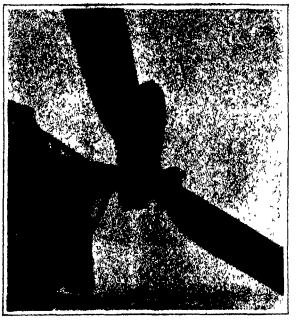
The preliminary tests consisted of about a half-dozen flights from the aerodrome at Rheims to certain specified points where the machines were obliged to land upon meadows, stubble and plowed fields, and to start therefrom again, each time carrying a full load of 660 pounds. There was also a "climbing" test in which they were compelled to ascend to a height of 500 meters (1,640 feet) in 10 minutes, while carrying a full load.

In addition to the successful carrying out of these various tests, the following hints were given as to what was desirable:

That the observer's field of vision should not be interfered with by any part of the machine.

That double control should be fitted, or, at least that the pilot should be capable of being relieved by his assistant while in flight.

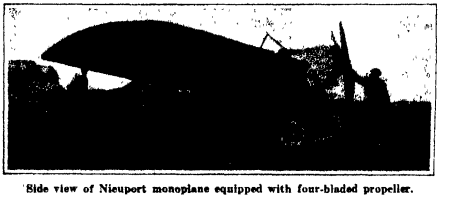
That machines should be capable of starting without outside assistance.



This competition has undoubtedly had a decided effect in stimulating invention and the perfecting of machines. For example, two triplanes made their debut in it, whereas both the Farman brothers brought out biplanes with offset upper planes—a system originated in France by Goupy about a year ago, and which has also been used by Mathew B. Sellers in this country with his multiple-surface, low-powered fliers. The planes have a better lifting effect when they are offset in this way. Henry Farman also entered a biplane the upper surface of which extended beyond the lower one at each end, having a spread of 67 feet.

Instead of obtaining the increased lift necessary by increasing the surface or offsetting the planes, most of the monoplanes effected this by increased power, although the wings were generally somewhat larger than usual. The Nieuport monoplane is shown in one of our illustrations, while another gives a rear view of the novel "armored" Antoinette. This machine was described fully in our last issue. It is the first monoplane constructed and flown successfully with rigid wings without guys, a construction indicated by us in the SCIENTIFIC AMERICAN of October 22nd, 1910. The Nieuport monoplane is noteworthy as being the fastest aeroplane in the world. Its wide blunt body, completely covered with cloth, slips through the air with a minimum of resistance. The machine is shown fitted with a four-bladed propeller, which seemed to be the vogue in this contest. Another aeroplane to use this type of propeller, which long ago was shown in Maxim's experiments to be not so efficient as a two-bladed one having the same blade area, was the Breguet biplane. The body portion of one of these novel machines is shown being towed behind an automobile. They are far simpler in construction than any other biplane, and can be quickly put together or taken apart. Complete details of the chassis will be found in SUPPLEMENT No. 1873. A photograph showing a Breguet biplane being assembled was published in SUPPLEMENT No. 1867. One of the latest inventions of M. Louis Breguet is the propeller with pivoted blades shown herewith. The advantage of this mounting lies in the fact that the propeller blades can adjust themselves to vary the pitch. When starting, the normal pitch is too flat, but by having the blades hinged they will swing forward automatically in proportion to the resistance offered by the air, thereby altering the pitch and thus accommodating themselves to the varying requirements.

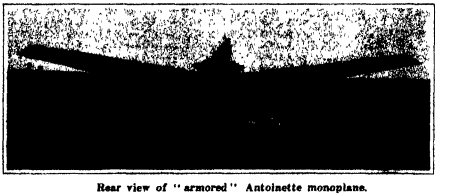
Thirty-three machines were entered in the contest altogether, but some of these failed to materialize, so that there were actually but 28. Of these 19 monoplanes and 18 biplanes; 3 monoplanes and 5 biplanes were selected for the final speed test on November 4th. The results of this test are not available at the present writing, but it is probable that the prize went to the Nieuport monoplane piloted by the American Weymann. This machine surprised everybody by the success with which it landed and restarted from plowed fields and rough ground. Its central skid and flat leaf spring connecting the two wheels worked exceedingly well under these trying conditions.



There were three fatal accidents incidental to the carrying out of these tests. One occurred on the ground, a mechanic being struck by a rapidly revolving propeller and sustaining injuries from which he died. Lieut. Conneau, the winner of all the big circuit races last summer, also had a bad fall in his Blériot and broke his legs. René Level fell in his Savary biplane and was killed as a result of engine failure. He struck some wires in a forced descent of 500 feet and his spine was broken in two places. Jean Desparmet, pilot of a 140-horse-power Blériot monoplane, was the third man to lose his life, and the thirteenth military aviator whom France has lost. He was flying splendidly in perfect weather, when his monoplane suddenly dived to the ground from a considerable height.

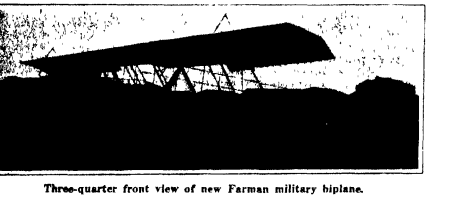
When we consider that France has over 200 military aeroplanes, and that numerous flights are made daily by her military men, the number of fatal accidents is not so great as might be expected. The military aviators take great risks to demonstrate the practicability of the aeroplane in all kinds of weather, and many of these, for their daring and courage, have received the Cross of the Legion of Honor.

The Breguet triple-bladed flexible propeller.

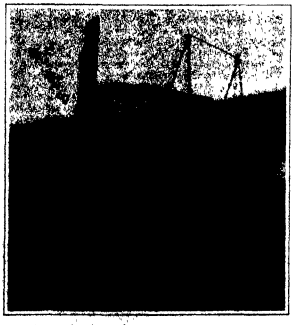


One blade is shown pulled forward. This flexibility prevents breakage of the blades, in turning, owing to gyroscopic force.

Side view of Nieuport monoplane equipped with four-bladed propeller.



Body of a Breguet biplane towed behind an automobile.

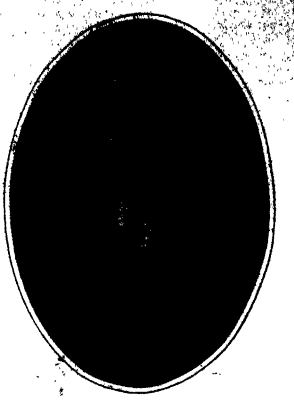


Rear view of "armored" Antoinette monoplane.

This machine is noteworthy on account of the complete lack of guys above and below the wings.

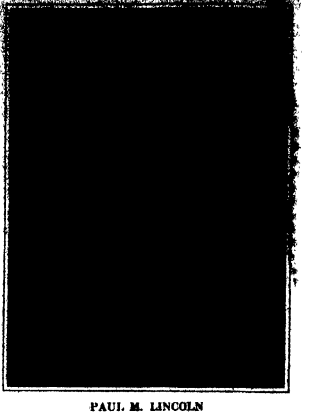
Three-quarter front view of new Farman military biplane.

Note the offset planes and the inclined fuselage projecting out in front. Behind M. Henry Farman there are two seats in tandem for passengers.



Front of latest Blériot military monoplane.

Note the "Normale" propeller and triple wheels as well as the fairplane winglet in the side of the body.



THE FRENCH COMPETITION FOR MILITARY AEROPLANES

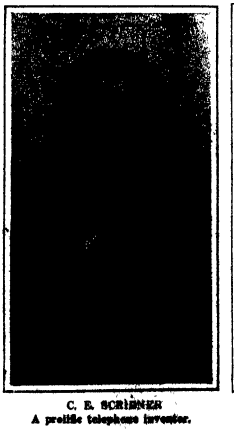
Invented a synchronizer.

The Industrial Corporation and the Inventor

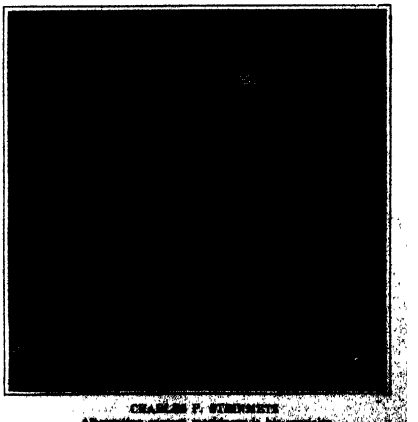
EVERYONE who has been intimately connected with any large manufacturing companies, especially those manufacturing machines such as lathes, planers and other tools, will recall the activities of certain *attaches* of the companies who were recognized as employed for the specific purpose of suggesting and devising improvements in the machines These inventors spent many hours daily in the shops seeking here and there the improvements which might place the machines produced by the company in a better position for competition with those of other makers Many of the large industrial corporations of the country have intimate connection with groups of inventors especially skilled in certain directions

From the foregoing it is readily appreciated that the problems presented to many of our industrial organizations necessitate the employment by them of men of scientific and technical training, graduates of our colleges and technical schools, or those trained in the school of experience, who being presented with a problem and having knowledge and originality, can, if the occasion demands, create inventions It is not surprising, therefore, to find that to these men, the identity of whose inventions is often lost in that of the organizations of which they are a part, we owe many of the improvements which mark our industrial progress



The employment of technically trained men by the large companies will be found extending throughout many arts, but it is natural that it should be found especially emphasized in the electrical and metallurgical developments to which much of what follows will be confined, serving to illustrate the importance, in fact the practical necessity, of the inventor as an adjunct to large industrial corporations While it is impossible within the limits of this article to enumerate all such that are worthy of mention, a few illustrative cases will serve to indicate how greatly we are indebted to these men for the advances made in the arts.

The metallurgical art furnishes many interesting examples of difficult problems met and solved by men of genius in the line of their employment. To illustrate, it would perhaps scarcely occur to one not confronted by the fact in actual working, that the variable quantity of moisture in the atmosphere might produce a deleterious effect in the operation of blast furnaces and steel converters which, as is well known, consume large quantities of air, the former in the process of reducing the oxides of iron, and the latter in the oxidation of certain impurities Nevertheless, it is a fact that the presence of moisture in appreciable quantity is injurious because it absorbs heat due to its decomposition at high temperatures, and moreover, the variations in the quantity of moisture produce corresponding irregularities in the quality of the product It is estimated that between sixty and two hundred and forty gallons of water per hour may be delivered to a blast furnace in this manner. The effect can readily be appreciated Since the air must be supplied under pressure and in enormous quantities, the use of chemical agents for removing the moisture does not offer a ready solution of the problem. The difficulty was effectually solved, however, by James Gayley, who devised a system wherein the air, under pressure, in its passage between the blast engine and furnace or converter, was cooled in successive stages by contact with a series of pipes arranged to conduct a refrigerating fluid across the direction of the air current. The air before being fed to the furnace or converter was, in this way, cooled to a temperature at or below zero degree Centigrade, which caused the precipitation of the greater portion of its moisture. The water of condensation was then drawn off through pipes provided for that purpose In this way, substantially dry air was provided, the amount of moisture being practically uniform from day to day.



To William R. Jones we are indebted for a method of cheapening the cost of production of Bessemer steel. Prior to his invention the indirect or cupola process was generally used in this country. This process consisted in running molten metal from the blast furnace into pigs; these after cooling were carefully assorted, broken up and remelted in cupola furnaces from which the molten metal was conveyed to the converter for conversion into steel. Many attempts were made to eliminate the costly intermediate steps by supplying the converter direct from the blast furnace, but the fluctuations in the chemical composition of the metal from the blast furnace were such as to render the final product of the converter of uncertain character. The necessity for obtaining a uniform product will readily be appreciated when we consider the annual fatalities due to broken rails alone. The

ELIHU THOMSON
Notable for his work in electric welding.

C. E. SCRIBNER
A prolific telephone inventor.

CHARLES P. STEINMETZ
Alternating current machinery is his specialty.

[illegible] to [illegible] a stopper at [illegible] the [illegible] the [illegible] the idea of [illegible] [illegible] [illegible] between the blast [illegible] [illegible] [illegible] which should receive the [illegible] [illegible] from the blast furnaces and maintain [illegible] [illegible] in such quantity that its average composition would not be materially altered by the addition from time to time of much smaller quantities of variable composition. From this mass of substantially uniform composition the converters were supplied, and the resultant steel product derived was substantially uniform. This invention illustrates in a forceful way the familiar fact that often the simplest expedient reveals the highest degree of invention, and also shows what small differences often lie between success and failure, for the chief difference between Jones' device and prior known devices resided in the size of his reservoir whereby he was able to obtain metal of substantially constant composition.

Perhaps nowhere is the efficiency of organized effort better illustrated than in the advances made in the arts by the engineering departments of the electrical companies.

In the telephone art appear such names as Scribner, a prolific inventor who has done much to standardize telephone installations, and Dean and Dunbar, to whom is due much credit for the development of the so-called two-wire switchboard system whereby the third wire of previous systems is dispensed with. Worthy of special mention, also, is the invention by Scheisinger of the four-relay cord circuit, a form now widely used in many telephone systems, in which its use is held to be practically indispensable. Entitled to special note also is the invention by White of the so-called solid back transmitter, which has been a standard for many years.

Charles P. Steinmetz, head of the electrical engineering department of one of the large electrical companies, has done much constructive work in the electrical art, having made many important inventions in alternating current motors, generators, converters, regulators, lighting and the like, but perhaps his greatest contributions to the art are his remarkable mathematical treatises on the subject of alternating current phenomena, which are standard text books in electrical engineering, as well as books of reference for the practical engineer.

The mathematical accuracy of physical laws of action is well exemplified in the phase-transformer, independently invented by Steinmetz and Charles F. Scott, a prominent engineer of another company. This device, though structurally simple, would not have occurred save to one skilled in the mathematics of mechanics, while the value of the invention lies in the fact that it enables current to be transmitted of a number of phases capable of the most economic transmission, and then, by the use of the transformer, to be changed to a number of phases best adapted to local needs, as from a three-phase transmission line to a two-phase motor. The transformer consists merely of several primary and secondary coils so connected and inductively arranged that the electromotive forces in the primary circuit are resolved into components corresponding to the number of phases desired, thus inducing electromotive forces of the same number of phases in the secondary coils, which supply the secondary circuit.

Dr. Elihu Thomson, one of America's leading authorities on matters electrical, is regularly employed by a large electrical company. His work on high potential and high frequency apparatus and also on electric welding is notable.

Many important inventions have been made in electric meters by Schellenberger, Pratt, Tingley, Conrad, Davis, Bradshaw, and other engineers of the various companies, while the synchronizer of Lincoln, which enables the phase and frequency of an incoming generator to be determined preliminary to connecting it to line, is also a valuable addition to its art.

Of particular importance among regulators for electric systems is the invention by Tirrill of the regulator which bears his name. The characteristic which renders this regulator of particular value is the quickness with which it acts to control the generator voltage responsive to changes in the load on the line.

Much progress has been made by the engineering corps of the electrical companies in the electrification of railways and interurban lines. Prior to the present decade direct current only was available for railway purposes. This could not be economically employed on the longer lines owing to the difficulties of transmission at ordinary voltages and the heavy sparking at the brushes encountered when higher voltages were used. On the other hand, alternating current, which can be efficiently transmitted to relatively great distances at ordinary voltages, could not be employed because no thoroughly satisfactory variable speed alternating current railway motor had as yet been devised. Within the past decade, however, not only has the length of direct current systems been increased by the employment of interpole generators and motors of efficient design, which has rendered the use of much higher voltages possible, but also the problem of the alternating current variable speed railway motor has yielded to the ingenuity of engineers in charge of construction work of this character, and successful variable speed alternating current railway motors are now in operation on many of our roads, notably the New York, New Haven and Hartford. Prominent among the inventors of this country in the development or the alternating current railway motor are Lamme, Alexanderson and Milch, while abroad much valuable work of a pioneer character has been done by such prominent engineers as Winter, Eichberg, Latour, Derl, and others.

Few fields have claimed more attention recently than that of lighting, and many important improvements in this art have resulted from the extensive experiments conducted by the well-organized departments of the various electric companies. Just and Hanaman have done much to develop the tungsten light, and Kuzel also has rendered efficient service in this line, the latter having invented the colloidal process for the manufacture of tungsten filament. The importance of the tungsten light will be readily appreciated from the fact that for the same amount of current it furnishes substantially 100 per cent more light than the ordinary carbon lamp. Prominent in the development of the flaming arc are the names of Steinmetz, Dempster and Ladoff, while the names of Steinmetz, Thomas, Weintraub, and Kruh are conspicuous in the development of the mercury vapor lamp which, owing to the uniform distribution of its light and the absence of sharply defined shadows, renders it admirably adapted for use in machine shops, drafting rooms, and like places, in which it has found extensive use. The mercury vapor lamp, suitably modified, is also used as a rectifier of alternating currents, especially in the charging of storage batteries from an alternating current source of supply, since it occupies little space and is inexpensive and simple in operation.

Further enumeration might be continued almost indefinitely, but the few instances selected will indicate to how great an extent the development of the arts is due to the inventor whose invention is often not associated with his name.

The First Trans-continental Aeroplane Flight

Account of the Record-breaking Aerial Journey by Calbraith P. Rodgers on a Wright Biplane

BY his arrival at Pasadena, Cal., at 4.04 P. M. on the afternoon of November 5th, aviator Rodgers practically completed his great trans-continental flight, although the real finish did not occur until several days later, when he flew the 35 miles remaining, and landed on the shore of the Pacific Ocean. Rodgers' start was made from the Sheepshead Bay race track, near Coney Island, on September 17th last. He started with the intention of competing for the $50,000 prize offered by the proprietor of a New York newspaper. The time limit within which this prize could be won expired on October 10th, but Rodgers flew on just the same, despite many mishaps and breakdowns. His total time to Pasadena was 49 days. The distance covered was some 3,350 miles, and the time in the air 82 hours. This corresponds to an average speed of about 40 miles an hour.

Besides breaking all records aviator Rodgers carried with him letters from Postmaster-General Hitchcock. Several of these were delivered in Chicago and others, including one from Major-General Grant to the Department of the Pacific and another from the commanding officer of the Atlantic fleet to Rear Admiral Thomas of the Pacific squadron were carried the entire distance across the continent and delivered.

We have followed the progress made by Rodgers from week to week in the columns of the SCIENTIFIC AMERICAN, and now that he has completed his flight, it will be interesting to summarize briefly and give the causes of his various delays. The two chief causes appear to have arisen from bad weather and breakdowns of the motor. He was forced to descend some eight or ten times on account of engine failures. Some of these were simple troubles, such as a wire coming loose or the fouling of a spark plug, but toward the end of his flight, at Imperial Junction, Cal., a connecting rod broke loose and punched a hole in the motor case, and Rodgers was obliged to replace the motor with a spare one which his special train carried. While starting from Middletown N. Y. the second day, Rodgers struck a tree and smashed his machine. This delayed him three days before he could start again. At Shamokin, N. Y., his next stopping place, he descended on account of slight engine trouble and was delayed half a day because of a storm. After flying 50 miles farther to Canisteo, he again descended on account of engine trouble. He mistook a marsh for a solid field and damaged his machine in alighting. The next day, however, he flew 99 miles to Red House, where he alighted to change a spark plug. In restarting, he ran into a wire fence smashing his machine and propellers, which caused a two days' delay. Engine trouble is of course blamed for this, as if he had not alighted at Red House, he would not have collided with the fence there. At one other point in Texas, in starting on a narrow road, Rodgers smashed his machine by colliding with a fence. Two days were spent resting and overhauling the machine at San Antonio and El Paso, Tex., respectively.

All told, some 13¼ days were lost making repairs, and of these, 2½ days can be laid directly to engine trouble. The weather was responsible for the loss of 11 days, so that a total delay of 24½ days was occasioned from weather and repairs. Deducting this from the total time of 49 days, we have 14½ days as the actual time of making the flight, which shows the possibility of crossing the continent in a month's time by aeroplane, in case one does not meet with bad weather and serious mishaps. It should be remembered that Rodgers chose a roundabout way, going far south into Texas and then following the line of the Southern Pacific Railway. He broke the world's long-distance cross-country record on October 10th, when he reached Marshall, Mo., after a flight of 214 miles, as he beat by a few miles Atwood's record of 1,365 from St. Louis to New York, which flight was completed on August 25th.

One of the important events in the course of his flight was his meeting with Robert G. Fowler at Tucson, Ariz. Fowler, it will be remembered, previously tried to cross the Rockies in his Wright biplane, but failed. On October 20th he left Los Angeles, determined to make the flight across the continent by the southern route. Up to November 6th, he had covered 235 miles in 16 days' time.

A comparison of Rodgers' flight with the first trans-continental automobile trip is interesting. The first attempt was made by Alexander Winton and Charles Shanks in 1901, but the Winton car was stuck in the sands of the great American desert. Two years later, however, Dr. H. Nelson Jackson and S. W. Crocker accomplished the feat of crossing from San Francisco to New York in a Winton machine, having a double-opposed-cylinder engine, in 65 days. A single-cylinder Packard automobile, driven by Tom Fetch, accomplished the journey in 62 days, including a four day stop at Denver, and an Oldsmobile, driven by L. L. Whitman, made the journey in 72 days. All three trips were made in the summer of 1903. The following year, Whitman and Carris crossed the continent from the Pacific to the Atlantic, a distance of 4,500 miles, in 33 days, thereby beating by 28 days the best previous record, and in 1906 a 6-cylinder 30-horse-power Franklin air-cooled automobile was driven 4,000 miles across the continent in 15 days, 2 hours, and 12 minutes. This cutting down of the time to one-quarter in but three years shows the rapid development of the automobile from 1903 to 1906.

The aeroplane has developed so much more rapidly that two years ago the past summer, Oliesslagers remained aloft more than five hours and covered a distance of 240 miles, while of late distances of between 700 and 800 miles have been covered in a day with only a few stops. With a reliable motor, and the development of an automatic stability device which will enable the aviator to fly in windy weather it should be possible to cross the continent in ten days' time, and without doubt this will soon be done. What a great time saver the aeroplane is was demonstrated time and again, especially in the far west, where Rodgers frequently out-distanced his special train by from one to two hours. Flying over mountains and canyons he found rather risky, but at the end of his journey he announced that Beachy's flight above Niagara Falls and down the gorge last summer was, in his opinion, the greatest flight ever made. The Wright biplane had for the second time broken the cross-country touring record.

Big Fortunes in Little Inventions

Men Who Saw the Importance of the Apparently Unimportant

By William Atherton Du Puy

EVERY time anybody in the United States pulls the cap off a beer bottle or a soda water bottle with the intent to quench a thirst, temperately or otherwise, he puts the fraction of a cent into the pocket of one William H Painter, of Baltimore A good many people have pulled these caps in the last few years and Painter is consequently an ever increasing millionaire Yet the cap for bottles is a small thing, an idea crystallized and patented The patent is the source of the millions

Painter, however, carried his patent in his pocket for six years before he succeeded in interesting capital in its manufacture Then a man of means advanced the necessary capital in return for a half interest in the patent and a company was formed At the end of the first year he and Painter each had a net $27,000 in his pocket Now the invention has crowded all other stoppers for fizzy water off the market and a big factory in Baltimore turns out the caps by the million every day

Before the time of Painter there was a man by the name of De Quillfeldt who lived in New Jersey and who invented a stopper that took the trade away from the corks of our youth This stopper was of rubber and was tightened by a wire attachment which was pulled down as a lever on the outside of the bottle A decade ago they were generally used on milk bottles De Quillfeldt is said to have made $15,000,000 out of his patent He might have amassed a competence had it not been for William Painter and another equally clever person who fitted a piece of pasteboard into the neck of a milk bottle and took the business away from him

An idea that is perhaps simpler than the pasteboard stopper is the "bump" on the hooks that furnish so much employment for married men just before theater time Women had been fastening their dresses up with hooks and eyes for a generation and it is probable that some one had made a lot of money out of the original invention But hooks had a way of coming unfastened much to the chagrin of the neat and fussy Then came the genius of the hook and eye A man who was wide awake despite his residence in Philadelphia, bent one of these hooks so as to make a bump in it He tried hooking it, and found that it remained hooked He patented it and has monopolized the business through his "see that bump" advertisements ever since

One day a man stood behind his wife while she put up her hair The hairpins of those days were straight pieces of wire They did not "stay put" very effectually The woman in this case bent her hairpins before putting them in Her husband saw her do it The result was the invention of the crinkly hairpin which is to day used in carload lots by the women of the world

So important an invention as the telephone was made by turning a screw one fourth of one revolution All the millions that have resulted from the invention of the Bell telephone, depended upon this slight twist of the wrist of Dr Alexander Graham Bell There had been men before Dr Bell who had come near finding a way to make female gossip and masculine commercial intercourse easier The Reis patents came nearest success But in the Reis patents the current was intermittent It had to leap a gap Dr Bell closed that gap when he turned the screw But Dr Bell was not trying to invent a telephone when he incidentally stumbled upon his secret He was working on a method of making speech visible, for his wife was deaf and dumb and he was seeking an easy method of conversing with her Instead he found the method of talking over a wire to people at a distance He did not patent the idea however and it knocked about his house for months Finally he demonstrated it to some friends and they saw the possibility of its application Upon their advice he patented the invention His patent was filed at ten o'clock in the morning and at three in the afternoon another man applied for a patent on the same thing and lost a hundred million dollars by a nose

Such are the stories that the veterans of the Patent Office gossip about in the moments of their leisure They tell you, for instance of the Selden clutch which is one of the vital patents that has much to do with the control of the automobile business of the country It is this clutch that enables the operator of the machine to stop and start without having to get out and crank his machine—sometimes It is interposed between the running gear and the motor, where it keeps the car marking time while the crossing is blockaded.

This clutch was invented before automobiles were. For a decade after its invention there was no opportunity of applying it to any good purpose Then the automobile was invented In fact George B. Selden was one of the early builders of automobiles and it is logical to suppose that he built them that he might make an opportunity to use his clutch Certain it is that he long had a clutch on the automobile business Before his patent was declared invalid about $2,000,000 had been paid by nearly ninety automobile makers, who found it cheaper to pay than to engage in expensive litigation

Thaddeus Fairbanks was a New England farmer with long whiskers and much Yankee ingenuity In his time old-fashioned steelyards were the only accurate means of weighing the produce of the farm. Platform scales were unknown, for nobody had ever worked out a method of arranging the levers that supported the platform in such a way that an object would pull equally no matter upon what part of the platform it rested Old Thaddeus Fairbanks used to tell the story of the evolution of the arrangement of these levers For a long time the problem was upon his mind He used to lie awake nights and attempt to arrange those levers It was in the dead of night that his thinking finally bore fruit The arrangement unfolded itself and the Fairbanks scale was the result So did a farmer practically monopolize the scale business of the world and so did he write his name upon platform scales wherever civilized man buys and sells by weight

It was a man by the name of Hyman L. Lipman, likewise a resident of Philadelphia, who invented the rubber eraser that throughout our generation has been attached to the lead pencils in common use. It was in 1858 that the invention was made In those times people talked in much smaller figures than nowadays Lipman was, however, able to cash in his patents for a cold hundred thousand dollars when dollars went much farther than they do to-day.

So did a man by the name of Heaton, resident of Providence, notice that mother was occasioned a great deal of trouble because the buttons constantly came off the children's shoes. Heaton devised the little metal staple that holds on the shoe buttons of to-day and realized a fortune for his pains No less clever was a man of the name of Dennison who pasted little rings about the hole in a shipping tag and thus made an "eye" that would not pull out

Elias Howe conceived the idea of placing a hole near the point of a needle and under the encouragement of this small thought was the sewing machine developed Howe was one of the Columbuses in the development of a machine to sew seams and deserves a monument from the women he emancipated from needle work When he asked Congress to extend the term of his patent for a short time (one extension had already been granted he admitted that he had collected $1,185,000 in royalties, but considered himself entitled to $150,000,000.

Howe had many followers who improved the sewing machine One of the cleverest of these was the man who patented the stitch his machine made instead of the machine itself, and thus made infringements more difficult Another man, Allan B Wilson, a journeyman cabinet maker of Pittsfield, Mass, who dropped into the office of the SCIENTIFIC AMERICAN in 1849, exhibited the first model of what has since become known as the four-motion feed He afterward founded the firm of Wheeler & Wilson and became immensely wealthy In the SCIENTIFIC AMERICAN of 1849 James C A Gibbs saw a picture of Wilson's machine. The working of the device was clear down to the point where the needle perforated the cloth He wondered what happened after that. Finally he decided to make the needle work After much thinking and infinite whittling he worked out the ingenious little revolving hook which became the important feature of the Willcox & Gibbs machine and which made that firm wealthy

The man who was born too early to wear, as a boy, red top boots with a brass tip across the toe, was also born too early to feel the true thing in the way of pride run rampant. Silverthorn brass tips, they were called, and they were most serviceable in preventing holes in the toe Silverthorn made his fortune out of them.

There is a palatial mansion up the Hudson with a private yacht moored beneath the Palisades that is a monument to the millions that Adams made in the chewing-gum business. It was in 1871 that chewing gum was patented and millions of willing jaws have wagged industriously upon it ever since.

Harry Hardwick invented an ingrain carpet with the threads of it so interwoven as to prevent wrinkling, and Hardwick is now $4,000,000 better off for his pains.

A towel manufacturer found that his machinery was not working right and that his towels were suffering a vast tangling of the threads. While adjusting the machine he used one of the damaged towels to dry his hands. He found it pleasingly absorbent, and from the idea to which that gave rise was born the bath towel and a fortune to the patentee.

Charles Edward McCarthy was a blind man and lived in South Carolina. He devised a method of attaching mule power to a cotton gin and lived his life out in luxury and ease while the mules did the work.

The cast iron tombstone is a patented article that is to-day covering the graves of many of the dead and departed. It is effective and economical. It has amassed a fortune for its inventor and proven a solace to the mourning yet undecided survivors of the nation's dead.

R. R. Catlin of Washington invented a pattern cat that need but be stuffed with hay and sewed up to become a toy Such figures as "Billikens" and such games as "Pigs in Clover" are always a fortune to the inventor if they become popular. The rubber return ball made much money both for the inventor and likewise for an infringing manufacturer who fought him in the courts.

The brass paper fastener which is still generally used for thick documents, was patented in 1867 by a government clerk by the name of G. W. McGill. Yet it was not new, for the Romans used a similar device two thousand years ago and the modern appliance was but a resurrection.

The patent for a typewriter lay dormant for half a century in France before it ever came into use. Then a man by the name of Sholes made a machine in this country and called it Remington. Another man named Brown made a different kind of typewriter and called it the Smith The patentees immortalized other men by their work They made millions and also made it much more pleasant for the editor who has to read copy

The man who invented tin cans made it necessary for somebody to invent an opener This was done and the money corralled A can opener is not a very laborious thing in the using, but the public is always ready to pay for things that are made easier So, just recently, an inventive genius made a can with a seam just below the top and when the owner wants it open he has but to strike it a blow where the seam breaks and the top is off A single Chicago packer ordered ten millions of these cans as an experiment and others followed suit The inventor has a fortune, and the thing is but just begun

So does the story of the making of big fortunes out of patents on very small and apparently unimportant things pyramid as one goes into the subject. There is a current belief to the effect that but few of the many patents issued are of any practical value The writer had occasion recently to look through a series of the issues of the Patent Office *Gazette* and was struck with the number of patents and found that one in three was assigned, this meaning that a third of all patents issued were sold before completed. These patents must be of value or they would not sell. There are others, of course, that are of value that are retained by the patentee. So it would, on this basis, seem reasonable to estimate that half the patents being issued are of value. Many of them are of stupendous value. An estimate of the revenue being to-day received from patents of the United States would be impossible to make but it seems safe to say that many of the great staple crops will have to look to their honors if a census of patent profits is ever taken.

Silk Growing in the Philippines

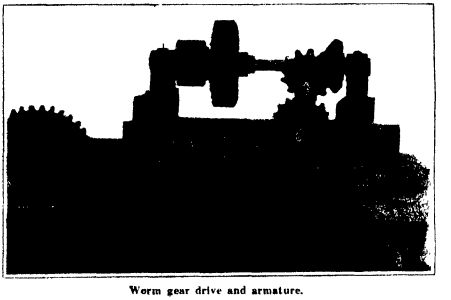
THE Philippine Bureau of Science is making a determined effort to introduce the growing of silk in the Philippines, not only for the purpose of increasing the productive possibilities of the Islands generally, but also as a means of furnishing silk for use in connection with industries already established. Thus considerable silk is used in the weaving of various forms of the well-known "jusi," or pineapple-fiber cloth, for which the Philippines are famous, and ninety-five per cent of this silk is now imported from China.

The trailer now rotting away at Menlo Park.

Edison's Pioneer Electric Railway Work

By T. Commerford Martin

Ruins of one of the trucks.



MENLO PARK, New Jersey, is associated in the popular mind, more perhaps with the incandescent lamp than any other invention, but there also Edison did his great and original work on the telephone, the phonograph, and the electric railway—not to mention a few other things of importance. There does, however, seem to be a general tendency to insist that a man shall have no right to more than one invention, as a basis for fame, just as monogamy is a basis for offspring. Morse for the telegraph, Brush for the arc lamp, Edison for the incandescent lamp, Bell for the telephone, Sprague for the electric railway, Stanley for the transformer, Tesla for modern power transmission, Thomson for electric welding, Marconi for the wireless, Weston for meters—that is about the way the territory of electrical invention is supposed to be roughly divided up. Yet most of these men have done more than one big thing; and in each of the domains there have been other notable figures.

Looking back these thirty years, one might perhaps wonder what Edison was doing with the electric railway in 1880, when he had already so many other inventive troubles on his hands; but no kind of preoccupation ever prevented Edison from taking up a novel idea that challenged his insatiable curiosity and his passion for experiment. Besides, the air was full of a trusting belief that to electricity all things were possible. The successful introduction in quick succession of the quadruplex, the telephone, the dynamo, and both forms of the electric light, was an immense stimulus to other endeavor, and the problem of perfecting and utilizing the electric motor haunted every aspiring imagination. Edison's ambition would have required a straight jacket to keep it away from such an opportunity.

In these days, when long stretches of main railroad are electrified and when every large steam terminal is under sentence of death, as obsolete, it is hard to believe that the beginnings were so crude as the pictures herewith show them to have been. But it had been very much that way for fifty years prior, back to the work of Davenport and Davidson; and one may feel amazed that although so much had been done it all amounted to so little. Evidently a new point of departure had been reached with new men, from whom both in Europe and America real progress must date.

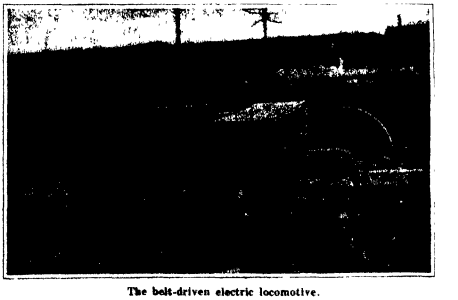
Edison had plenty of spare land around him at Menlo Park, and the adjacent country was not preoccupied by intensive cultivation. Hence it was easy and inexpensive to lay out a single track about one-third of a mile in length which ran from the laboratory along a country road, flanked a hill and came back like a belt to its buckle. The rails were "second" street car rails, and anybody who remembers the street railway construction of the early eighties will not contradict the assertion that the "irons" could not have been much worse. The gage of the track was about three feet six inches, laid with ordinary sleepers on the natural grade. To these sleepers the rails, insulated with tar canvas paper and other stuff not much more effective, were spiked. There were various sharp curves of dangerous short radius, and the hill gave the chance for a nice grade of about 60 feet in 300. It was all delightfully amateurish, but enthusiasm and serious intent carried through.

The power plant consisted of two of the small light-

Worm gear drive and armature.

ing dynamos then being built at the laboratory, each of about 12-horse-power, and the electrical energy was conveyed from them to the track by underground conductors, for which Edison always had a keen predilection as against overhead wires. About 75 amperes at 110 volts was the yield of each machine, so that subject to track losses, not to exceed 25 horse-power, was available at the motor. As with his lighting Edison's traction system was operated in parallel.

The locomotive was worthy the rest of the equipment. It was a four-wheeled iron truck, an ordinary flat dump car, some six feet long and four feet wide. On this chassis, another of the "Z" dynamos of 12-horse-power was mounted as a motor, laid on its side. The armature end projected in front of the locomotive and the rotative movement was transmitted to the driving axle by means of friction pulleys. The wheels of the locomotive had metal rims and a central web of papier maché or wood. The current was taken up from the track on one side by contact brushes, from the wheels, through a brass hub to the motor, and the return circuit was completed through the other set of wheels, i. e., the motor was in parallel. It had its field magnet circuit in permanent connection as a shunt across the rails, with a safety fuse in the shape of a bit of bare copper wire, while a switch in the armature circuit gave the motorman ability to reverse the current flow in the armature and thus reverse the direction of the locomotive.



As one might expect now, though it was not so obvious then, this friction gear was not able to stand up under the strain put upon it, especially when all the "boys" in the shops piled on like rush hour passengers in the subway. May 13th was the day in 1880 when the road was thus tried out, and it was a memorable date at the "Lab," as well as in the history of electric traction, for Edison was thus applying many of the principles of the multiple arc distribution now universal, as well as the low internal resistance dynamo with its high resistance field.

For mechanical transmission, Edison next resorted to belts, and the armature pulley was belted to a countershaft on the locomotive frame, while the countershaft was belted to a pulley on the car axle, and there was an idler pulley for tightening the axle belt, worked by the lever which had previously thrown the friction gear into adjustment. As the motor was started the armature came up to full revolution, the belt was tightened on the car axle and the locomotive moved off. But there was a lot of slip, the rubbing of the belts caused serious charring, and it on the other hand the belt was suddenly tautened up, the armature was burned. The odor of burnt armature was grimly familiar during the tests. The next step in the evolution was to employ a series of resistance boxes in the armature circuit. The locomotive would be started with all of these "cut in," and then it was brought up to full speed by cutting them out successively. After loading up the locomotive with a generous superabundance of these boxes, Edison came to the conclusion that he was carrying a lot of unnecessary dead weight. He, therefore, dispensed with most of them very ingeniously by winding copper resistance wire around one of the long legs of the motor field magnet. There it occupied no space, was inconspicuous, served as an additional field coil in starting up the motor, and proved an important advance. This coil was also in

The electric train of Menlo Park.

The belt-driven electric locomotive.

EDISON'S PIONEER ELECTRIC RAILWAY WORK

Perpetual Motion

Some Examples of Misguided Ingenuity

OUT of nothing, nothing comes. This is really a wonderful axiom. Men will grant it at once as an abstract proposition. But when they apply it to real things, some seem to get confused, and entertain expectations which if realized would set this axiom at naught. The same general truth is expressed by the statement, *Every effect must have a cause.* This, too, will be granted by pretty much everybody, until application to real things is made.

Perhaps no one has trouble with a case where there is absolutely nothing at all. From a space where there is no matter, whether solid, liquid or gaseous, no one will expect anything. But juggle matters a little. Put in *A*, put in *B*. Suppose it to be known just what *A* will accomplish and what *B*. And suppose, further, that we have found, subsequent to our combination of *A* and *B*, that we can trace these accomplishments of *A* and *B*. Call them *a* and *b*. Now right here is where some seem to go astray. They seem willing to believe that in addition a new thing, *c*, might *somehow* turn up. Well, if it should, then we will have a case of something coming from nothing. We might, just as well, expect that sometimes 2 and 2 would produce 5. The additional unit here would be no more wonderful than *c*.

This is the trouble with the seekers after perpetual motion. They really expect something from nothing, they expect an effect without a cause to produce it. They take a machine (*A*) and a certain amount of energy (*B*) and expect that somehow the combination will give rise not merely to the machine itself (*a*) and a total of energy (*b*) equivalent in amount to what they put in (*B*). They expect not merely *a* and *b*; they look for an additional energy *c*. If they get it, they will get something out of nothing; they will get an effect without a cause behind it. It is just as ridiculous as expecting to get 17 separate ounces of metal by cutting up a pound of steel. Just as soon as one thoroughly grasps the idea that energy is a real thing, he is prepared to understand that it cannot be increased by manipulating it. He is then ready to see that, if he puts 2 foot-pounds into a machine, he cannot expect to get 2½ foot-pounds out. Indeed, he may apparently get *less* than 2, because some of the energy will be transformed into heat and will be radiated off and thus may escape observation.

However, men have been working at the impossible problem of getting something out of nothing for hundreds of years. And, some are probably still at it. No doubt, there are to-day men in the United States who think that a machine can *somehow* be made, which will run without energy being constantly put into it. It is just as if they expected to cut the 8-inch square into two separate parts, and get a 5 x 13 inch rectangle by putting these parts together in a different way.

That the possibility of a perpetual motion machine has not been entirely given up will be understood when it is learned that 575 application for patents for such apparatus were made to the British Patent Office in the period 1855 to 1903. This is about ten patents a year.

In Fig. 1 we have an example cited by Mr. F. F. Charlesworth of the British Patent Office. An endless band or chain is arranged to mesh with two sprocket wheels. The band carries a series of cups, or rather dippers so attached that the handles are continually perpendicular to the band. Heavy balls are fed one by one to the open dippers on the descending side. When the dipper nears the bottom, a projecting horn intercepts the ball and guides it away. It will be seen that this machine will run as long as the balls are fed in at the top. In the form shown, an elevating screw is used to bring the balls to the top and permit their use over again. This endless screw is driven by mechanism connected with the shaft of the upper sprocket wheel. The thing lost sight of here is the fact that it will require as much energy to lift the ball to its initial position as it will develop by falling. It was proposed, apparently for this same machine, to provide for the return lift of the balls by conducting them along an incline to a hollow tower filled with quicksilver or some other liquid. Once a ball had entered the base of the tower, it would rise to the surface of the quicksilver because of the difference in specific gravity. It could then be recovered by a lifting device, dropped onto an incline and fed into the machine again at the top. A very fine scheme—the only difficulty lay in getting the balls into the bottom of the quicksilver column.

Consider now Fig. 2. We have here a similar arrangement to that shown in Fig. 1. However, the endless band is here of rubber and hollow. Instead of dippers, there are hollow rubber projections or arms. On the following side of each of the arms, conceiving the whole to turn with the hands of a watch are air-sacks. To these weights are attached. When an arm is rising and the weight is consequently underneath, there will be a distension of the sack. This entire apparatus is immersed in water. It is expected that it will now begin to move clockwise. The rising side is lighter than the descending one because the distention of the air-sacks has decreased the specific gravity on the one side. All air compartments communicate with the main tube. There is no change in the tension of the air. As a weight at the top passes into the position where its sack collapses, another sack will be distended at the bottom, and so the air required will have the same volume. At any rate, this is the general scheme. But why won't it work? The reason lies in the progressively increasing pressure of water as one passes downward beneath the surface. It is this that should raise the distended side. But it is also this that resists the movement of air from the top to distend an air-sack at the bottom. The distension of the air-sack at the bottom is broadly the same problem as introducing a metal ball into the bottom of the column of quicksilver.

Refer now to Fig. 3. This represents what appears to have been a French "solution." An air-tight bellows *DFE* is arranged on an axis perpendicular to the paper. The total length of the bellows is about 40 inches. There is an aperture at *E'*, by means of which and a suitable tube there is a communication between the interior of the bellows and a vessel of mercury *G*. This vessel is fixed in position at about the level of the shaft on which the bellows turns. *B* is a counterpoise, while *C* is a clasp which serves to retain the bellows in position with a moderate amount of strength. Suppose now the bellows to be forced open, say, to a third of its capacity. Quicksilver will flow from *G* and after a time, so it is claimed, the weight within the bellows will exert a turning effort sufficient to cause it to break away from the clasp. The lower end of the tube *E* will continue in the mercury bath. Then the entire movement will be arrested at the position shown in Fig. 4, and another clasp *H* will engage the bellows. The mercury rose before, because of the height of the tube *E* being less than that of the usual barometric column. The mercury now will run out from the bellows and the latter will collapse. The counterpoise *B* then operates to bring the bellows back to its initial position. Arrived here, whatever mercury remains within, falls to about 27 inches height, whereupon mercury from the reservoir will rise to flow into the bellows, because the length of the tube *E* is considerably less than 27 inches. This is essentially Dr. Papin's account of this scheme. What is wrong with the device?

Consider now Fig. 5. Here we have a drum filled with water or other liquid and arranged on trunnions. Upon one of the trunnions, a fly wheel is mounted and a suitable belt carries the power from the generator of perpetual motion. By means of stuffing boxes two rods pass through the drum. These rods are mutually perpendicular. Weights are arranged on the ends of these. It will be understood that if we could always have the same amount of weight on the two sides of a drum or wheel, but the weight on one side so managed as to be further from the axis of rotation, the wheel or drum would turn. The excess of leverage on one side would cause that side continually to descend. To manage this shifting of the weights, the inventor provided the rods with cork spheres centrally arranged. Evidently when the one rod is vertical, its cork float will, if suitably dimensioned with respect to the two weights, cause the upper weight to rise and so project from the drum at a maximum distance. There will be no tendency for this position to be lost until after this vertical rod has taken up a horizontal position. The condition shown in the figures is where one rod is vertical and the other horizontal. The vertical rod and its weights will, apart from previous movement, exert no turning effort. But the horizontal one will, since one of its weights is farther from the axis than the other. Motion will be set up in the direction of the arrow. Of course the rods must be so arranged as to prevent interference between their cork floats.

A simple device is shown in Fig. 6. An endless chain passes around two wheels *BB*. A trio of idle wheels *CCD* deflects the chain from the vertical on one side. The result here is that a greater length and consequently a greater weight of chain are continually on the right-hand side. Presumably, we have a clockwise movement here. The difficulty is that the deflected portion, although heavier, does not exert the full effect of its weight. The gravitative pull of this portion operates downwardly in an exactly vertical direction. But since this gravitative motion is nonuseful, as we say, on the topmost wheel, at an angle, there is some loss. To make this perfectly clear, suppose a chain to hang precisely vertical. At the point of tangency the gravitative pull will be in the direction of the tangent and therefore most effective. Deflect the chain in or out, and the gravitative pull will be at an angle to the tangent and so at some loss. In point of fact the axles of the wheels *BCB* sustain a certain fraction of the weight of the chain.

Consider Fig. 7. Three rotatable shafts are arranged horizontally so that a vertical section would show the shaft sections at the vertices of a right-angled triangle, as disclosed in the figure. Suppose now that an endless chain be arranged to envelop these rollers. It might be thought that, since the hypothenuse is longer than the vertical side, a uniform chain would set up a clockwise movement. The explanation just given, however, prepares us to understand that this will not be the case. In fact the disadvantage under which the gravitative pull of the hypothenuse is delivered is just compensated by its excess of weight. Such an arrangement will be a well-balanced, immovable one. But suppose that the metal chain be replaced by a band to which sponges are attached, the whole being enveloped by a string of evenly distributed weights. Suppose, in addition, that the horizontal portion of the apparatus be immersed in water. We now have a device conceived by Sir William Congreve, probably about 1827. Sir William was a member of the British Parliament and the inventor of the celebrated Congreve rockets. This machine was expected to turn counter-clockwise. The *modus operandi* was conceived to be as follows: On the vertical side a sponge as it entered the water would be uncompressed by the string of weights and therefore free to absorb water by capillary attraction. As a sponge emerged from the water at the lower end of the hypothenuse, the line of weights would operate to compress it and thus keep it comparatively dry. Because of the difference in weight on the dry and wet sides, the whole system would move.

Perhaps the most celebrated efforts in the direction of perpetual motion have been made in connection with the continued distribution and redistribution of weights within or about a wheel movably mounted upon an axle or trunnions. The purpose is to have the same number of weights upon the downgoing and upgoing sides, but to have the average distance from the axis of rotation greater upon the downgoing side. It is conceived that, on the principle of a difference in leverage exerted by the two groups of weights, we should get a never-ceasing motion, if this relation could be perpetually maintained. One of the most distinguished of those who gave attention to this matter was the second Marquis of Worcester who flourished about the middle of the seventeenth century. This gentleman wrote in his "Century of Inventions" of a device whose purpose was "to provide and make that all ye weights of ye da/cending syde of a wheele shal be perpetually further from ye center, then tho/e of ye mounting syde, and yett equall in number and heft on ye one syde as ye other. A moſt incredible thing if not scene, butt tryed before ye late King of happy and glorious memorye in ye Towre by my directions, two Extraordinary Emba/adors accompanying his Maſte and ye D. of Richmond, D. Hamilton, and moſt part of ye Court attending him."

He goes on to relate that the wheel, or drum, was 14 feet in diameter and was provided with 40 weights of 50 pounds each. When this wheel was put in motion, it was claimed, so it seems, that as the weights successively passed the vertical diameter above they hung a foot further from the center, and that as they passed this diameter on the lower side they would hang a foot nearer. It would seem that the precise method by which this result was accomplished is not certainly known. However, it is thought to be substantially as indicated in Fig. 8. It will be seen that the distribution to right and left is about equal, so that so far as more weight is concerned, we have a balance. But there is a preponderance of leverage on one side. The view represents the position at a certain definite instant. And we may grant that this instant displays conditions in a fairly typical manner. It would seem then that the Marquis was perhaps gratified when he said, "See pleated to judge ye consequence."

Half a century or thereabouts later, a celebrated apparatus was constructed more than once by Jean

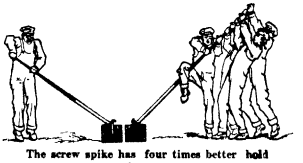
SOME EXAMPLES OF MISGUIDED INGENUITY

A gang at work with the self-propelled spiking truck.

Spike Driving by Motor Truck



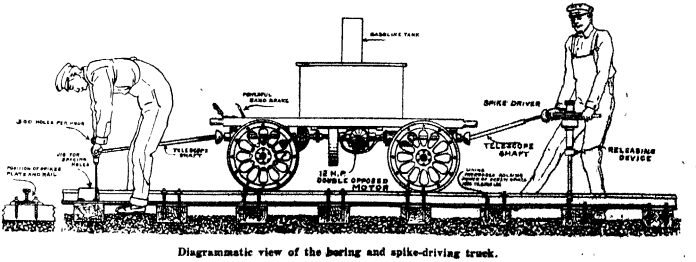
Protecting the Public from Railway Accidents

THE number of ties required annually for renewals and new track by the railroads of the United States is estimated at 154,000,000, which, at an average cost of 50 cents apiece, represents the enormous sum of $77,000,000. Less than half of these, an ever lessening supply, are hardwood. Soft wood ties become unfit for service from decay, chiefly of the fibers under the rail, where the wood is cut and injured by the rough nail spikes with the continual up and down play of the rail and spike. When we remember that any loosening of the spikes, with consequent spreading of the rails, is liable to lead to most serious accidents and loss of life, the importance of the problem of thoroughly securing the rails to the ties becomes obvious.

Screw spikes have been introduced with much advantage in place of nail spikes. In the first place, the screw, in entering the wood, does not injure it to the same extent as the nail spike; secondly, an item of no small importance, a screw spike has about four times the holding power of a nail spike, as indicated diagrammatically in one of our illustrations. This greatly lessens rail movement with the resultant loosening of the spike and laying open of a cavity in the wood into which rain and moisture penetrate.

One of the principal obstacles which have hitherto stood in the way of general adoption of screw spikes in this country has been the expense of putting them in by hand labor and with primitive tools. But this obstacle is one which can be and has been removed. Our half-tone illustration and one of the line drawings illustrate a self-propelled gasoline motor car which is in service boring ties and inserting screw spikes by mechanical power. This not only reduces the cost of spiking to a minimum, but also greatly expedites the operation of track laying and re-spiking.

The motor car is provided with cranes at the drilling end which hold the drills when not in operation. At the spike driving end similar cranes are provided, which hold up the spike drivers at all times. These cranes not only take up the whole of the weight of the instrument but also the torsional thrust, so that the operator is merely required to exert a downward pressure on the tool, to keep the spike driver from slipping off the head of the spike, and to move the driver from one spike to another. The spherical bulb near the bottom of the instrument, seen on the right-hand side of the line drawing, is a friction clutch adjusted to slip when the spike has been screwed in to the desired degree of firmness. Without this friction clutch the engine would be stalled or the head of the spike twisted off. The spike driver is connected to the motor by a telescoping shaft of such length that three ties can be reached without moving the car. The work of boring the holes is effected ten times more rapidly with this equipment than by hand, and requires less skill, and



The screw spike has four times better hold than the nail spike.

of course much less effort. The cost of labor also is greatly reduced. The car is kept on the track throughout and is advanced just as fast as the spikes are screwed into place. When not in use the drill and extension shaft are hung in the hook of the crane. The modern standard track laid with this gasoline motor car consists of 110 pound rails, carried on tie plates and fastened by means of screw spikes to treated ties. The gasoline engine is sufficiently powerful to haul when necessary two or three cars loaded with section men and their supplies, such as jacks, claw bars, lining bars, shovels, ties and rails. A specially designed friction clutch in the connection between the engine and the propelling gear of the car makes it possible to start a heavy load from a standstill without stalling the engine. The clutch may, of course, be thrown out entirely when the car is standing still and the engine is being used for spike driving. There is no doubt that the car will find many other applications beside that for which it is specifically designed. If run in conjunction with a small auxiliary air compressor or electric generator, it will be handy for operating rivetting hammers or similar tools at a distance. It might be used for spraying paint or mixing concrete. By adding a suitable blade attachment the car may be turned into a mowing machine for cutting grass and weeds from the right of way, or it may be used to operate mechanical tamping bars which are being developed in connection with this outfit.

One of the valuable features of the car is its great simplicity. A lever in the hands of the operator controls the motion forward or backward. The throttle and spark control levers are on the seat just behind the operator's right knee, while a lever under his foot operates the brake. At the back of the seat is a gasoline supply tank which holds a sufficient quantity of the oil for ten hours' continuous operation.

The motor is arranged crosswise, a position which is said to provide a maximum cooling effect during motion. The car has started without difficulty on a heavy grade and a 23 degree curve with all the men on board who could get a foothold.

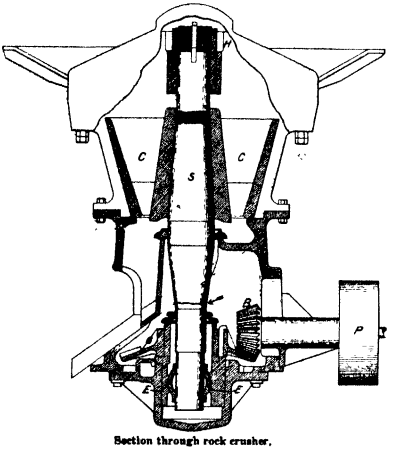
Diagrammatic view of the boring and spike-driving truck.

SPIKE DRIVING BY MOTOR TRUCK

The Kubus of Sumatra

PROF. W. VOLZ, of Breslau University, has published in *Petermanns Mitteilungen* a paper on the Kubus, who live in the interior forests of Sumatra, and, owing to their complete isolation by several natural barriers, appear to be a typical example of an absolutely primitive race. The life of the Kubus is comparable to that of the anthropoid apes (gibbons), which inhabit the same forests; they appear to be at the lowest stage of economic development—the gathering stage—having not yet become hunters. Prof. Volz believes that they totally lack religious conceptions.

Welding a Fourteen-inch Shaft by the Thermite Process



A Fine Example of the Adaptability of Dr. Goldschmidt's Method

THE Goldschmidt thermite process has now become so firmly established in various industries, that we accept it more or less as a matter of course, and have almost ceased to be stirred by the spectacular liberation of energy which accompanies its application to various purposes of ordinary industrial use. When, however, such a gigantic operation as the welding of a fourteen-inch shaft is in progress, even the most cold-blooded witness must wonder at the fierce intensity of the reaction and at the perfect control under which it is kept. Most violent reactions are explosive in character, owing to the disengagement of large volumes of heated gas. The thermite reaction has the great advantage that all substances taking part therein, both the initial material and the products, are solid.

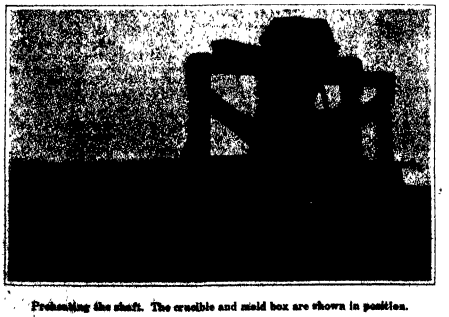
A rock crusher belonging to the North River Stone Company, Kingston, N. Y., was recently disabled by the fracture of the central shaft. The construction and mode of working of this crusher can be gathered from the accompanying illustration. A vertical shaft *S* is suspended from a head *H*, and extends axially through the crusher-chamber *C*, the walls of which are faced with a lining *L*. A similar lining *L'* is placed around the working face of the conical portion of the shaft. The latter, at its lower extremity, is held in an eccentric bearing *E*, which is rotated in the casing of the crusher by the gear *G* through the beveled pinion *B* and pulley *P*. The motion of the shaft is that of a conical pendulum, that is to say, its upper extremity is fixed, while the lower end travels around in a circle. There is no rotation about the axis of the shaft. The rock is fed into the crusher-chamber, and is there ground between the lining of the hopper-walls and the sleeve of the shaft, as the latter revolves in its eccentric orbit, thus periodically approaching toward and receding from a given point of the chamber wall. The ground rock issues at the side by a chute. The break occurred near the point where the lower cylindrical portion of the shaft joins the tapering conical part. (The location of the fracture is indicated in the drawing by an arrow.) The shaft here measures 14 inches in diameter, while at its thickest part it is 22 inches across. The total length is 18 feet, and the weight about seven tons.

The accident to the shaft meant a period of idleness of at the very least six or eight weeks if a new shaft were ordered. The owners of the plant therefore turned their thoughts to the possibilities of repairing the damage by the aid of the Goldschmidt process. This plan was ultimately realized with a saving of several weeks' time and at about one-third the cost of a new shaft. The broken member was shipped to the works of the Goldschmidt Thermite Company, at Jersey City. The fractured surface was pared off with the oxygen blast, taking away in all about 2¼ inches. The two portions of the shaft were then mounted upon a solid concrete bed, so as to secure perfect alinement, with the space of about two and one-half inches left open between the two ends that were to be welded.

The first step toward effecting the weld is to prepare the mold. For this purpose a wax pattern of the finished joint is first formed about the ends to be joined, and the mold, of equal proportions of fire clay, ground fire brick, and fire sand, is then built up around the shaft, leaving of course channels for pouring in the charge, a riser to allow for the contraction of the cooling metal, and a blast hole, for the introduction of a gasoline compressed-air torch, to preheat

Section through rock crusher.
The shaft broke at the point marked by an arrow

the mold and casting before welding. During the actual operation this blast hole is plugged. The mold is enclosed in sheet iron walls, and this completes the welding furnace.



During the preheating, which occupied in this case about ten hours, the wax pattern of course melts away, leaving a free space for the metal of the welded joint. About the furnace is built a wooden scaffolding of trestles, which supports the hoppers containing the charge of thermite, as seen in one of our illustrations. It may seem odd that wood should be used for this structure, since it has to withstand not only the heat of the furnace during the preheating operation, but also the assault of the spattering charge and slag during the reaction. As a matter of fact wood serves its purpose quite satisfactorily, for though it has to be continually watched and kept moistened, and is pretty sure to catch fire during the reaction, it holds up very well even under these strenuous conditions, while an iron structure would be cut right through by any of the molten charge falling upon it. The charge consisted of 1,100 pounds of thermite, mixed with 25 per cent of small steel punchings, 1 per cent of chromium thermite, and 1 per cent pure carbon free manganese. This charge of thermite, exclusive of steel punchings, is about enough to make 600 pounds of steel. The reaction temperature is about 5,400 deg. F.

After adding a teaspoonful of ignition powder (barium peroxide and aluminium flake) to each hopper, the reaction is started by introducing a red hot iron bolt. A flash, a glare, a hiss and sputter, and clouds of smoke envelop all, as the elements wrestle in fierce combat for union with the coveted oxygen, the greater affinity of the aluminium quickly asserts itself, and after a forty seconds' round the iron is vanquished, thrown out of combination and enslaved in the service of man. About one minute is allowed to lapse in order to allow the slag to separate, then the tap-holes of the hoppers are pushed open, and the white-hot molten charge runs into the mold, filling the space prepared for it, and effecting the union of the adjoining ends of the broken shaft. The main part of the work is now done. It only remains to allow the iron to cool—a matter of some forty hours—and the mold can be broken away, exposing the welded joint to view. The excrescences left by the pouring holes and the riser are cut off with the oxygen blast, and the job is completed—for in this particular case there is no need of machining the welded joint.

The repair of the crusher shaft was thus effected with complete success, giving one more striking example of the wonderful possibilities of the Goldschmidt thermite process.

Horse-power and Man-power

IN connection with steamship propulsion the average man is apt to speak very glibly of so many hundred, or thousand, horse-power. But, says the *Railway and Locomotive Engineering*, it is extremely doubtful if one person in a hundred really has a due appreciation of what the phrase actually means. On this point some very interesting remarks were made at the last annual dinner of the Scottish staff of *Lloyd's Register* by Mr. John Heck, the Glasgow engineer surveyor to the society. Proposing the toast of "shipbuilding and engineering," he said that, calculating the strength of twelve men to be equal to one horse power, it would require 840,000 men to produce as much energy as the 70,000 horse-power developed by the turbine machinery of the express Cunarder "Lusitania." Then, if the men were to work on the eight-hour day system those figures would give a total of 2,520,000, that being the number of men whose strength would be necessary to drive the vessel across the Atlantic Ocean. So it would take all the men in Scotland to supply the energy produced all the day round by the wonderful turbine machinery of this great ship.

Preheating the shaft. The crucible and mold box are shown in position.

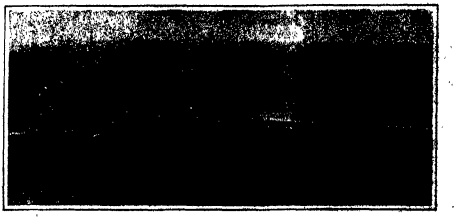
WELDING A FOURTEEN-INCH SHAFT BY THE THERMITE PROCESS.

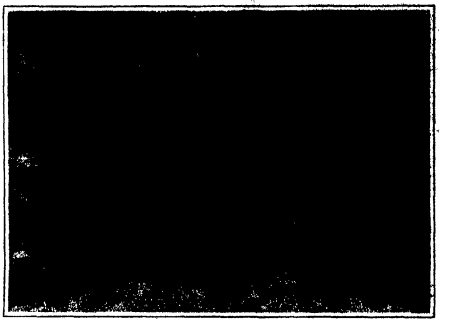


Curiosities of Science and Invention

A Vessel Broken in Two

THE accompanying photograph shows the wreck of the steamship "Santa Rosa" belonging to the Pacific Coast Steamship Company, of San Francisco. For some years past, the "Santa Rosa" has been plying between San Francisco and San Diego, on the coast of Southern California. While on a voyage to the latter port, the vessel veered from her usual course, during heavy weather, and very early on the morning of July 7th, she piled up on the rocks of Point Arguello, near Santa Barbara. At the time, the steamship carried about 200 passengers, and a heavy and valuable cargo.

Four vessels very soon came to the rescue of the "Santa Rosa," and strenuous efforts were made to pull her off of the reef. Hawsers were hitched to the stern of the steamer, and the four vessels began tugging away. A heavy sea was running and the rocks on which the vessel was lodged, were very ragged and sharp. Between the rocks and the angry sea, the "Santa Rosa" broke about amidship but still hung together. However, the enormous strain of the four tugging vessels, was so great, that the steamship was literally pulled in twain—just as she appears in the photograph—making a very odd-looking wreck—one of the most peculiar ever seen on the Pacific Coast.



Both stranded steamer and the cargo proved a total loss.

Broken in two on the edge of a reef.

Devastation upon the Railroad Caused by the Breaking of the Austin Dam

THE accompanying photograph gives an excellent idea of the tremendous power in a stream of water that is suddenly released, as was the case when the dam broke at Austin, Pa. recently. In the path of the onrushing water were located the yards and railway shops. One would scarcely believe that so substantial and heavy a piece of machinery as a freight locomotive could be completely demolished by the water, yet the photograph shows two of these engines almost as badly damaged as they would have been in a collision or by the bursting of their boilers. In the foreground appears the truck of a freight car. The car itself was undoubtedly carried far down stream with the onrushing current. The tracks of the railroad were twisted and bent, in one instance even into a complete circle.

Locomotives wrecked as the result of the breaking of the Austin dam.

An Automobile Scissors Grinder

AN ingenious French mechanic is shown at work in the accompanying illustration, sharpening a pair of shears. With a small gasoline motor three wheels, a pair of springs, etc., he has built himself a novel tricar with which he can quickly go from place to place and drum up trade. A similar vehicle can be seen about the streets of New York, but the American scissors grinder has only progressed to the point of using a gasoline motor to run his grindstone, both the latter and the motor being mounted in a horse-drawn wagon. The Frenchman has the advantage of not having a horse to feed, and as long as he is a mechanic, he has no difficulty in keeping his novel tricar in repair.

A self-propelled scissors grinder.

Veterinary Use of X-Ray Photography

FOR several years Roentgen-rays have been used successfully by the medical profession as a means of determining the nature of a broken bone, thus facilitating the setting of it, and the location of foreign bodies such as bullets in the human body. But, never before to our immediate knowledge has this branch of science been used to aid the veterinarian in the examination of a horse.

Taking an X-ray photograph of a horse's injured leg.

The owner of a stock farm, near Lexington, Kentucky, has a very valuable young horse which was injured about three inches above the pastern on the left hind leg. The surgeon in charge thought that probably a nail or other foreign body was broken off in the injured part. The horse was brought to Prof. M. L. Pence, of the State University of Kansas. Wires from the coil were passed out of the window of the Physics Building and connected to the Roentgen-ray tube which was held in a clamp stand.

The horse's right hind leg was held up as if being shod, while the tube was placed about sixteen inches from the part to be photographed. The sensitized plate was held as near the leg as possible on the opposite side from the tube and the exposure made. Two such exposures of different lengths were made, the one of ten seconds giving excellent results. A Roentgen-ray picture of the hand may be made with this coil by an exposure of two or three seconds. With a coil requiring several minutes to make an exposure, it would in all probability be difficult to get a horse to refrain from moving long enough to obtain the exposure.

The interrupterless coil used is an extraordinarily fine one of German make, this being the first university in the United States to have one of this type. It is admirably suited for many other experiments in the physical laboratory.

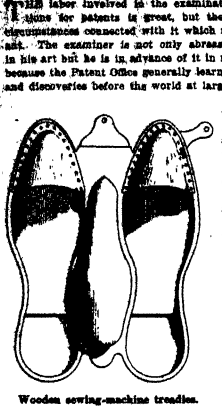
The Exploration of the Brahmaputra

IN his presidential address before the Royal Geographical Society last May, Major Leonard Darwin named three fields in which the explorer may yet hope to win renown by robbing the unknown of its romance—the South Pole, the interior of Arabia, and the bend of the Brahmaputra.

The reasons why the siege of the South Pole has been so painfully protracted are sufficiently obvious; a glance at the map of Arabia shows a blank space of formidable dimensions, which, even if the country were less inhospitable and its inhabitants less hostile, might keep explorers busy for many a year; but the unknown stretch of the Brahmaputra, just north of the British frontier in Tibet, is so insignificant in extent that only the largest-scale maps of the present day distinguish it with dotted lines. The length of this portion, to which no European and no native surveyor under the Indian government has yet been able to gain access, is actually much less than one hundred miles.

Much of the surrounding country has been explored, and the general trend of the land is so well known that the identity of the Brahmaputra of Assam with the Tsangpo of Tibet is absolutely unquestionable. Yet even the attempts to obtain direct evidence of their identity by floating marked logs from the upper river, have hitherto proved unsuccessful.

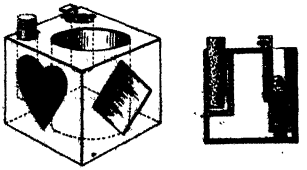
There are two reasons why the many efforts heretofore made to unlock the mystery of the river have failed; first the extraordinary roughness of the country, and second the savage hostility of the Abors, the tribe through whose country the river runs. It is known that there is an enormous difference of level between the two known portions of the river. In a stretch of 130 miles the fall amounts to 10,000 feet; hence the descriptions emanating from Tibetan sources of stupendous gorges, falls, and rapids are quite credible.



The savage character of the Abiyes was manifested a few months ago, when the latest attempt to ascend the river reached in the massacre of Mr. Noel Williamson, assistant political officer at Sadiya, his companion, Dr. Gregorson, and a party of 200 men.

The Funny Side of Invention

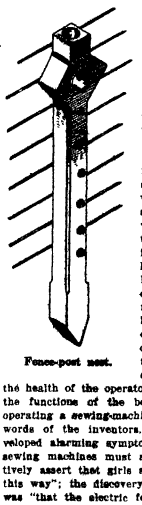
"Patentable Utility" as Illustrated in Some Issued Patents



By Laurence J. Gallagher

THE labor involved in the examination of applications for patents is great, but there are certain circumstances connected with it which render it pleasant. The examiner is not only abreast of the times in his art but he is in advance of it in many instances because the Patent Office generally learns of inventions and discoveries before the world at large. Apart from the consideration of theories which are advanced in support of new inventions, the examiner also has to meet and successfully refute those theories which have no foundation or which are clearly due to the efforts of the applicant to obtain a patent. The patent law requires that an invention have utility and it is in setting forth the utility and in explaining it that many applicants go astray. This is especially true of the applicant who is prosecuting his own case and who, very generally, is ignorant of the technical requirements. Some applicants in the electrical art can see benefits in the use of their device which never occurred to others; they are enthusiastic over their discoveries and their elemental knowledge is supplemented in certain cases by imagination. Many of these applicants believe that the examiner cannot understand their inventions when the utility is questioned by him and the applicant is called upon for further information

Wooden sewing-machine treadles.



One inventor proposed to make a magnetic belt of a number of batteries adapted to encircle the body, the belt also containing a number of permanent magnets placed adjacent to the end cells of the batteries so that "each cell would be a pole"; it was also proposed to provide a vacuum in the belt, "this vacuum or hiatus to be filled with acid." The purpose of the belt was to furnish magnetic currents to the body, "all the electric currents of the batteries being converted into magnetism." The number of cells in each battery could be varied at will since "the greater the number of batteries used the greater would be the magnetism until sufficient batteries were added to produce magnetic stress." The terminals of each battery were to be in contact with the skin, the magnetic currents flowing through the body, the operation being described as follows: "When the belt is applied to the body, magnetism is produced by detached currents of electricity which are alternated and induced through the body according to the laws of inductive diffusion and reflex action. This passing of current through the body in this manner produces a sedative and tonic

The indispensable tally block.

effect; the more the batteries are used the greater will be the magnetic potency and polarity." The particular function of the "vacuum or hiatus filled with acid" was "to break up the currents that would tend to run around the belt, thereby assisting in forming alternating currents, the alternating currents being held in suspension by magnetic force, the crossing of the alternating currents producing minor magnetic centers in the body, the induced currents produced by the magnets damping the alternating currents in producing magneto-electric currents."

The name magnetic belt was objected to by the examiner who suggested that electric belt would be a proper term; the inventor replied to this as follows: "If my magnetic belt makes more magnetism than electricity, then it is a magnetic belt and is rightly named; if four or more of my batteries in my belt do not make an excess of magnetism then it makes nothing; electricity makes magnetism and cannot live without it. Magnetism is a mode of permanent electric force, and it differs from the other modes of electric force in that the energy it excites in a body is always present, especially at the extremities, the extremities of a magnet are called poles, and the properties they exhibit are termed polarity, polarity increases magnetic force; the more poles the more magnetism. When four electric currents are properly arranged in my belt the ceaseless flow of interchangeable inductive alternating currents become supreme in magnetic force and potency. One battery alone in my case makes a direct electric current; but four or a dozen batteries, four or a dozen currents, four or a dozen magnetic fields, detached, having broken currents, and when within an electrical radius of one another, producing induction and an amalgamation of mixed currents which are magnetic by an overcharge of magnetic poles, electric currents, and magnetic fields. An electric current is a stimulant and an exciter and dangerous in cases of fever and heart disease; a magnetic current is sedative and safe in the above cases; this I have experienced in treating patients and this is another reason why my belt is not an electric belt; but a magnetic belt is the same as an electro-magnetic belt, and is better understood; magnetism and electricity go together in some proportion anyway, and magneto-electric would suit no better than my original name of "Magnetic Belt." The inventor probably became muddled as he proceeded in his argument which accounts for the statement that, "magnetism and electricity go together in some proportion anyway."

Fence-post rest.

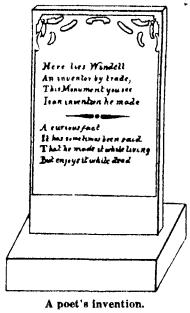
Another invention had for its object the diminishing of sickness and death among women and girls who operate sewing machines. The inventors in this case had spent twenty-five years investigating the physical and mental laws of health-culture and life forces, the causes of diseased humanity, and the remedies, and for ten years had been observing the many evils resulting from operating on sewing machines. During that space of time they did not find one case where the health of the operator remained good, and where the functions of the body were undisturbed after operating a sewing-machine for a short time, in the words of the inventors, "six months generally developed alarming symptoms." While admitting that sewing machines must and will be used, "we positively assert that girls and woman are sacrificed in this way"; the discovery which led to the invention was "that the electric forces of the system, in connection with the iron treadle and steel plate, are the ever-growing source of trouble in operating sewing machines." From many experiments the inventors explained the source of trouble as follows: "It is the electric current created by the friction, and the feet of the operator in contact with the iron treadle, and the hands with the steel plate. The treadle of the old spinning-wheel was wood; consequently there was no waste, and no cold feet. The wooden sandal naturally becomes warm from the system, and it being porous, and an element conducive to nature, it will assist the forces of the body and the friction produced does no harm. We have operated sufficiently to report from experience, and we know it is not the physical force needed to run the machine which leads to the alarming symptoms; neither is it the motion, as the motion under proper conditions would be beneficial. We consider rubber just as objectionable as iron and have seen many cases of disease from rubber coming in contact with the physical system."

The invention consisted in making the sandals which were connected to the treadle of the machine of wood, the feet being positioned in the sandals by means of leather straps, together with a wooden plate on the top of the machine and adjacent the needle and on which the operator's hands would rest while running the machine. This case is a good example of an exception to the rule that mere change of material does not amount to invention, since the humanitarian object of the invention and the untold benefits which would follow its use carried dignity.

Another inventor devised an attachment for telephones and submitted a description which was not clear to the examiner, upon being asked for further description the inventor replied as follows: "This instrument will work the minute central inserts the plug and therefore it enables a person to come to the 'phone before the same rings."

Mirrors in fork and knife handles.

Persons with excessive abdominal weight may reduce the same if they will make use of a device which exhibits much ingenuity in its manner of use, the corpulent one has himself strapped to a frame which extends down his back, there being a handle attached to the frame. He then lies down with his face to the floor and the frame and himself are rocked back and forth, the protruding mass of adipose forming an excellent fulcrum. The production and use of such an invention is a boon to humanity; the person of excessive weight may bring himself to size adapted to fit into the ordinary chair while those about him can use the space to which they feel entitled.



The prevention of collisions between railroad trains has offered and still offers a fruitful field for inventions. Whenever a person of prominence or authority travels over a railroad it is the general practice to have a pilot train precede the one in which he is riding; of course this is a departure from the general run of things and how to accomplish the same degree of safety with less trouble has prompted many ingenious minds. One patentee discloses a novel method, the invention involving the use of a pilot having telescoping members connecting it with the front of the locomotive. In the event of a train coming in the opposite direction on the same track the pilot will collide with the other train or with a similar pilot connected thereto, the result being that the telescoping connecting members slide into each other such movement resulting in closing the throttles and setting the brakes. The utility of the pilot is increased by providing a bell thereon together with an automaton for striking it, while the pilot is mechanical in its operation it is fitted with electrical devices which are actuated thereby which justifies the title "electric pilot."

Picture frame for tombstones.

A good part of invention is directed to small articles which may serve a variety of uses; these articles of manufacture are gotten up to sell at a small price and it is difficult to classify them. In most instances nothing just like them has ever been produced and the applications for patent are based in many cases on the purposes which the inventors intend to be served by the devices. A man devised a tally block and submitted an application for a patent, the block was in the form of a hollow cube, one side being provided with an opening for holding a piece of chalk or a pencil in order to keep count in a game of cards; the suits of a deck of cards were indicated on four of the sides, the block being turned into position to indicate the trump; one side was provided with a pocket which could perform

a variety of functions; another side was fitted with a movable index and a series of numbers in order to facilitate keeping the score While the block was intended primarily for use in a game of cards the inventor set forth in his specification a multitude of uses as follows "Besides the above mentioned convenience to a card player who uses my tally block for which I pray to obtain a patent, I claim it to become a constant companion to present humanity and countless millions to come The man of business will carry it in his coat pocket and rejoice to be in position to meet any emergency, a hole in his pocket does not bother him as he can carry his loose change in the tally block, the sponge in the pocket can be changed at will and can contain the perfume which will permeate his clothes Walking about the street his nose is apt to offer a good landing place for particles of soot, the little mirror of the tally block will keep him from looking at it x-eyed and spitting on his handkerchief, the sponge will perform that duty No fear of footpads, as a corner of the tally-block on the top of his head, with a gentle pressure, will make quite an impression Coming home baby cutting teeth and cross, will change into a smiling miracle when papa pulls out the tally block and juggles with it, its attention being riveted the pain is gone Coming home late from lodge meeting, and the key being about one inch out of his reach on the transom, the tally block is as good as a step ladder In case wifey thinks she heard a noise in the cellar or wants him to look at the gas meter the tally block answers the purpose of a candle holder It is a handy receptacle for studs, buttons, pins and chewing gum To a poet with inspiration or those who want to keep record of a dream and write in the dark, nothing takes the place of the tally block In shaving the mirror can be placed at proper height, the window in a street car can be raised a little to let in fresh air by using the block as a rest Instead of applying the tongue to moisten the backside of a postage stamp, the sponge will do it without the fingers coming in contact with it No crowding in a street car, as a block in your side coat pocket makes it uncomfortable for your neighbor to sit on it The fisherman no longer bends himself into an undignified position to quench his thirst, and the coast driver has something to block a wheel Anybody can elevate himself by standing on the block to get a peep at a passing procession It can be used as a pen wiper, as a paper weight, as a receptacle for pens, a book can be placed therewith in the proper angle for reading when so desired and pages turned by dampening the fingers with the sponge

A poet's invention.

"It can be put to use to measure with by having a measure marked on the side of the block or by knowing the size of the block and turning it a required number of times The house-wife will use it, saturating the sponge with turpentine and pack it away with the clothes to keep the moths out of them, or will use it as a block to darn stockings on The orator will place it before himself on which to mark his subject matter and turn the block as he progresses in his speech The lawyer uses it in his speech to the jury to illustrate on what side of the house the murder was committed The reporter uses it when he is short of paper, and the undertaker when he finds that the head of the corpse has not the proper elevation As a novelty, my tally block contains a dictionary full of them The foregoing uses of my invention, I mainly draw attention to in order to show its varied practical utility."

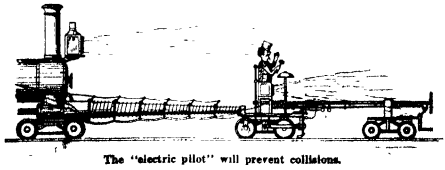
Some inventors can see the "beautiful" in their devices along with certain other advantages as the following will show: a man invented a concrete fence-post especially adapted for use on farms, the object of his invention and the accomplishment thereof being set forth as follows. "The object of the invention is to provide a fence-post which in addition to its usual function of protecting the farmer's fields against trespassing animals, also protects said fields by encouraging the little birds to come to the fields and destroy various forms of insect life that are injurious to the husbandman's trees, fruits and crops I accomplish the foregoing object and the further object of gaining for the toilers on treeless fields the inspiring, uplifting and encouraging companionship of the singing 'angels of the air,' by providing a fence-post which serves as a harbor, refuge, home and drinking fountain for a family of birds The fence-posts studding the boundaries of a field in large numbers will, accordingly, furnish a large number of homes for the birds and in a large measure take the place of boundary trees used as fence-posts as harboring places for birds." The fence-post was provided with a drinking cup which would receive some water during rainstorms, the post was also provided with a large opening which was lined with a water-proof material to serve as a nest

There is not much relation ordinarily between a table knife and a mirror, yet a mirror may be appreciated under some circumstances as the following will show "This invention relates to certain new and useful improvements in mirrors for table implements, and the object of the invention is to provide a table implement with a mirror suitably secured in the handle, so that the user of the implement may have ready at hand a mirror for the purpose of inspecting the teeth in the mouth or the mouth or other portions of the face generally at any time desired The invention is particularly designed for use in connection with table implements such as are used in restaurants, cafes, or other public eating establishments Oftentimes a patron of a restaurant finds the need of a mirror to discover a substance which has become lodged in the teeth, or for the purpose of determining whether the lips be entirely clean after eating certain foods It is not only inconvenient, but embarrassing oftentimes as well, for such patron to ask for a mirror to be used at the table In my device, however, the mirror being in the implement used by the patron during eating, may be used by him or her for the purpose indicated substantially without attracting any attention and is always ready for such use at any time desired"

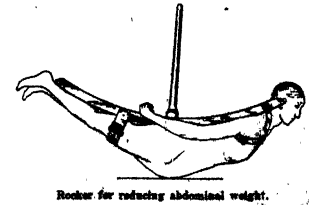
An inventor is always obliged to submit a sheet of drawings illustrating his invention. If the invention permits illustration, some arts, especially that relating to tomb-stones, offers an opportunity to the inventor to set forth his thoughts One inventor, who was something of a poet as well, set forth the following inscription.

"Here lies Windell,
An inventor by trade,
This monument you see
Is an invention he made.
A curious fact,
It has sometimes been said,
That he made it while living,
But enjoys it while dead"

Another inventor devised a picture frame to be placed on a monument which was to contain a photograph of the deceased; the frame had a movable cover on which was the following "Look at me then cover my face"



Another very practical device was a chewing gum locket, the inventor's object in setting forth his construction to the world was, "to provide a locket of novel form and construction for holding with safety, cleanliness, and convenience for use, chewing-gum, and which may be carried in the pocket or otherwise attached to the person, the improvement consisting in the provision of an anti-corrosive lining" in the locket Such an invention was undoubtedly of great value to chorus girls since it offered a ready means of cutting down one item of expense.



When an examiner picks up a new case for examination he never can tell what the examination is going to bring forth; each case involves the application of an idea which the applicant believes to be new; the idea may be impractical or may have the highest degree of utility and it is this determination, which in some cases amounts to uncertainty, that lends attractiveness to the work. Claims in an invention may be rejected by an Examiner upon proper references, which may be found in patents or publications of any sort. The citation of some references is very often objected to by an applicant who holds that the reference does not disclose the invention he claims. An applicant for a patent on a concrete chimney replied as follows to a rejection, the applicant probably being correct without really knowing it: "Solomon said, there is nothing new under the sun; consequently it is only a combination of old things that gets patented." In another case the inventor delivered himself of the following: "No one can tell what is the nature of the bars shown in the patent, and anticipation is not to be deduced from such nebulous disclosures; the prophet Nahum (Nahum 2 4) said, 'The chariots shall race in the streets, they shall jostle one another in the broad ways; they shall seem like torches, they shall run like the lightnings,' and some Patent Office *attachés* might be found to contend that the modern motor car was anticipated thus, and, while this Examiner would doubtless appreciate the error of their ways, it is almost as far fetched an anticipation as the one ironically cited above." Some applicants amend their cases hurriedly and follow out the suggestions of the examiner without consideration of the point raised; in one case an examiner believed that a specification could be improved and he wrote the applicant as follows. "Page 2 of the Specification, line 3, 'slotted' should be deleted," the applicant replied, "Page 2, line 3, cancel 'slotted' and insert 'deleted' in lieu thereof."

Chewing gum locket.

A Hot Summer in Europe

LAST July was the beginning of a period of excessive heat over western Europe The Weekly Weather Reports of the British Meteorological Office, after the first week of the month, noted "unusual" or "very unusual" warmth in nearly all sections of the British Isles The latter notation predominated, and this means that the excess of temperature was such as does not occur more often, in the long run, than once in twelve years More significant than the readings of the thermometer was the unprecedented fact that members of Parliament discarded their coats and transacted weighty business of state in their shirt-sleeves In London, the month was the warmest July for at least forty years past. In France, a remarkable period of unbroken sunshine prevailed, accompanied by excessive heat It is stated that not a single cloud was seen at Paris from July 2nd to July 24th A maximum temperature of 102 2 (Fahrenheit) was recorded at Rouen on the 22nd The hot weather continued, with but slight interruptions, up to the middle of September On August 9th a maximum temperature of 100 deg. F. was recorded at Greenwich Observatory—the highest ever observed at that institution. The heat was accompanied by drought, a water famine being experienced in many parts of England, where from July 1st to September 12th the rainfall (as measured at Greenwich) was but 30 per cent of the normal. The *Lancet*, discussing this unusual weather, finds that it was a serious factor in the recent strikes, so irritating was it to the temper of the people From the Alps come reports of dangerous avalanches caused by the melting snow and ice It is said that ice centuries old and probably never before seen by man was exposed to view under the burning sun. Small glaciers disappeared and large ones shrunk. Although complete discussions based on accurate observations are not yet available, it appears certain that the summer of 1911 will go down in history as one of the most remarkable in the records of meteorology.

The "electric pilot" will prevent collisions.

Rocker for reducing abdominal weight.

We advise you to accept the first delivery of a Cadillac which your dealer can give you

Please credit your Cadillac dealer with sincerity when he warns you not to lose your "place in line."

Many Cadillac dealers have reported sales of the entire number of cars which have been allotted to them for the 1912 season. Others have only a limited number yet to sell.

Your dealer may be confronting a similar situation.

At any rate, nothing he can tell you concerning the conditions in your own city can begin to do justice to the profound impression created throughout the world by the new Cadillac.

Prior to this year, the public has rightly looked upon the principle of automatic starting and lighting as speculative and theoretical.

But this same public remembered, when it learned of the perfection of the Cadillac system, that the Cadillac Company had never promised what it could not perform.

Indifference immediately gave way to eagerness, interest and enthusiasm.

The mere advance rumor that the Cadillac Company was about to announce its achievement made such an appeal to the public that the paramount problem confronting other cars is that which has ceased to be a problem in the Cadillac.

No one, now, is wasting any time or thought in debating the question as to whether the Cadillac electrical system is the correct and dependable system of starting and lighting.

Three thousand of the new cars, revealing the luxury of the Delco system, are stimulating the normal Cadillac demand to such an extraordinary extent that we advise you, again, to accept the first delivery your dealer can give you.

You who have not grasped their full significance—stop and consider these new comforts created by the Cadillac Electrical System

TOURING CAR, $1800

It has no crank.
Its "cranking" is done by an electric motor.

It has no gas nor oil lamps.
It makes its own electric light.

It has two complete systems of ignition, either of which is efficient for operating the car independently of the other.

But, best of all,—the three functions, starting, lighting and igniting, are all performed by one compact system, a system which is not obtainable, either in whole or in part, on any other car.

The dynamo charges a storage battery.

The dynamo is temporarily transformed into a motor and, acting as a motor, it automatically starts the engine.

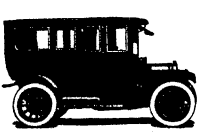
Then—it reverts again to a dynamo and generates current for lighting and for ignition.

You—press a button and push forward the clutch pedal. The engine starts.

Nothing for you to think of—except the luxury of no cranking. Reliable as the motors which drive the trolley cars.

Nothing for you to think of—except the luxury of no lamps to light; and the brilliant, steady glow of electric lights instead. Reliable as the electric lights which illuminate your home.

TORPEDO, $1900



PHAETON, $1800

ROADSTER, $1800

[illegible], Four Passenger, $2250

LIMOUSINE, Seven Passenger, $3250

CADILLAC MOTOR CAR CO. - - - - DETROIT, MICH.

Special Fabrics for Sportsmen's Apparel

Forestry Cloth (Shade No. 65) is a unique fabric, made by us exclusively, for men's and women's wear, for such special uses as camping, fishing, golfing, mountain climbing clothing It is made of *highest grade, strictly pure, all wool worsted* — which experienced sportsmen know is the only material entirely satisfactory for outdoor garments.

Forestry Cloth (Shade No 65) is a beautiful Olive Green; a more perfect shade for the purpose could not be found

Forestry Cloth (Shade No 65) withstands the roughest use, holding its shape and appearance under all conditions. It is dust and wind proof, and sheds water Adopted by the United States Government as standard for the Forestry Department.

Olivette Cloth (a fabric similar to the above in weave) is made in an attractive shade of light brown, and is especially suited for riding and driving clothes, motorists' apparel, outing suits and raincoats.

Samples of *Forestry Cloth* and *Olivette Cloth* sent upon request. And if you are unable to procure these fabrics from your tailor, we will see that you are supplied upon receipt of price. When ordering specify fabric and number of yards desired. *Forestry Cloth* $2 75, *Olivette Cloth* $3.50 per yard.

American Woolen Company's Blankets

For Camp Bungalow and General Outing purposes, meet every requirement for warmth, comfort and wear Priced from $3 50 to $10.00 according to weight, design and quality If your dealer does not carry them write us and we will tell you who does or see that you are supplied

Oswego Serge is a staple year-round fabric for men's wear, a Serge-at-its-best which — owing to its dependability — has been produced year after year in increasing quantity by the

American Woolen Company

Wm.M Wood President

Oswego Serge grows in popular favor possessing those characteristics which appeal to well dressed men, and stamp serge as the fabric of universal wear

You seek style fit and finish Let us speak for **Oswego Serge** — a master piece of the loom, possessing wear feel, hang and finish. Made of finest wool, and — quality considered — priced low

In order to be sure of the cloth when ordering a custom suit from your tailor or a ready to wear suit from your clothier insist on **Oswego Serge**

If unable to obtain **Oswego Serge**, send us the name of your tailor or clothier accompanied by money order or check for quantity desired at $3.00 per yard and we will see that you are supplied

Samples furnished on request

RECENTLY PATENTED INVENTIONS.

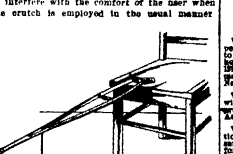
These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Of Interest to Farmers.

POTATO DIGGER.—CLAYTON W FORD, care of William St. Dairy, Findlay Ohio. This invention is an improvement in potato diggers and is illustrated with a section view of the apparatus in operation the digger is drawn through the field, with a blade or plow a sufficient depth to pass below the potatoes, and

POTATO DIGGER.

as it moves along the potatoes are lifted from the ground During transportation, the plow may be lift d out of the ground, and by means of the lever it may be held at any desired depth The arrangement of the beam of the plow moving between the frame sections prevents any lateral swinging movement of the said beam with respect to the frame, so that the plow is held directly in the rear The width of the felly of the wheel is greater than that of the rings



ALARM ACTUATING MECHANISM FOR INCUBATORS W M BRALL, Blackwell, Okla. This mechanism is certain in operation and will not be damaged by the increase or decrease of temperature beyond the points where it has been adjusted to operate The contact lever is pivoted to a rod mounted to travel in guides a spring being provided to hold the rod in a predetermined position the contact rod being connected with a thermostat by which it is operated. As the lever is operated by the thermostat it contacts with electrodes, to complete an electric circuit in which there is an electro magnet.

GIN SAW CLEANER.—H J FITZPATRICK, 158 Nellie B Avenue Athens Ga The invention refers to cotton gins and its object is to provide a new and improved cleaner arranged to permit the operator to throw the cleaner into action while the gin is running with a view to insure complete and quick removal of any lint or extraneous matter that may adhere to the saws

Of General Interest.

EXERCISING DEVICE.—E D ANGELL, 3000 Minn Avenue Corvallis Ore This exercising device comprises an elongated bag of canvas or leather or other suitable material filled with sand or other suitable substance to give it weight without rendering the same inflexible While it may be preferred to make the device flexible the body portion may be made inflexible as for instance out of wood or metal with the straps

CRUTCH SUPPORTING ATTACHMENT.—LOUIS REMICK 261 Madison Street Passaic N J This invention provides a crutch with an attachment which may serve as a support for the crutch when extended in a horizontal position and provides an attachment in a manner to avoid the same becoming an obstruction to interfere with the comfort of the user when the crutch is employed in the usual manner

CRUTCH SUPPORTING ATTACHMENT

The invention consists in adding a swinging strut or arm to the crutch which, when extended perp ndicularly from the crutch, is located into position to form a rest for the crutch when the same is extended in a horizontal position Means are provided for adjusting the length of the strut to equalize or to compensate for a seat or other place of rest of the user A perspective view of the invention is shown in the engraving

GARBAGE INCINERATOR.—J B HARRIS, 210 Stahlman Bldg Nashville, Tenn. The invention provides a sanitaire and odorless incinerator, more especially for use of municipalities, large manufacturing companies, etc., to permit convenient charging of the furnace with garbage or other refuse and continuous

LEGAL NOTICES.

PATENTS

Trade Marks
Designs
Copyrights &c.

INVENTORS are invited to communicate with **Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D C.,** in regard to securing valid patent protection for their inventions. **Trade-Marks** and **Copyrights** registered. **Design Patents** and **Foreign Patents** secured

A **Free Opinion** as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our **Hand-Book on Patents** will be sent free on request.

Cars is the Oldest agency for securing patents; it was established over sixty-five years ago.

BUSINESS OPPORTUNITIES.

A BERLIN PATENT ATTORNEY wishes to enter into business relations with a reputable and thoroughly reliable young representative resident in Washington, with a view to establishing a branch office in Berlin, with reference, to be addressed to Berlin Patent Attorney " care of this paper.

DEAFNESS.

THE DEAF HEAR INSTANTLY with the Acousticon. For personal use, also for churches and theatres. Special Instruments. Call or write for booklet and free advice. Sociable free. General Acoustic Co., 26 Beaufort St. Jamaica, N Y. Only Perfect Sound. 8 Rue d'Hauteville.

FOR SALE

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to step into a permanent business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Proprietary Realty Co.—Operators Real Estate Company, 1736 Marden Building, Washington D. C.

OLD COINS

OLD COINS.—$7 15 paid for rare date 1856 quarters, $50 for a 1804 Keep all money dated before 1895, and send 4c at once for New Illustrated Coin Value Book 4 x 7 It may mean your fortune. Clark & Co., Coin Dealers, Box 48, La Roy N Y

PATENTS FOR SALE

ATTENTION.—Railroad locomotive spark arresters, patented and for sale Railroad free attendance and prohibitory smoke stacks Also boiler compounds and steam engine cylinder lubricators in connection. Albert Lawrence, Soldiers Home, Hampton Va.

PANAMA CANAL, Rubber Stamps Novel and unique made of metal. Garrido or royalty Patented Mfd. For further particulars address, Henry Stevens, 119 Sixth Street, Milwaukee, Wis.

WANTED

WANTED.—Ship draftsmen, pay from $5.64 to $6.60 per diem, and assistant ship draftsmen, pay from $4.32 to $5.40 per diem. A competitive examination will be held at the Navy Yard Philadelphia, Pa. September 11, 1911, for establishing an eligible register of ship draftsmen For further information address "Commandant, Navy Yard, Philadelphia Pa."

WANTED mechanical articles—Wish to correspond with men who can write articles on aviation, saloon, bills wrestle and other machines; also on popular style. Address, Mechanics, Box 773, New York.

WANTED.—A man or woman to act as our information reporter, all or spare time, $25 to $100 per month. Nothing to sell. Send stamp for particulars. Press Association, 79 Associated Bldg Indianapolis, Indiana.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party making the inquiries. There is no charge for this service. In every case it is necessary to give the currency of the inquiry. Where manufacturer do not send catalogues, the inquiry may be repeated. MUNN & CO., Inc.

SWAN'S
Fountain Pen
For XMAS
Is a gift that is appreciated by men, women and children the world over Made in chased vulcanite, sterling silver (filigree or engraved) rolled gold and solid gold in different styles

The "Gold Top Feed" which shows on the upper face of the nib in the illustration, keeps the pen moistened with ink at all times and insures instant writing

The "Ladder Feed" on the under face of the nib, as the cut illustrates supplies the ink steadily without skips, blots or overflow of ink.

The "Screw down Cap" is a device that screws down tight over the nib, creating an ink tight chamber, making it impossible for the pen to leak

SWAN Safety Pen

Can be carried in your pocket, suit case or handbag in any position, horizontally or upside down The "Swan Safety" will never leak.

For sale at all stationers and jewelers. Prices $2.50, $3 50, $4 00, $5 00 and up We will send illustrated price list on request.

MABIE, TODD & CO.
17 Maiden Lane, 124 S. State St.
NEW YORK CHICAGO

and reduction of the liquid and solid matter, to insure complete combustion of matter and utilizing products of combustion for heating boilers for generating steam to be used partly in the furnace, and a supplus for power purposes for the production of electric lighting, etc.

PYROPHORIC METAL ALLOY.—G F HOFMANN Bayerstrasse 87 Munich Bavaria Germany In accordance with this invention the pyrophoric metallic alloy of manganese and antimony has only added to it a small quantity of metallic cerium for instance, about 5 per cent of metallic cerium suffices to considerably reduce the hardness of the manganese antimony without injuring its pyrophoric property It sparks better than the simple antimony and manganese alloy it is more easily fled and remains unaltered in the air

FOLDING TOOTH BRUSH.—S. B LUTICA, 400 Columbia Bldg Portland Ore This invention relates to tooth brushes, and it has for its purpose one which may be folded and carried in the pocket, the device having a box for containing tooth powder which is permitted to reach the brush member pivoted to the box through an opening therein

BAIT FOR CATCHING ANIMALS AND THE LIKE.—C. H FRETER Laddonia Mo In the use of this composition the same can be used in connection with any common animal bait, such as meat and the like or the composition can be used alone When used in conjunction with animal traps it serves to attract the animal to the trap and in this manner presents an efficient and easily prepared bait.

Hardware and Tools.

WRENCH.—A. BRAUN Kopprasch Agent, Vienna Austria Hungary The is made of a handle provided with a jaw extending at an angle from the handle and having thereon a gripping ing for engagement with the peripheral surface of an object to be turned or adjusted and a second jaw provided with a gripping ing for engagement with the peripheral surface of the object, the said second jaw being pivotally mounted on the handle and in contact with a spring mounted on the handle.

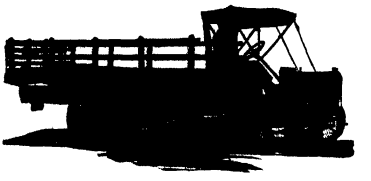
DESK REMINDER.—G W WRIGHT Schoeuer Bldg 788 Broad Street Newark N J An object of this inventor is to provide a device which will hold a plurality of memorandum tabs in separate readily accessible positions whereby they can not nly be readily removed and inserted but also can be at least partially visible so as to be distinguishable one from the other

WRENCH.—EDWARD L. BROWN Box 89 Virginia City Nev This engraving presents a side view partly in section of a wrench showing the jaws open The handle may be preferably of metal channeled out in its sides. The tapered forms of jaws are useful in that they will hold the end of the wrench on the pipe after the jaws are adjusted and there is no danger of their slipping off The said

PIPE-WRENCH

ing jaws may be adjusted to fit upon a pipe by turning the screw and the last may be slacked to allow play between the jaws so the wrench will work freely around the pipe, and if very thin the throw of the sliding jaw can be regulated so as not to crush the pipe The inventor will communicate with reliable parties on request in relation to manufacturing the wrench on a royalty basis

Heating and Lighting



WARM AIR REGULATING HEARTH.—E B LORACH 4715 Haywood Place Denver Colo In this structure the inlet opening for warm air is adjacent the bottom of the hearth and is covered by a plate which has a portion of its surface perforated to permit passage of the warm air from the inlet pipe through the hearth into the room or apartment. The perforated portion is controlled by a slide or damper which uncovers a greater or less number of the perforations as desired

FLEXIBLE PIPE COUPLING.—W A CRAMOND 387 E 19th Street, New York N Y The invention relates to improvements in pipe couplings for use generally in connecting relatively—movable pipes through which a fluid is delivered, the special form of coupling being designed for use in connecting steam pipes which carry the steam to multiple waterless cups of telescopic gas holders, to prevent the freezing of the water within the cups during winter

Household Utilities.

BATH ACCESSORY.—F HESS, 321 Fifth Avenue West, Kalispell, Mont. This invention provides a sanitary towel supporting frame to be readily adjusted to a bathtub of usual construction the frame being provided with means for securing the towel firmly in the frame; and provides a device adapted for attachment to the inclined end of the bathtub.

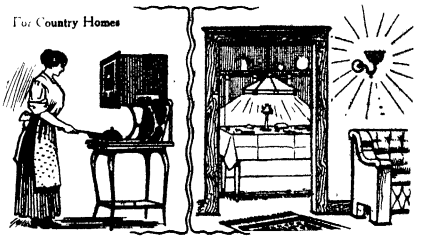
TOWEL FRAME BRACKET.—W. J. DALE, 314

What Motor Trucks Mean

IF you are not using motor trucks, we take it for granted that you do not understand the benefits to be derived from them Possibly you have the wrong viewpoint—perhaps you have been making too many comparisons with the horses and not really investigating what the truck meant to you as a machine to perform certain work The individual or firm that has a better delivery system has an advantage—the kind of business doesn't matter—service is appreciated universally If The White Company can place in your hands a more efficient means of making deliveries, they have given you an opportunity of extending your field—of broadening the horizon of your product—of making good—where you had been unable to go before

White Trucks Known for Performance

GO into any large city in the United States—ask the men who have the largest delivery problems, to see what they know about these White trucks Almost regardless of whether they own them or not, you will find that they know their record for splendid performance To the man about to invest in trucks, a list of White owners will appeal as almost a directory of the big business men They have invested their good money in White trucks and their endorsement is the fact that they are continually increasing their equipment No one buys and buys again the thing that fails to stand the test We could tell you why—because it is all in the designing—in the building—in the care we take in the production of the truck The important thing to you is that they do perform—that White trucks satisfy their owners—and, therefore, must be the kind that you want



1500-lb delivery wagons 1½-ton 3-ton and 5-ton trucks—all with a universal type of power plant

Let us submit a solution of your delivery problem It will entail no obligation

The White Company

838 East 79th Street, Cleveland, Ohio

For Country Homes

Cooking Fuel and Illuminating Gas
Made at Home with a Little Machine Like This

ABOUT once a month this machine must be refilled with gas producing stone and wound up like a clock.

When obediently it stands idle until you start to cook or turn on the lights

Then, with no attention whatever, it gets busy and makes gas automatically—just enough to keep your stove and your lights going

The stone, known commercially as "UNION CARBIDE," gives up its gas when the machine drops a few lumps into plain water—a little at a time as the gas is wanted.

The gas is genuine Acetylene Burned in handsome chandeliers it gives a flood of brilliant pure white light

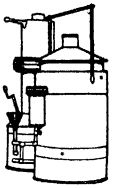
Burned in the kitchen range, it makes a hot blue fire that can be instantly turned up or down, on or off.

For both cooking and lighting it is used exactly as city gas is used by over twenty million city people.

As a fuel, it flows right into your stove without handling and burns without soot or ashes

As a light, its white, sunlike beauty is unrivaled Reflected from handsome globes suspended from brass or bronze chandeliers, it supplies the up to date city like appearance of refinement and elegance which the average country home lacks

Moreover, it is not poisonous to breathe, and the flame is so stiff the wind can't blow it out.



The UNION CARBIDE you dump in the machine once a month won't burn and can't explode

In a nutshell, one of these gas machines installed in the cellar or an out building of a country home solves the *lighting* and *cooking* problems for all time

And they are so easy to install in any home without injuring walls or carpets that there are now over 180,000 Acetylene Gas Machines in actual use

We manufacture and our agents arrange for installing thousands of them every month in all parts of the world.

There are, of course, many crude imitations of our machine on the market, but the genuine is easily distinguished by its name and our trademark

"Pilot" Acetylene Generators

On the first return mail we will send you free literature telling how Cornell University has been growing plants by our light—why oculists recommend it for eye strain—why the Insurance Engineers pronounced it much safer than kerosene—how this lights can be placed in barns and outbuildings—how they can be equipped to light up without matches—and how the gas range shortens kitchen hours and makes cooking a pleasure.

With these booklets telling all this wonder story, we will send figures showing how little a "PILOT" lighting and cooking equipment will cost in your case.

Just write us how many rooms and buildings you have to light and where you are located. Address your letter to the ACETYLENE APPARATUS MFG CO—South Michigan Avenue, Chicago, Illinois.

HOW TO BUILD A 5 H. P. GAS ENGINE AT HOME

In *Scientific American Supplements*, 1641 and 1642, E. F Lake describes amply and thoroughly how a five horse power gas engine can be built at home. Complete working drawings are published, with exact dimensions of each part. Price by mail for the two Supplements, 20c. Order from your newsdealer or from

MUNN & COMPANY, Inc. *Publishers* 361 BROADWAY, NEW YORK

Your Important Papers will not get torn or crushed in a MULTIPLEX FILING CABINET

The pictures of the two drawers at the left, tell the story. The one drawer is crowded with sagging mass of unsupported folders—in getting them back, papers are easily crumpled and torn.

The other drawer has our *Patented Inside Metal Partitions*, which do away with crowding and sagging, and always keep the *folders upright* and easy of access.

No Follower Block—True Vertical Filing
No Waste Space

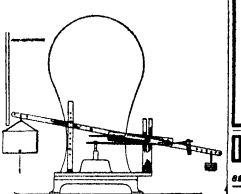
Multoplex Cabinets save money and set a new mark of filing efficiency.

They enable more rapid filing of folders—
—permit correspondence to be found and taken out more quickly
—prevent crumbling tearing and mutilating of letters
—reduce the number of misfiled and lost letters
—permit drawers to be filled to capacity without overcrowding
—effect a big saving by doing away with guide cards and permitting the use of lighter, less expensive folders.

Write for Our Booklet—"Faultless Filing"

Learn the full particulars about these new filing features that mean much greater efficiency at less expense. Please mention your firm name and in what capacity you serve. Write for the booklet today.

CANTON MFG. CO., 1204 S. Second St., Canton, Ohio



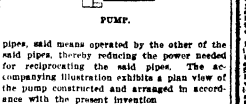
N Main Street, Mason City, Iowa. This invention is an improvement in sink frame brackets, and the aim is to provide a bracket which is especially adapted for supporting sinks, and which may be expanded or contracted, to fit sink frames of varying sizes, and wherein means is provided for locking the parts in adjusting position.

WATER CLOSET FIXTURE.—T. F. WARD, care of T J RYAN, 6 Howard Street, New York, N Y. In the present invention the principal object is the provision of a fixture for the usual water-closet bowl, which automatically closes over the bowl to prevent the emission therefrom of disagreeable odors or sewer gas, and to conceal the interior of the bowl.

Machines and Mechanical Devices.

ATTACHMENT FOR SHUTTLES.—G. PAVIA, Allentown, Pa. This attachment severs the thread so as to prevent damage, when an unusual pull is had on the thread. The attachment may be secured to shuttles in ordinary use, which may be set so as to allow the thread to feed from the bobbin just so long as the loom is working properly, but when, from any cause an unusual pull is had on the thread or a knot or tangle in the thread reaches the attachment, the thread will be automatically severed so that the shuttle will run free

AUTOMATIC RAM STARTER.—J. F. T. BJERKNAES, St. Paul, Ore. The object here is the provision of means in connection with the ram for opening the impetus valve to stop and start the same in accordance with the head of the water, stopping the ram when the water falls below a predetermined point and starting it when the water has a sufficient head The illustrated figure shown herewith represents a side view of the improvement, the ram of which is of any usual



AUTOMATIC RAM STARTER.

or desired construction and the impetus valve thereof is contained in the chamber at the base of the ram

FLYING MACHINE.—E. J. CRAWFORD, 1208 N 45th Street, Seattle, Wash An object of this invention is to provide a lighter-than-air machine which is provided with a safety device so as to prevent a rapid descent which might injure the aviators This device is in the nature of a parachute which may be shifted so as to sustain the flying machine so that its descent will be gradual

PUMP.—KARL F. GERHARD, Hatton, Wash The principal object which the present invention has in view is the provision of a pump having mutually balanced stand pipes of indefinite length, the said stand pipes being each provided with pumping means for increasing the height of the column in each of the said

PUMP.

pipes, said means operated by the other of the said pipes, thereby reducing the power needed for reciprocating the said pipes. The accompanying illustration exhibits a plan view of the pump constructed and arranged in accordance with the present invention

SPUDDING DEVICE FOR WELL-BORING MACHINES.—G. P. RIGGS, Box 411 St. Mary's, West Va. This invention provides a boring bit reciprocating device having an amplified stroke and mechanism for operating the same, provides means for reducing the rotation of the lifting sheave and the travel of the drill rope thereon, without diminishing the stroke thereof, and provides an extensible rigging for boring operations.

NECK GROOVING ATTACHMENT FOR BOTTLE MOLDING MACHINES.—E JOHNS, 611 Walnut Avenue, Fairmount, W. Va. Primarily, this invention consists in providing a separate mechanism for grooving the neck of a bottle, mounted upon one or the other of the primal molding tables, to impart the groove in the glass prior to its initial blocking, thereby avoiding reheating.

AEROPLANE.—C. M. WARNER, Urbana, Ohio. This inventor provides a substantial

Either type as above, silk, 50 cents; lisle, 25 cents. At stores everywhere. Sample pair sent postpaid on receipt of price.

Boston Garter

"For thirty years the standard—from first to last the best." Holds up the half hose as smooth as your skin. Guaranteed against imperfections. Look for the moulded rubber button and the trade marks on the loop.

GEORGE FROST CO., MAKERS, BOSTON

Maxim Silencer

In use by the United States Army

Checks the muzzle blast, preventing report noise and recoil Wonderful aid to marksmanship Makes rifle practice possible anywhere. Attaches to any rifle. Write make, model and calibre of your rifle (giving dealer's name). We will tell you what Silencer you need, price, etc.

MAXIM SILENCER, Hartford, Conn.

ICE MACHINES Corliss Engines, Brewers and Bottlers' Machinery

The VILTER MFG. CO.

890 Clinton Street, Milwaukee, Wis.

Little Things that Make a Big Winner

L. C. Smith & Bros. Typewriter

(BALL-BEARING, LONG-WEARING)

Typebar ball-bearings made like a watch. Carriage, to move at a feather touch and stand at any point, unshakeable. Escapement, lightning swift, in its getaway from the operator's nimble fingers. Touch, smooth, easy, with snappy response. Shift-key lightened to one-third ordinary pressure.

Careful, painstaking application to such fine details of construction have given you a typewriter that gets *big results* and does satisfactory work—all kinds of it—without a bit of fuss or needless effort.

Your stenographers will like the L. C. Smith & Bros. Typewriter because it enables them to do better work, do it easier, and do more of it. You'll want it, yourself, for the same reasons and also because, on account of the ball-bearings throughout, it keeps in better order and gives much longer service.

Send for "Another Decision by Experts" telling how the Savage Arms Company chose a typewriter equipment.

For Fifty-five Years Manufacturers of Superior Revolvers

[illegible] St., Springfield, Mass.

whereby aeroplanes are enabled to start their flight from a resting position; provides means for mechanically lifting the aeroplane to an inclined position while in contact with the ground or starting station and provides manually operated mechanical means for initiating the flight of an aeroplane.

DRILLING MACHINE.—K. L. J. FRASER, Sandpoint, Idaho. The aim in this case is to provide a machine more particularly adapted for drilling holes in tree stumps and the like, preparatory to blasting the same. Further, to provide a machine mounted to swing on a frame, so that the drill can be used at various angles and positions, depending wholly upon the work to be drilled.

Railways and Their Accessories.

SELECTIVE SWITCH MECHANISM.—A. V. MCFARTLAND, 16 Perry Street, Newark, N. J. This invention has reference to a device whereby the motorman on a car as he approaches a switch leading to a plurality of different tracks, can operate a mechanism on the car which actuates the switch so as to divert the car in the direction in which he desires to go.

SAFETY APPLIANCE FOR AIR BRAKES.—A. B. LEETWICH and C. N. MARKLE, 1413 E. 7th Street, Pueblo, Colo. The object here is to produce a brake which is simple in construction and which can be controlled in its operation by pneumatic means, a more specific purpose being to provide mechanism whereby a brake is held unapplied by pneumatic and mechanical means, and is applied by spring pressure when pressure in the service or train pipe is sufficiently reduced.

Pertaining to Recreation.

GUN.—AUGUST REISTEIN, 48 Stuyvesant Street, New York, N. Y. The purpose of this invention is to provide a new and improved gun, arranged to permit of conveniently turning the barrel of the gun in a horizontal plane for taking the desired aim, and to permit the

GUN.

user to readily propel and retract a striking or a shooting plunger without danger of disturbing the aim. For the purpose mentioned, use is made of a barrel containing two spring-pressed plungers, of which one on being released actuates the other plunger. The engraving herewith gives a view of the longitudinal central sections of the gun.

TOY.—T. D. FLOTO, Box 17 Station S, Brooklyn, New York, N. Y. This invention relates to toys having a ball or roller adapted to wind up and unwind on a cord held at one end by the user of the toy. The object is to provide a toy in which the ball is rendered exceedingly smooth, and the necessary weight is provided to insure a proper unwinding of the ball and re-winding on the cord by the momentum caused by the unwinding of the ball.

Pertaining to Vehicles.

VEHICLE TIRE.—F. A. SCHULTZ, care of Mattson Rubber Co., Lodi, N. J. Among the principal objects the invention has in view are to provide a resilient filler wherein the air contained in the tire is circulated to prevent local overheating of the tire casing and filler, to provide auxiliary resilient members adapted to augment the carrying capacity of the tire and the resilient quality thereof; to provide a filler for an automobile tire formed from a number of removable and renewable sections, rendering the tire capable of economical and simple repairs; and to provide means to release or imprison the locking members of the tire, and to augment its resiliency.

AUTOMATIC CRANKING MECHANISM.—J. P. PETIT, 873 N. Commercial Street, Salem, Ore. The improvement is in cranking mechanism or devices used on automobiles, and the aim is to provide a novel construction whereby the engine can be cranked from the driver's seat of the car in a perfectly safe manner, and by means which will avoid the possibility of any injury to the driver by the action of the engine.

ROAD MACHINE.—M. M. SIGMUND, Pala, San Diego Co., Cal. This invention provides a scraping blade and supporting means connected directly with the draft team or mechanism; provides carrying wheels and means for varying their angle of operation; provides for the carrying wheels a supporting table the operation whereof serves to vary the lift of the body by adjustment of the said wheels; provides carrying wheels and mechanism therefor whereby the same may be turned to vary the angle of a scraping blade; and provides carrying wheels and body structure adapting the machine to be turned upon a self-contained center.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

You can safely rely upon a heating equipment that has furnished 200,000 homes with adequate healthful, economical heat during the past 35 years.

That is the record for Pierce Boilers and Radiators which today offer a perfect application of steam or hot water to the problem of home heating. Every heating condition is successfully covered in the Pierce line of boilers. Any house, no matter how it is built, what it is built of, where it is located, or what its size or arrangement may be, can be made comfortable with the least trouble and cost by means of a Pierce System—properly installed

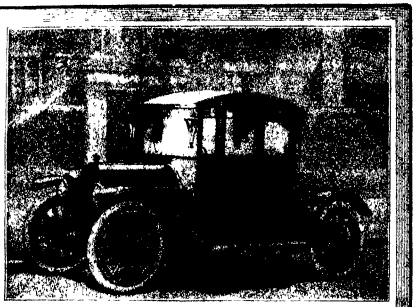
PIERCE MARK

"COME On In Boys;

The Soap's fine"

PUMMO SOAP *is* fine for every worker, whether in factory, office, field or kitchen. In it vegetable oils, fine Italian pumice and glycerine are combined to make a soap which takes off, in a twinkling, the grime of a hard day's toil. It leaves the hands soft and smooth.

You will be delighted with PUMMO SOAP. It is so clean, thorough, exhilarating. So will your women folk, for it is just as efficient for cleaning from their hands the stains of the kitchen.



PUMMO SOAP costs but 5 cents. At grocers and druggists.

If your dealer does not have PUMMO in stock, fill out and mail the coupon and we will send you, FREE, a sample of sufficient size to enable you to thoroughly test its merits.

Beautiful HAYNES Cars

FOR nearly twenty years the Haynes has had all the sturdiness, engine-excellence and superior construction that the best automobile experience and skill could command. And now for 1912 we have added grace of lines and beauty of finish and equipment not surpassed by *any* automobile at any price.

Haynes Model 21 Colonial Coupe has scored a triumph since its introduction a month ago. It will be one of the most popular cars on American boulevards this winter. Haynes Newport and Berlin limousines reflect *character* in every detail.

All Haynes enclosed bodies are *positively* interchangeable with Haynes touring bodies. Model 21 Colonial Coupe for this winter and the same chassis with a roomy 5-passenger touring body for next summer makes an ideal combination at a price only slightly higher than the Coupe alone.

The Haynes for 1912 offers a complete line of body types, on our two standard chasses: Model 21, 40 h. p., 4¼x5¼ motor, 120 in wheel base. Model Y, 50 60-h. p., 5 x 5¼ motor, 127½ inch wheel base. Prices $2100 to $3900 fully equipped.

Write for 1912 Haynes catalogue, and name of our dealer nearest you. Address

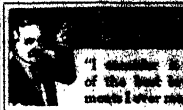
Needed Reforms in Patent Procedure

(Concluded from page 454.)



or seventy-five dollars a day for their services in preparation and while testifying, it can readily be seen how enormous the expenses of patent litigation may become under this mode of producing evidence. The system places the poor inventor at the mercy of his rich adversary and, sad to relate, renders it possible for lawyers with easy consciences to protract examinations for the mere purpose of multiplying *per diem* charges.

The impression should not be gained, however, that this system of producing evidence is peculiar to patent cases. It extends to all causes brought on the equity side of the court, but its evils are perhaps not so frequently manifested in other classes of cases. There is a universal cry for a remedy. President Taft in his messages to Congress has referred to it. Three members of the Supreme Court of the United States, namely, Chief Justice White, Mr. Justice Lurton and Mr. Justice Van Devanter, have been assigned to look into the matter and have conferred with committees appointed from the bars of the various Circuit Courts of Appeal with the view to ascertaining if something cannot be done by way of curing the evil. No definite result has yet been reached, but it is the expectation of the bar that, at an early day, the General Equity Rules will be so modified by the Supreme Court, under the power given that court by the statute, as to require that the testimony of all witnesses living within the jurisdiction of the trial court shall be taken in open court, in the presence of a judge, and that only the testimony of such witnesses as live beyond the reach of the process of the court (i. e., one hundred miles, or to the limits of the district) may be presented to the court by way of depositions. Such a change of practice as this may, and doubtless will, develop difficulties that will have to be met as they arise, but it is believed they will be met and that the net result will be that the volume of testimony taken will be very much reduced and that generally the dispatch of business will be facilitated and the cost of litigation very materially decreased.

Time and space will permit of an allusion to but one other need of our patent system, namely, the establishment of one great Court of Patent Appeals to which appeals from all the trial courts may go and whose judgments as to the validity of the patent in view of all defenses actually raised against it, will be final and conclusive and, in operation, coterminous with the whose territory of the United States.

At the present time, an appellate court called a United States Circuit Court of Appeals is provided in each of the nine judicial circuits, and while the judgments of this court are final, as to that circuit, they have no force beyond the limits of the latter. The result is, that a patent may after most strenuous litigation, be held valid and infringed in one circuit, and, on substantially the same record, be held invalid and not infringed in another circuit.

Such a condition of affairs has become intolerable and for many years past Congress has been importuned to divest the Circuit Courts of Appeals of their appellate jurisdiction in patent cases and to create a new appellate court for the disposition of all patent appeals. There seems to be a general recognition of the necessity for such a court, but the difficulty of reconciling the various plans that have been suggested and advocated as to methods of organization has so far prevented a favorable outcome. President Taft, in his address to the American Bar Association last August, at Boston, made extended reference to the matter and suggested that the recently created Commerce Court, composed of circuit judges, might take over the jurisdiction of patent appeals and thus solve the problem. It remains to be seen whether his suggestion will be acted upon by Congress. The plan advocated for so many years by the American Bar Association of having a new and independent court composed of a permanent presiding judge and four associate judges selected, because of their demonstrated aptitude to deal with patent cases, from the U. S. Circuit and District benches, would seem to be more nearly ideal.

"I maintain Rooms of the best hotels in winter cold."

That's how a prominent bank president who owns a JEWELL Heat Controller regards its value as an economizer.

But over and above the money-saving

The JEWELL HEAT CONTROLLER

adds to your comfort, lessens your labors, and makes your heater keep your home at the *right temperature*.

Polar the indicator to the temperature you want. The Jewell automatically opens or closes the drafts whenever necessary to assure an even temperature. The clock attachment enables you to keep the house cool during the night and have it warm when you rise.

Guaranteed mechanically perfect for 25 years. Adjustable to any system of heating. Installed for 30 days' free trial.

Write for the name of the JEWELL dealer in your town. He'll send it, together with a copy of our valuable and interesting booklet, "The House Comfortable."

Don't Pare a Corn

Paring is risky, and it's only a makeshift. The corn should be removed in a painless, harmless way.

Apply a Blue-jay plaster. It is done in a jiffy. The pain of the corn stops instantly. Then the bit of soft B & B wax gently loosens the corn, and it comes out in 48 hours.

No soreness, no pain, no discomfort. You forget you have a corn. Fifty million corns have been removed in that way. Let it take out yours. Get it now.

A in the picture is the soft B & B wax. It loosens the corn.

B protects the corn, stopping the pain at once.

C wraps around the toe. It is unnoticeable.

D is rubber adhesive to fasten the plaster on.

ARE YOU Satisfied With Your Income?

Would $500, or more a year on the side be an object to you?

You can easily make and exceed that amount in the poultry business without interfering with your regular work. Consumption of poultry products is fast over-taking production. The producers can not keep abreast with the needs of the increasing population. Now a billion dollars are spent annually for poultry and eggs. Why don't you get a part of that enormous sum? You can, if you will.

"Side-Line Poultry Keeping"

$1,088.05 is the amount F. H. Dunlap of West Salisbury, N. H., cleared from his hens in 1910, and did not devote more than two hours a day to them. You can learn the secrets of his success in the book "Side-Line Poultry Keeping."

$1,009.31 was the net profit made by R. A. Richardson, Haverhill, Mass., in 1910, who attended to his regular work as a shoe cutter. The details of his success are also told in "Side-Line Poultry Keeping."

This Reliable Book is by Edgar Warren, who writes in such a simple, pleasing manner that any novice can understand and follow the instructions which lead eventually to success. It is of special value to the person who desires to add several hundred dollars to his annual income without interfering with his regular work. It covers every detail of the hen business and is a ready reference for hatching, brooding, selecting layers, feeding for growth and fattening eggs dressing, shipping selling treatment for internal and external ailments, Laying Down Eggs for perfect keeping, etc., etc.

Special Offer: Price 50c. or book and American Poultry Advocate 1 year, 75c. or book and 2 years subscription for $1.00 or premium for two yearly subscriptions at 50c. each. Sample free. Poultry book catalog free. Our paper a handsomely illustrated 44 to 120 pages. 50c a year. 3 months, 10c.

Government Sale of Indian Land

In November the Government begins selling at auction, in tracts of 10 to 640 acres, the last of unallotted Choctaw-Chickasaw lands, located in Oklahoma; appraised at $1 to $15 per acre; terms—20% cash, 2% a year, 5% in two years. The marvelous fertility of the State is demonstrated by recent yearly crops from wheat which averaged 20 bushels, and land values are soaring. Timber, natural gas, oil, coal, asphalt, zinc and lead resources are undeveloped.

We know these lands and will buy them on straight commission for persons unable to attend sales. For homes, profitable investment or speculation this opportunity is unequaled. No promoters' profits. Send 4c coin for map and particulars.

Edison's Pioneer Work

(*Concluded from page 454.*)

series with the armature, and could be "plugged" in and out of circuit by the motorman as he needed

In the same year, 1880, the generators were compound-wound for better regulation under changes of load, and three cars were put in commission as rolling stock. One of these was an open car with awning, and two park benches placed back to back Another was a flat car for freight, and the third was a box car, dubbed the "Pullman," on which Edison tried a system of electro-magnetic braking covered by patent The road attracted a great deal of attention, was visited by celebrities, and was freely described in the papers The SCIENTIFIC AMERICAN of June 6th, 1880, gave an excellent account of it, and a little later the New York *Daily Graphic* described also the electric locomotive with six-foot drivers, capable of working up to 300 horse-power, which Edison designed for use on the Pennsylvania Railroad between Perth Amboy and Rahway But President Frank Thomson of the Pennsylvania could not "see it;" nor could his engineers What would they say of the electrified Pennsylvania entrance into New York to-day?

When Edison went out to Wyoming in 1878 with his transmeter to observe and help register the transit of Venus, he had noted the long hauls of the wheat farmers with their grain A drawing of his of May, 1879, shows electric power plants operated out on the prairies by wind power, to give these farmers light electric traction Henry Villard had the same general idea, and in 1881, after this successful demonstration of 1880, joined issues with the young inventor and put up between $35,000 and $40,000 for a trial of the scheme The Menlo Park pioneer line had been extended to a mile and was now made nearly three miles in length in 1882 The construction approximated standards as to gage and material and was solidly built There were three trestles, one of which was nearly 250 feet long and 10 feet high The rails were insulated from the sleepers by two coats of japan varnish baked on them in the oven, and by pads of tarred muslin The ends of the rails were electroplated to give proper contact for copper bonds and fish plates The conductors were underground as before There were two turntables, a freight platform, three sidings and a car barn The line ran through a rural district three miles south to Pumptown

Two new electric locomotives were built, and following the traditional lines of conventionality there were given the full regalia of headlight, cab and cowcatcher Little change except by way of refinement was made in the electrical arrangements from those of 1880 One locomotive was designed for passenger service and weighed five tons, the other for freight, with single reduction gears, weighed about ten tons As many as 90 passengers at a time were hauled by the smaller locomotive in 1882 The contract speed was 60 miles an hour The capacity of the freight locomotive per contract was 10 tons, speed negligible. Mr Villard agreed to enter into negotiations. If the tests were successful, for an initial 50 miles of electric railroad in the western wheat regions, as right-angled feeders to the Northern Pacific line Possibly all this would have been done, but the Villard panic came—and the farmers of the northwestern wheat fields are still without the service that was planned for them, although many thousands of farmers now depend upon trolley lines for getting their milk, fruit, eggs, and other produce to the distant market Edison was a great admirer of Villard; and as the directors of the old Edison Electric Light Company refused to have anything to do with the electric railway or the contract, Edison treated the money advanced from Villard as a personal loan and repaid it out of his own pocket Villard was worthy of such esteem. He was a great leader and pioneer and visualized the whole Pacific Coast development while all America was still looking eastward. At an early moment he believed that the mountain division of the Northern Pacific could be operated electrically, and acting on his request Edison devised a third-rail-and-shoe system such as is now familiar and set it up in his works yard at Orange The steam railroad engineers refused to have anything to do with it as impracticable, and one

NEW YORK CENTRAL LINES

can hardly blame them; but it is here and every year will see more of it.

Edison has never made anything out of all this or other pioneer electric railway work; but that is not a unique experience for an inventor. Had he "stayed in the game" he might have recouped some of his losses financially, but he was very busy elsewhere and the young art was already moving forward with swift and tremendous strides. His first electric locomotive is now a treasured relic at the Pratt Institute in Brooklyn, N Y The remainder of the little primitive system has rusted and faded away, or lies around, as shown, in innocuous oblivion, at one with the pyramids and castles and ancient cathedrals.

Perpetual Motion

(Concluded from page 468.)

Ernest Elie-Bessler Orphyrreus upon what are conceived to have been substantially the foregoing principles. It is related that Orffyreus, as he is generally called, made one machine about 1715, but broke it up because of the tax imposed upon it by the government of Hesse Cassel A second apparatus was made and exhibited to the Landgrave. It is said that this machine, which outwardly appeared to be a drum 12 feet in diameter and 14 inches between faces mounted upon an iron axle, upon being started with a smart impulse—in either direction—would rotate faster and faster until the periphery was moving at the rate of about 16 feet per second. It was claimed, so it would seem, that the wheel having been set in motion in the chamber of the Landgrave and kept there under seal, was still going after the lapse of two months The machine was stopped, so it is said, to prevent undue wear However, the inventor kept his secret very close. The Landgrave, having made him a fine present, was shown the interior But he had to promise not to tell what he had seen nor to make use of his knowledge. In fact, Orffyreus demanded a payment of about $100,000 for his secret Prof 's Gravesand of Leyden was employed by the Landgrave to investigate the machine, in so far as one might be able to do so without opening up the interior. In a letter to Sir Isaac Newton in connection with this matter, he describes it as made of "several cross pieces of wood framed together, the whole of which is covered over with canvas, to prevent the inside from being seen Through the center of this wheel or drum runs an axis of about six inches diameter, terminated at both ends by iron axes of about three-quarters of an inch diameter upon which the machine turns I have examined these axes, and am firmly persuaded that nothing from without the wheel in the least contributes to its motion When I turned it but gently, it always stood still as soon as I took away my hand, but when I gave it any tolerable degree of velocity, I was always obliged to stop it again by force, for when I let it go, it acquired in two or three turns its greatest velocity, after which it revolved for twenty-five or twenty-six times in a minute. This motion it preserved some time ago for two months, in an apartment of the castle, the door and windows of which were locked and sealed"

It seems that no one who had the $100,000 ever agreed to pay it over upon the condition that the apparatus should be "found to be really a perpetual motion" Whether Sir Isaac Newton replied to Prof 's Gravesand or not, I do not know.

A device probably similar to that just described is illustrated in Fig. 9. There is a rotatable wheel upon whose circumference arms are hinged at equal intervals Weights are attached at the outer ends Stops are so arranged that the movement of an arm on its hinge is limited to an angle on one side of which is a prolongation of a radius All the arms are arranged to swing from a radial direction in a circular direction contrary to the hands of a clock. By attending to the figure, it will readily be seen that on the right the weights *A*, *B* and *C* are advantageously situated to produce a clockwise motion, even though somewhat resisted Because of a preponderant advantage which it might seem reasonable to suppose continually to attach to the weights on the right, we might look for perpetual motion.

What may be regarded as a variation from this device is exhibited in Fig. 10. Here the arms consist each of a number

of links hinged together. A trough *D C* is arranged to permit the weights, which are here loose balls, to roll from one side to the other. This trough is fixed in position. By these means, the weights of the upper left-hand quadrant are entirely removed or brought in close to the vertical diameter When a weight rises to the point *D* it rolls off by way of a trough to an arm previously crumpled up but now outstretched.

The great thing overlooked in such devices is the question of velocity. A ball which falls from top to bottom will acquire, *apart from friction, just so much* momentum This is due to the vertical distance passed over, and will not vary however tortuous the real path may be The reason that it is due to the vertical distance is because that is the direction in which gravitation acts. Similar considerations apply to the upward movement It is the vertical distance that counts because that is the direction in which gravitation has to be overcome Of course, this is precisely the same from top to bottom as from bottom to top

I may be permitted to call attention to a device somewhat similar to those just described. (See Fig 11.) The figures to right and left of the vertical diameter are the same in number As it is obvious that a number of 8's preponderates over an equal number of 6's, the wheel must, of course, turn clockwise. Study this device well, it is as good as any of the others.

The devices described so far all aimed at gaining a balance of power from the effect of gravity. Other inventors have sought to utilize the properties of a mag net for the same purpose.

The oldest of devices of this kind (Fig 12) offered in 1570 by the Jesuit priest, Johannes Theisner, had a lodestone on a pillar, supposedly drawing iron balls up an incline When they reached the top they were to drop into a curved tube which would let them out at the bottom of the incline through a trap door The other three types are all based on what seems to have been the most popular notion of perpetual motion schemes, namely, on overbalancing one side of a wheel to make it rotate Stephan's plan (Fig. 14), dating back to 1789, was to have four cylindrical magnets sliding in holes bored radially into a square wooden block which was mounted so as to rotate between two pivoted magnets of opposite polarity All of these sliding magnets had their north poles pointing away from the center, hence they would be attracted by the pivoted magnet with the south pole at its free end, but repelled by the other Then the corners of the wooden block were supposed to tilt the magnets so as to carry the movement beyond the dead points

Instead of using such a wooden block, the writer in his high-school days proposed (Fig 15) a brass drum rotating close to a horseshoe magnet, with two rods running radially through the drum at right angles to each other Each of these rods was to carry heavy knobs at its outer ends and a soft iron armature inside the drum Then the magnet was to attract the armatures so as to draw out one knob after the other, leaving gravity to return them. Somewhat allied is the still more recent proposal of Korting and Hoepe (Fig 12) that a magnet be used to attract one after another of a series of soft iron pieces connected at their ends by brass links to form a ring and supported by rods which can slide in and out on the spokes of a wheel Of course none of these devices ever worked and some of our readers may be interested in figuring out why

Award of the Nobel Prize to Madame Curie

THE news has just been published of the award to Madame Curie of the Nobel prize for chemistry. This great woman scientist thus enjoys the extraordinary distinction of having twice been honored with this prize, for in 1903 one-half the award in the section of physics went to Pierre Curie and Madame Curie jointly, the other half being bestowed upon Prof. Becquerel. The material benefits conferred with the prize amount to the sum of $40,000, a gift which is not to be despised, although perhaps the principal value to the recipient lies in the great honor which attaches to this award, the list of the Nobel prize winners comprising, as it stands to-day, a perfect galaxy of the greatest genii in the scientific world of our time.

Printype
OLIVER
Typewriter

The Only Writing Machine in the World That Successfully TYPEWRITES PRINT

—17 Cents a Day!

The Printype Oliver Typewriter, which has crowded ten years of typewriter progress into the space of *months*, is now offered to the public for *17 cents a day!*

—Offered at the same price as an *ordinary* typewriter *payable in pennies!*

The commanding importance of *Printype* is everywhere conceded

For who does not see what it means to make the world's vast volume of typewritten matter *as readable as books and magazines!*

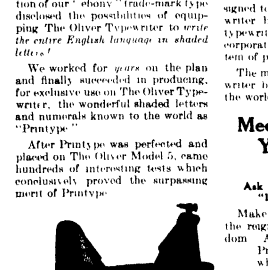
The Printype Oliver Typewriter is equipped with beautiful Book Type, such as is used on the world's *printing presses*

Printype illuminates the typewritten page with a marvelous clearness and beauty

It *does* away with all strain on eyesight which the old-style *outline* type imposes

Printype puts life and style and *character* into typewritten correspondence It makes every letter, every numeral, every character employed in business, financial, commercial and professional fields *"as plain as print"*

This complete story of *Printype* has never before been told Here it is



The Real Story of Printype

The idea from which "Printype" sprung resulted from the success of our type experts in equipping a typewriter used in our offices to write "The Oliver Typewriter" in our famous trademark type, just as the name appears on the outside of the machine and in all Oliver publicity.

The beautiful appearance and the marvelous clearness of the reproduction of our "ebony" trade-mark type disclosed the possibilities of equipping The Oliver Typewriter to *write the entire English language in shaded letters!*

We worked for *years* on the plan and finally succeeded in producing, for exclusive use on The Oliver Typewriter, the wonderful shaded letters and numerals known to the world as "Printype"

After Printype was perfected and placed on The Oliver Model 5, came hundreds of interesting tests which conclusively proved the surpassing merit of Printype

The Public's Verdict

The reception of Printype by the business public has been most enthusiastic We withheld any formal announcement until the machine had been on the market for some time. Personal demonstrations were its only advertising The resulting sales were stupendous Here, there and *everywhere*, Printype letters soon began to appear Wherever received, these distinctive, beautiful letters awakened immediate interest Thus the fame of Printype grows as its beauty and utility dawn on the business world

That the public is overwhelmingly in favor of Printype is impressively shown by this fact

Already over 75 per cent of our entire output of Oliver Typewriters are "Printypes"

Printype
OLIVER
Typewriter
The Standard Visible Writer

The public is *demanding* Printype

Within a year, at the present rate, *90 per cent of our total* sales will be "Printypes"

Thus The Oliver Typewriter, which first successfully introduced *visible writing* is again to the fore with another revolutionary improvement — *Printype, the type that prints print!*

To Corporations:

The Oliver Typewriter is used extensively by great concerns in all sections of the world

Our "17-Cents-a-Day" Plan is designed to help that large class of typewriter buyers who want the same typewriter that serves the great corporations, but prefer the easy system of purchase

The masses want The Oliver Typewriter because it stands the test of the world's largest corporations.

Meet "Printype"— You'll Like Its Looks

Ask for Specimen Letter and "17-Cents-a-Day" Plan!

Make the acquaintance of Printype, the reigning favorite of typewriterdom Ask for a letter written on the Printype Oliver Typewriter, which will introduce you to this beautiful new type We will also be pleased to forward the "17-Cents-a-Day" Plan on request

Address Sales Department,

The OLIVER Typewriter Company

AGENCIES EVERYWHERE

In the Bell Democracy

Membership in the telephone democracy of the Bell System means equal opportunity for every man, no matter who he is or where he is.

Each member of this Bell democracy has the same chance of communication, limited only by the distance the voice can be carried.

However remote, whether in the adobe house on the Rio Grande, on the Montana sheep ranch or in the isolated New England farm house, the Bell telephone is an open doorway to the Universal Bell System.

From each Bell outpost run lines that connect it with the central office—that nerve center of the local system.

Long distance and toll lines connect these nerve centers and furnish clear tracks for telephone talk throughout the land.

12,000,000 miles of wire are the highways over which 20,000,000 telephone talks are carried daily.

The Bell System binds together the social and business activities of a people in a shoulder-to-shoulder march of progress.

The period of American history which opened with the Spanish war will always be reckoned as one of the most momentous in the growth of the United States

As the immediate result of the Spanish war and our acquisition of Hawaii, the Philippines and Porto Rico, our Navy assumed an importance which it had never before held. The growth of our fleets since 1898 has been steady

During this period the Scientific American has lent its pages freely to the work of describing the growth of our Navy, and we believe that the intelligent interest in the Navy and its undoubted popularity have been due in no small degree to the efforts of this journal. As a fitting climax we are in a position to announce that on December 9th, we shall issue a magazine naval number, which will be written entirely by leading officials in the Navy, each of whom stands at the head of the particular branch of the service of which he treats.

The World Patent

To the Editor of SCIENTIFIC AMERICAN:

Your article in the issue of September 9th, 1911, on "The World Patent" is very interesting, and should pave the way to the realization of said object. A universal patent would be a great benefit to the industrial world, which you so cleverly photograph, and you as a leading scientific journal of this country should take up this subject and follow it with the same ardor and energy with which you are following the naval, aeronautical, and other important fields. Your devotion to this subject should influence activity in other quarters, resulting in the realization of said universal patent. The obstacles to the realization of said universal patent may appear great, but they can be easily removed by the concentrated efforts of the inventive or patent world and the countries forming the International Union. To this end I take the liberty to humbly offer a few suggestions. The effectiveness of a universal patent depends very much upon the support given to the matter by all the countries of the International Union as well as by many of the other countries not yet members of the union. To further make a universal patent effective, it must be issued at one predetermined place to the subjects of all the countries favoring such patent rights union. As most of the countries would desire to have some control over their patent business, the most effective plan may be to have universal patents issued by an international patent office, and working patents issued independently by each country, as will be seen hereafter. To insure the validity of a universal patent, a system of examination and record must be instituted at one predetermined place, whereby all the patents issued heretofore or to be issued by the countries of the union could be thoroughly traced and examined when necessary. For the above purposes an international patent office should be established at a predetermined place, where all patent applications are to be filed, examined, issued, contested, or adjudicated. Said international patent office can have within its system a judiciary board for the consideration of lawsuits connected with said patents. Said international patent office constituting a centralized industrial bureau, should have in every important branch of its service *attaches* from every country a party to the union. Within a predetermined length of time, each country forming a part of the union could have filed with said international patent office complete records of all the patent transactions of said country. The international patent office should issue a universal patent, representing certification of examination, for any invention found after due searching and examination to be entitled to same. Said universal patent in turn shall command the issue of a working patent (without any further examinations or objections of any kind) in each of the countries of the union in which application therefor be made, the two patents constituting the complete patent in each respective country. To defray the working expenses of said international patent office, a predetermined fee should be paid for each patent application. Such universal patents could be issued for twenty years, and could be made renewable for an additional number of years after the payment of additional taxes. A suitable tax should be paid to the country of which the applicant is a citizen, upon the issue of a working patent, and only half of such tax should be levied by each other country in which a working patent is secured. The validity, as to priority and patent rights, of a universal patent shall be absolute in all the union countries and subject to formulated laws, rules, regulations, and decisions of the patent office, but the working of a patent in any one country shall not be allowed before securing a working patent. For efficiency and uniformity, a language to be used for the international patent office transactions should be determined upon. Universal patent cases may be judged in any country of the union in which the case arose, but the decisions rendered should be subject to ratification by the board of justices of the international patent office, for which express purpose such board should be created. The above plan could be placed in working order within five years from its adoption, without interfering with the operations of the various existing patent offices. Since the United States issues the greatest number of patents, it is entitled to be designated as the home of the International Patent Office, second in choice being Great Britain or Germany. For a central location England or France may be preferred. An alternate plan would give the International Patent Office the power to issue a universal patent valid in all countries of the union without the additional working patent. Such plan, however, would be more difficult to realise at the present time, since it would centralize in the International Patent Office all the powers and authorities of record, examination, and guaranties also absolute justice, instead of having this International Patent Office as an examining department for all the union countries and as a composite board of record-based justice, as it is essentially intended to be.

Philadelphia, Pa.

Music a Palliative and Restorative in Cases of Nervous Prostration

To the Editor of SCIENTIFIC AMERICAN:

The readers of the SCIENTIFIC AMERICAN would doubtless be interested in a few incidents illustrative of the effect of music on the mentally sick. The Georgia Sanitarium for the insane has been making experiments along this line of thought. While the results thus far collated are not demonstrative nor conclusive, they are suggestive.

An instance of the palliative influence of music came under the writer's immediate observation. A patient with acute nostalgia (home sickness) on hearing a Stella grand piano music box, that was presented to the sanitarium for research work, immediately wrote home: "The nostalgia is gone. It is no longer acute home sickness with me. There is a Stella music box here that is health, happiness, heaven." A clergyman with chronic aphasia (inability to command words) on hearing the same instrument, summoning his will power in one supreme effort to speak, exclaimed, "That Stella is a star when it comes to music! I have been praying to die that I might go to Heaven, but Heaven is in that Stella music. Bless you, friends! What am I doing? I have lost my aphasia, the music of Heaven has given me my tongue again." A lawyer whose melancholia was complicated with acute nostalgia attended a number of musical entertainments that diverted his thoughts into new channels, and gave surcease to his imaginary troubles. Within thirty days he retrieved his former standing and was appointed a superior court judge.

The *rationale* or explanation of these marvelous results is apparent. The resuscitation or restoration of the will power by means of the emotions, or the addressing the will through the media of the emotions that make their appeal through music. The language *par eminence* of the emotions is music. Good music conduces to the restoration of the nervously prostrated by diverting the mind from brooding over imaginary troubles. By a soothing influence exerted upon the nerves, it calms the perturbed brain tissue, and acts as a stimulus, vivifying partially atrophied faculties, and inspiring hope, the hope that the melancholiac may yet accomplish some great achievement.

Owing to the fact that the State has all it can do to provide the absolute necessities of life for its three thousand insane, there is no appropriation for musical instruments. We are therefore under the necessity of laying these facts before the philanthropic with an invitation to cooperate with us in further research work. The State will pay express charges on small boxes marked "Georgia State Sanitarium Library." Large boxes containing orchestrions, phonographs, player-pianos, or other automatic musical instruments should have express prepaid and be addressed to the writer at the musical department of the State sanitarium. A large cathedral organ would facilitate the work of research. We are not averse to second-hand material.

The purpose of this journal is to record accurately simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

A Fatal Omission

IT is characteristic of the ineptitude which has lately characterized the handling of the subway situation that the present plans, which contemplate the expenditure of several hundred millions of dollars, make no adequate provision for connecting the subway system with the new Pennsylvania station in this city.

We remember that one of the most important sections of the exhibit of the Pennsylvania Railroad Company at the St Louis Exposition in 1904 was an unusually fine model of the then proposed North River tunnels and the great terminal station in the heart of Manhattan Island. The sectional model of the station showed at the easterly end of the building a four track subway, with easy approaches thereto from the arrival and departure platforms of the express and local trains of the company.

Now when the Pennsylvania Company embarked on the vast undertaking involving about one hundred million dollars expenditure, which has resulted in giving Manhattan Island direct steam railroad connections with the West and with Long Island, it was on the understanding that the city would build a subway down Seventh Avenue, and the company received every reasonable assurance that by the time their station was completed the city would be in a position to bring to the gates of its terminal and distribute the many millions of passengers, both suburban and long distance, that would have occasion to use the Pennsylvania system.

The Pennsylvania Company have 'made good'—the city has done nothing. Nay, not only has it failed to live up to a most urgent moral obligation, but in the plans for future subway extension, it has ignored the Pennsylvania terminal altogether.

The case is bad enough as regards the railroad company, but it is infinitely worse as regards the interests of the public, and when we say the public we have in mind not merely the residents of New York, but those of every city in the United States who may have reason to enter or leave New York over the lines of this company.

For the situation which confronts the traveller at the close of his journey to New York is both annoying and ridiculous. If he have any conception of the cost and importance of great engineering works (and every intelligent and informed citizen has this) he will realize, as his Pullman car sweeps through the great tunnels beneath the Hudson River and emerges in the noble station building that only a combination of the highest engineering ability and a far-sighted and wealthy management could have planned and carried out a work of this magnitude solely for the purpose of placing the passenger, with all possible expedition and comfort, in the very heart of the great city.

Having disembarked upon the incoming platforms, he naturally inquires which stairway or tunnel walk will take him to the platforms of the world-renowned New York city subway. To his astonishment and chagrin, he will discover that as far as rapid transit in the city itself is concerned, he has been deposited several city blocks from nowhere. After tramping down a cross street, he will find himself, with the majority of his fellow passengers, standing without shelter from wind or weather on a street curb awaiting the next car of a not-too-frequent service. Then, after something less than a mile of strap-hanging, our grip-encumbered passenger will reach the coveted subway.

"Verily," he will say to himself, 'this mountain in labor has brought forth a mouse."

This is the very anti-climax of transportation!

Nor is it sufficient answer to say that the traveller can take a "taxi." There are millions of passengers using the new Pennsylvania depot who cannot afford the "taxi," and must perforce make use of some five-cent fare system of transportation, such as the elevated or subway system. The objection is particularly strong when taxi rates stand at the present exorbitant figures.

What with plans and counter plans of rival transportation companies, of boards of estimate, of the Public Service Commission, and of individual city officials, this subway matter has gradually got itself into such a complicated "snarl," that we freely confess we long ago gave up as hopeless the attempt to keep in any intelligent touch with the situation. But of this much we are certain, that in failing to make any provision for running at least one of the subway lines through or by the new Pennsylvania terminus, the city has been guilty of the most serious blunder that it could have made.

We believe, however, that the case is not entirely hopeless, and that a way can yet be found to re-arrange the contemplated plans so as to enable travellers who wish to enter or leave New York city by way of the Thirty-third Street terminal to do so without the inconvenience, irritation and considerable loss in time which are incurred under the present conditions.

"The Last Word"

WE have received from a correspondent, who is a leading shipbuilder of this country, a clipping from one of the great London dailies, in which, under the caption of "The Last Word," its naval correspondent makes some rather startling comments on the gunnery trials of the English super-dreadnought "Orion"—the first ship to mount a battery of guns heavier than the 12-inch.

We gladly act on the suggestion, for the reason that the criticism made by this naval writer is based upon a popular error which we find to be very widely distributed. We refer to the suggestion, which amounts to a belief with a great many people, that the firing of the main battery of a warship—particularly of all the guns be fired together in a salvo—imposes such severe strain on the structure of the vessel as to weaken it even to the point of destruction. "The best brains in England," says the naval correspondent, "are perhaps unable to devise a structure capable of standing the terrific shock of ten 13·5-inch guns fired simultaneously."

Later, in the same article, this writer delivers himself as follows: "There is some reason to believe that there is truth in the theory advanced by some that, so far as our present knowledge goes, eight 12-inch, six 13·5-inch, or four 15-inch, represent the utmost broadside that we can build any ordinarily-sized ship to stand with certainty. Anything over this ratio, they say, is useful for paper comparison, and may possibly survive an action long enough to be of material service, but the time dismally prophesied in the past, when naval warfare would not mean a ship resisting the blows of the enemy so much as surviving her own gunfire, seems (possibly) near at hand."

It may be stated once and for all that this "bugaboo" of the harmful effects of the firing of a ship's heavy guns upon the ship itself is without the slightest foundation of fact. Indeed, the stresses set up in the ship as a whole by the recoil of its batteries are almost insignificant compared with those which result from the action of the sea in heavy weather.

The writer remembers how, when the "Lusitania" was being driven at 25 knots into a heavy Atlantic gale, the two ship joints where the upper deck structures had been cut through to allow for the longitudinal bending of the ship as she rode over the waves, showed a movement of fully one inch. Rough calculations showed that the deflection of the ship, considered as a beam, must have amounted to twelve or fifteen inches. Now our battleships have reached a length of between five and six hundred feet. Their decks are not cut as are those of the Atlantic liners, and it will be realized that when they come to be driven hard into a head sea, carrying, as they do, the heavy concentrated loads of the turrets, they will be subjected to stresses of an extremely heavy character.

But all of these conditions are well known to the naval constructor, and the working out of the stresses due to firing the heavy guns forms only a part of the many calculations which he makes in proportioning the different parts of a ship's structure. The energy of the recoil of a 12-inch gun is accurately known. It is transmitted from the trunnions through the girders of the gun carriage to the turntable, and from the turntable through the barbette structure to the framing and plating of the ship. All of this structural material is given such extra strength as may be necessary to take care of these recoil stresses.

During his recent stay with the Atlantic fleet, the writer took occasion, on board the "North Dakota," to go through such portions of the ship as would be most affected by the recoil and examine the paint for those cracks which in a ship are the earliest evidences of straining of the structure. This he did both after the heavy gun practice by day and practice with the 5-inch secondary battery by night, and in neither case was there the slightest sign that the structure of the ship had been affected. The ships of our navy can fire their whole broadside just as long as the ammunition supply holds out and with never a thought as to its effect upon the ship itself.

Hobbs' Theory of Continental Glaciers

AN ingenious hypothesis in regard to the history of continental glaciers and their relation to atmospheric phenomena has been worked out by Prof. W. H. Hobbs.

There are at present two of these glaciers, one of which covers Greenland and the other Antarctica. These great ice sheets differ in many important particulars from the mountain glaciers of lower latitudes. In the latter the land surface always projects above the highest levels of the ice and snow, the glaciers occupying only the hollows and troughs of the mountain slopes. The continental glacier, on the other hand, blankets practically the entire rock surface, except at the margins forming a flat dome; its model is independent of its basement, and its movement is independent of the grades of the underlying floor.

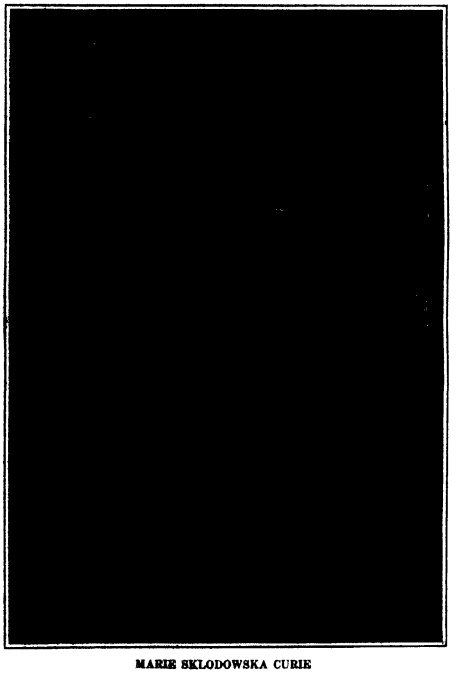
A peculiar system of winds prevails over each of the polar ice caps, in which the distribution of barometric pressure appears to play no part. The winds blow radially outward from the center of the polar continents, i. e., they flow down the ice slopes, often with great violence. Usually of sufficient strength to lift the dry granules of snow a couple of feet or more in the air, when the wind develops greater strength the drifting snow rises to the height of a man, and during the characteristic polar blizzards is probably carried to heights of 100 feet or more above the ice surface; yet the direction is always and invariably outward from the center of the dome. On the other hand, the upper air currents, as shown, for example, by the drift of smoke from the volcano Erebus, in the Antarctic, and by the movement of cirrus clouds, are in the opposite direction, i. e., toward the interior of the continent. Normally drifting from the northwest, when the outward flow of surface air assumes great violence the smoke of Erebus swings around and moves directly south, with an accelerated velocity, as if the upper air was being drawn strongly inward to replace outward movement in lower levels.

These wind systems are explained as follows: Each of the great ice sheets cools the air in contact with it, and the cold and heavy air drains down the slopes of the polar continent. The upper air is drawn down in the central vortex to replace it. Thus air comes from a region charged with ice particles, i. e., from the level of the cirrus clouds. The descending air warms adiabatically, according to a well-known law; its ice content is melted and vaporized, only to be condensed again when the cold surface of the glacier is approached. Thus the glacier is fed entirely by the moisture of the upper air. This is the opposite of the process that occurs in the case of mountain glaciers. In the latter the surface winds blowing up the slopes are adiabatically cooled, and the glacier is fed by the moisture which they discharge.

The fine dry snow deposited over the interior of the continental glacier is continually swept down the slopes, forming the rounded, dome-like surface.

According to this view, the old theory of two polar anticyclones must give place to that of two continental (glacier) anticyclones, the centers of which—the wind poles of the earth—are not coincident with the geographic poles.

In Pleistocene times the vastly larger ice sheets must have given rise to correspondingly vaster permanent anticyclones. Direct evidence of a Pleistocene anticyclone has been obtained by Prof. Solger of Berlin, who in studying the fossil sand dunes of the North German plain, has shown that the prevailing winds at that time came, not from the west, as they do to-day, but from the east.



Marie Sklodowska Curie

The Greatest Woman Scientist, Twice Recipient of the Nobel Prize

FEMINISM very nearly won a great victory in the French Academy of Sciences on January 23rd, 1911, when, in the election of a successor to the deceased academician Gernez, Marie Sklodowska Curie was defeated by two votes. At a joint meeting of the five academies which compose the Institut de France, a majority had opposed the admission of women, as contrary to tradition, but each academy was left to decide the question for itself.

The Academy of Fine Arts had a few women members long ago but the Academy of Sciences has never admitted a woman. It was, perhaps, the opposition of the anti-feminists that induced Mme. Curie to apply as a candidate for the chair in the section of physics left vacant by Gernez, and formerly occupied by her husband and collaborator, Pierre Curie. In the preliminary grading of candidates Mme. Curie was placed alone, in the first grade, while her competitors, five eminent men of science, were assigned to the second grade. Mme. Curie, however, received only 28 of the 65 votes (the Academy consists of 66 members), while 30 votes were cast for Edouard Branly. There were good reasons for this choice, entirely apart from considerations of sex. Branly is a physicist of world-wide celebrity who, unlike Mme. Curie, has received few honors and emoluments. He invented the coherer for the detection of electric waves and to him Marconi's first wireless message was addressed. Many of the academicians naturally desired to recognize the very important part played by their compatriot in the development of wireless telegraphy. Moreover, Branly is sixty-four years old and this was his third candidacy, while Mme. Curie is only forty-three and had never before applied for admission. It is not customary to admit a candidate on the first application, and Mme. Curie's chance of living until the next vacancy shall occur is greater than Branly's.

Who is this remarkable woman who so nearly surmounted these formidable obstacles? The dry and formal account of herself and her work which she submitted with her application, according to custom, is perhaps more eloquent than an exhaustive biography. Marie Sklodowska was born in Warsaw November 7th, 1867. She became a student in the University of Paris where she attained the degrees of licentiate in physics in 1893 and licentiate in mathematics in 1894. In 1896 she received a certificate of fitness for the secondary instruction of girls, and in 1900 became lecturer in physics in the Ecole normale supérieure for girls in Sèvres. In 1903 she received the degree of doctor of physical science, in 1906 she became lecturer in general physics in the University of Paris, and in 1909 she was promoted to the professorship of general physics, as successor to her lately deceased husband, Prof. Pierre Curie, to whom she was married in 1895.

MARIE SKLODOWSKA CURIE

Immortalized by her researches on radium.

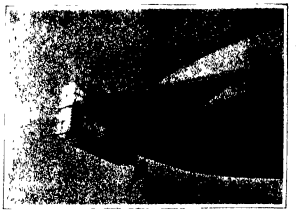
She is an honorary or foreign member of the Royal Institution of Great Britain, the London Chemical Society, the American Philosophical Society, the American Chemical Society, the Imperial Academy of Sciences in St. Petersburg, the Royal Swedish Academy and other learned bodies, and has received the honorary title of Doctor from the universities of Geneva and Edinburgh. In 1898 Mme. Curie, then thirty-one years of age, received the Gegner prize from the French Academy of Sciences, nominally for her extensive researches relating to the magnetic properties of iron and steel, although the report of the awarding committee also alludes, in terms of the highest commendation, to the researches in radio-activity which she had already begun, in co-operation with her husband, and to their recent discovery of the radio-active element which Mme. Curie named Polonium, in honor of her native country.

The Gegner prize was awarded to Mme. Curie again in 1900, and a third time in 1902, together with the Berthelot medal. In 1903 the Nobel prize for physical sciences was awarded, half to Mons. and Mme. Curie and half to Henri Becquerel, whose discovery of the spontaneous radio-activity of uranium ore formed the basis of all subsequent researches in radio-activity. Only a few days ago we heard the news that Mme. Curie has been honored with the Nobel prize a second time, on this occasion in the division of chemistry. The list of medals and prizes which have been awarded to Mme. Curie in foreign countries is too long to quote.

In addition to the numerous researches in radio-activity which she made in collaboration with her husband, Mme. Curie has published a great many independent papers, and a volume, "Investigations of Radio-active Substances," in which the results of their co-operative researches, including the epoch-making discovery of radium, are set forth.

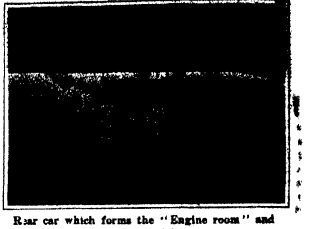
Radium and polonium are not the only fruits of this ideal marriage, which was blessed by the birth of two children who already give evidence of inheriting the genius of their parents. After the shocking and untimely death of Pierre Curie, who was killed by a truck on a Paris bridge, in 1906, at the age of fifty-seven, a large majority of his colleagues recommended to the ministry of public instruction the appointment of his widow and coadjutor as his successor. The result is that this gifted woman, the only one of her sex who has ever received this high honor, is now a full professor in the venerable Sorbonne.

All who have seen Mme. Curie at work in her laboratory, or have listened to her lectures, have been impressed by her undemonstrative zeal, her abstraction from external disturbances and her aversion to sensational effects.



The early life of Marie Sklodowska Curie is less well-known to the general public than the later phase, in which she has become famous. And yet there is a peculiar romantic, and indeed pathetic interest attached to the incidents of her youth. Her father was a distinguished physicist, and professor of chemistry at Warsaw, Poland. Her mother died when the child was yet quite young. Marie grew up in her father's laboratory, imbibing the spirit of scientific research, and acquiring that sureness of eye and skill of hand which is so indispensable to the worker in experimental science. It is no doubt largely to her very early initiation into the technique of laboratory work that her extraordinary ability in this direction must be ascribed. Marie's apprenticeship was, however, brought to a rather early close by the pressure of necessity. As the daughter of an impecunious college professor, the eighteen-year-old girl set out to earn her own living as governess to the daughters of a Russian nobleman. But Providence had destined her for another fate. In one of those agitations which have been so common in the history of Russia, a patriotic society of students at Warsaw was brought under the scrutiny of the ever-suspicious government, and for fear of being compelled to testify against some of her father's pupils, Marie migrated from her home country and took up her abode in Paris. There she lived for a time a life of the utmost privation. Her repeated efforts to obtain employment in one of the laboratories seemed to avail her nothing. Finally she was allowed to perform some of the trivial offices in connection with the preparation of laboratory experiments. And once this meager foothold was gained, it was but a matter of days before the extraordinary faculties of the new assistant had attracted the attention and caused the amazement of the head of the department, Prof. Lippmann. The eminent scientist befriended the girl, and incidentally also introduced her to one of his most promising pupils, Pierre Curie, with whom she became associated in research, and later, in the bonds of wedlock. It was she who fanned to new endeavor the flagging spirits of her husband, in those moments of discouragement which are apt to come to all engaged in intense scientific research. And together they gained the undying trophies of fame when, with the isolation of radium salts the name of Curie suddenly rose to international renown. And then, not many years later fell that terrible blow, separating the two who together had faced the hardships of everyday life, and in strangely perfect union had toiled, against much discouragement to reap the precious harvest of scientific research. While crossing the street Prof. Curie tripped and fell, and was instantly killed by a passing truck. Thus in an evil hour France was bereft of one of her greatest physicists, the world of a genius and Madame Curie of her life companion and husband. Her composure, upon receiving the terrible news, is commented upon by the *Gaulois* "Nothing could have been more characteristic of the wonderful Madame Curie, than the coolness with which she received the news of her bereavement. There were no tears, no traces of grief. Over and over she repeated 'Pierre is dead!'" One feels that here perhaps the Frenchman, with his demonstrative temperament, somewhat misjudges this great woman. The deepest emotions are not always those that can find their vent through the common channels of physical expression. To us there seems something infinitely pathetic in the monotonous repetition of that simple and sad formula, as the mind that with the insight of a genius has successfully grappled with some of the most abstruse problems presented to the science of to-day in the realm of inanimate matter, is brought face to face with the great problem of life and death. Here all men are on a level and impartially fate has dealt to this great genius as to us all life's share of human sorrow. Yet with unbroken spirit, and with renewed devotion she turns to continue now in loneliness, her great life work, her priceless gift to humanity.

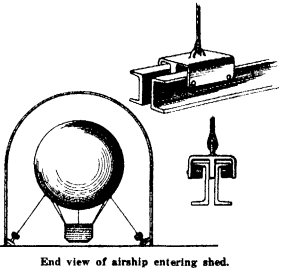
One can not help reflecting on the retribution dealt by fate to the Eastern monarchy—that makes life unendurable to the scholar of independent thought—in taking from her the woman who would have added the brightest laurel to Russia's wreath of scientific attainment.



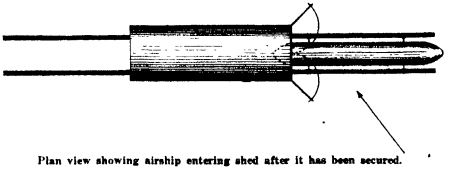
Zeppelin's Schwaben

A High Speed Craft for Passenger Service

By Carl Dienstbach



Sharply pointed stern with "tail" and rudders like those of an aeroplane.



Rear car which forms the "Engine room" and holds two powerful motors.

IT is only recently that the true significance of the great dirigible dockyards in Friedrichshafen became apparent. From the early summer of 1910, till the spring of 1911, no new airship left the stocks, and when finally a second "Deutschland" put in an appearance, she looked like a mere reconstruction, showing neither greater speed nor better maneuvering qualities than the first "Deutschland," which had been shipwrecked the year before. Still there was progress in a less conspicuous but very important direction. The first "Deutschland" had come to grief because under very adverse conditions and with a motor failing at the most critical moment, she could not be kept afloat, and gradually settled into the pine trees covering the crest of the Teutoburger Wald mountains which she had to cross at that time. To strengthen the new "Deutschland's" floating power in any similar emergency, her hull was built lighter, permitting her to carry more ballast for the same number of passengers. In addition a special test was made over Lake Constance, to show the exact amount of the lifting and depressing effect that could be obtained from her propellers and rudders alone. It was found that with only two motors and two propellers in action, the new ship could be raised by power like an aeroplane, from a static level of equilibrium at an elevation of 2,132 feet to 4,756 feet. This represents a purely dynamic lift of considerably more than two tons (4,400 pounds). With three motors and four propellers the ship rose further from 4,756 feet to 5,904 feet, adding nearly another ton (1,980 pounds) of dynamic lift. It remained for some time at this level, carrying four passengers, its regular crew of nine, 242 pounds of fuel and oil, and more than two tons (4,400 pounds) of ballast. If one-half of this ballast had now been shed an elevation of 7,514 feet could have been reached, while still carrying over one ton (2,200 pounds) of ballast. This proves an astonishing reserve of floating power for the arrow-like Zeppelin balloons. If their motors remain intact and they are not overloaded with passengers. What it means in warfare is shown by a simple consideration. In spite of their bulk, they are safe from artillery fire at such high levels. Their diameter is hardly greater than the wing spread of a Wright aeroplane which at the same height appears as a mere speck in the sky, and a Zeppelin at this level look like a match, its lean shape making it a poor target. In the thin air its own speed increases, going with the strong winds of these high levels, even the slow "Deutschland" will easily surpass 60 miles an hour, making her entirely immune. Bomb dropping from aircraft becomes efficient in every respect in exact proportion to the weight of the bomb. A torpedo containing one ton of dynamite dropped from the "Deutschland" from an altitude of 8,000 feet, could be aimed with all the certainty of a shell. Air currents (and air resistance) have so little influence on this great mass that its flight through the air would be determined solely by the speed of the ship over the ground and by its altitude both easily ascertained. Considering that a mere turn of the rudders will instantly deprive the ship of a lift of three tons, it is seen that the sudden dropping of a ton of ballast has no influence whatever on the stability of its flight. It seems odd that to-day the French depend so much on a costly chain of fortresses, which might be very efficient in preventing any repetition of the sudden victorious dash of the Germans in 1870, if the tedious hauling of heavy ordnance and building of entrenched batteries were the only means of reducing them, when in the Zeppelins the Germans now possess an instrument so efficient to bombard the "key fort" without any preparation or risk, and on the sole condition of fairly good and clear weather.

NEW RIGID ZEPPELIN AIRSHIP.

Although the new "Deutschland" had been amply insured against any conditions such as destroyed the first, it was soon to fall a victim to an odd and unforeseen accident—a collision with its own shed. Trivial mishaps from lack of experience unfortunately involve a great loss of money and prestige if they happen to a large and costly dirigible instead of an inexpensive aeroplane. But in this case vindication was not long delayed. The new passenger ship "Schwaben" was almost completed when the "Deutschland" broke in two. It was a little smaller, displacing 634,500 cubic feet, instead of the "Deutschland's" 667,560; 462 feet long instead of 499 for the same beam of 46, and with 17 gas cells instead of 18. In spite of this handicap it showed a speed of a fraction less than 43 miles an hour in the trial trips, measured exactly by running in calm air many times in both directions, over a piece of straight railroad track of known length. As this speed exceeds that of most biplanes, and principally that of the representative Wright aeroplane, it revolutionizes all former ideas about the dirigible and its inferiority to the aeroplane. As a matter of fact the "Schwaben" won in a race with a Euler biplane, from Darmstadt to Frankfurt. With only two of her three motors running, it still broke all previous dirigible records, at 38 miles an hour. The great improvements in Zeppelin's ships, of which the "Schwaben" was the first brilliant exponent, concern first of all the motors. There is nothing on which the safety and success of a rigid airship depend so much as on the reliability and power of its engines. This lesson had been so well learned in Friedrichshafen that the Zeppelin factory finally undertook to design its own motors. Mr. Maybach, one of their engineers, set to work improving the standard Daimler motor, which drove the earlier ships. He increased the number of cylinders from 4 to 6 and the horse-power from 110 to 165. The reliability also was so improved that the "Schwaben's" engines have never given trouble in over a hundred passenger trips, some of which were 700 miles long. Many experiments had also been made to better the shape of the hull. The difference between the "Deutschland's" conical bow and the egg-shaped bow of the "Schwaben" is striking. To diminish friction the outer envelope of the "Schwaben" was stretched very carefully over the frame, so it is so smooth and firm that non-technical observers have compared the "Schwaben's" "solid" hull to that of a warship, on account of its "gray" color. To further cut down head resistance, the three

Pumping Gold Bullion from the Sea

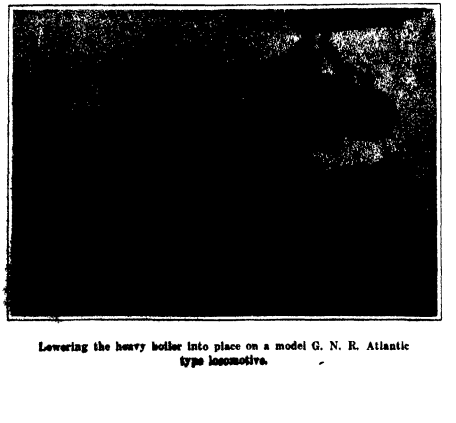
Recent Efforts to Salve the "Lutine's" Treasure

DURING the past summer season efforts were renewed to recover more treasure from the wreck of the old British frigate "Lutine." This waterlogged hulk has been a fascinating speculation for a good many years, and the alluring part of the project lies in the fact that no one knows just how much specie and bullion the ship carried when lost. What is known, however, is that something like half a million dollars worth of gold and silver bars and coins have been reclaimed in the course of the past century There is every reason for the belief that the frigate had many times this treasure on board when she sailed from England on the 9th of October, 1799, and this belief has inspired the efforts made from time to time to bring to the surface the buried riches

In the last years of the eighteenth century, plodding Hamburg awoke one morning, so to speak, to find herself the principal commercial port of northern Europe, and this sudden prominence came when she was financially unprepared to meet the exigencies of trade Her bankers were unable to provide the funds for the prompt honoring of bills of lading, and exchange involved a discount of even as much as thirty per cent. Business could not be pushed at this rate without a ruinous loss, and the merchants of London, with the assistance of British bankers determined to relieve the stress by shipping funds to the German port At first, it was intended to send the money in a merchant craft suitably convoyed by an armed ship, but news of this relief movement rapidly spread among the London traders and it was finally decided to dispatch the gold and silver in a man-of-war because of the amount involved It was believed that in this way the menace of the French cruisers could best be avoided and the treasure more speedily and safely delivered in Hamburg Accordingly, Admiral Duncan, then commanding the British North Sea fleet, detailed the frigate "Lutine"—a ship captured from the French some years before—for this service. The "Lutine" was loaded with her precious cargo secretly in order that the enemy across the Channel should not know of her mission This secretiveness has been principally responsible for a large measure of the uncertainty which has since existed in regard to the quantity of bullion and specie dispatched On the 9th of October, 1799, the "Lutine" sailed from Yarmouth Roads and headed north for Hamburg in the teeth of a heavy wind By the time the ship reached the North Sea the wind had grown into a gale blowing directly toward the Dutch coast In the gloom of that fateful night and under the pressure of the wind and the treacherous sweep of the North Sea currents, the "Lutine" struck the Dutch coast near the entrance to the Zuyder Zee It is quite probable that none of her officers knew of her danger She hit the sands at full speed, and immediately was thrown over on her beam's end. At the time, she carried quite three hundred persons aboard, but so sudden was the disaster that but two of this total number survived

The morning after the "Lutine" struck, the ship had substantially disappeared from above water save for the wreckage which littered the beaches of the near-by islands of Terschelling and Vlieland There was no one to tell how the ship happened to be out of her course nor anything as to the extent of her precious cargo At that time, the Dutch government was an ally of France, and claimed the wreck as spoils of war so that it was quite impossible for the British to do anything toward salving the sunken property Without going into the history of the matter, the specie aboard the frigate and most of the gold and silver bars had been insured at Lloyds' of London, and those underwriters promptly paid up A year or two after the "Lutine" went ashore, the King of Holland gave official sanction to salvage operations upon the wreck At that time, the hulk was not embedded in the sand and it was easy to reach it at low tide The work was pursued by guarded fishermen using oyster tongs and other primitive implements However, despite these handicaps, the government recovered treasure to the value of nearly $280,000 The sea did not intend to give up her riches readily, and toward the end of 1801 the wreck was completely buried by a bank of sand, which put an effectual stop to further salvage operations by means of the facilities then available It was not until 1814 that efforts were renewed to recover the remaining treasure, but the undertaking was unsuccessful In 1821, a company, known officially as The Decretal Salvors obtained a royal concession from Holland upon the understanding that fifty per cent of the value of what ever should be salved should be paid to the Dutch government This enterprise was composed of Netherlanders, and is still in existence In 1822, the British underwriters, stirred by the efforts of the Dutch company, appealed through diplomatic channels to the King of Holland The latter, to show his friendly regard for the King of England, donated his interest in the wreck to King George IV, who, in turn, made over this gift to Lloyds' committee as a part indemnification for the loss that Association had suffered in the wrecking of the "Lutine" This point is of present concern because all salvage operations, since 1823, by British subjects, have been authorized by Lloyds' of London and, to that extent, backed by that Association The Decretal Salvors still have their right in fifty per cent of the values recovered

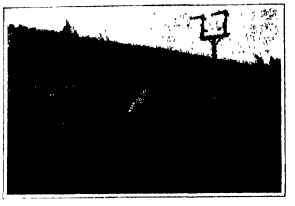
In 1857, the swirling currents at the entrance to the Zuyder Zee swept the hulk clear of sand, and at once salvage operations were renewed diving dress being employed for the first time in the undertaking It was not until the following year, however, that any substantial results were obtained By the middle of October, 1858, gold and silver bars and specie were brought to the surface amounting to a value of $140,000 It did look as though the buried riches were surely to be reclaimed, but the North Sea decided otherwise, and once more hid the hulk under a heavy blanket of sand The Decretal Salvors stuck to the task from year to year with varying results and by the end of 1860 they had to their accumulated credit a total recovery of $220,000 worth of treasure The bulk of this was found around the stern of the wreck and within an area sheltered by the ship's rudder which was still in position The salvors remained passive until 1867, and between that time and 1886, the results were too meager to pay for the labor involved In 1886, steam, suction, shell-dredgers were engaged in the work for the first time It was believed that it would be possible in that way to remove the overlying sand which had increased in depth over the hulk Work in this way was pursued for the next three years yielding various coins to the combined value of $4,600 The shell dredgers were operated each season for the following four years but none of the treasure was brought to the surface The various other efforts made since 1892 and until the National Salvage Association took over the task during the present year have been without result



The present salvors have attacked the problem from a new point Heretofore, all of the money and bullion reclaimed has been found lying outside of the contour of the stern of the wreck and on the side upon which the hulk rested The National Salvage Association believe the bulk of the gold and silver to have been stowed amidships in the shot lockers adjacent to the main cable-room—the cannon balls being piled on top of the treasure It is hard to understand what foundation exists for this opinion As the midships section in Fig 2 shows, the cable-room and shot lockers occupy a large space freely open to the crew by reason of the exigencies of service, and it is difficult to justify the placing of such riches in an exposed place of this sort On the other hand the after magazine of those old frigates was a carefully guarded room and either that compartment or one of the divisions lying in the same after section would have been the likeliest place to hold valuables that called for continual surveillance The fact that all of the gold and silver bars and most of the coins so far recovered have been found buried in the sand about the stern bears out the belief that the treasure was housed in the magazine or nearby

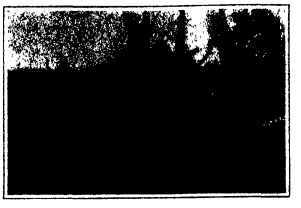
Garden Railways

Elaborate Toys and Serviceable Miniatures on English Estates

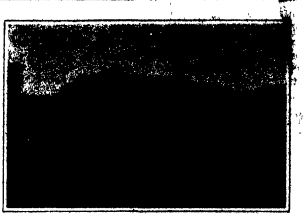


By Percy Collins

GARDEN railways are now quite the vogue in England and their popularity is extending to other countries The diminutive rolling stock and permanent way fall naturally into two groups, viz., those which are too small to be regarded as anything but elaborate toys, and those which possess sufficient power and stability to accommodate passengers and freight. An important event in the history of garden railway engineering was the standardization of gages. Now-a-days model railway work is based upon recognized standards which cannot be altered. There are four small gages, ranging from 1½ inches to 2½ inches, and six large gages ranging from 3½ inches to 15 inches. Models produced by leading firms accommodate themselves to one or other of these gages, while amateur workers, for their own convenience, adhere strictly to the same standards. In each gage a multiplicity of accessories made to scale, such as stations, signal-boxes, bridges and level crossings, are obtainable. The smallest



Lowering the heavy boiler into place on a model G. N. R. Atlantic type locomotive.



gages of all are specially suitable for indoor work but the 2½ and 2½ inch gages are both popular where outdoor railways are concerned each having its own circle of votaries Several elaborate systems in the latter gage already exist, the most notable being the "Great Holmwood Railway" at Thorp, Norwich, the property of Col J R Harvey, by whose courtesy we are able to reproduce the accompanying photographs A brief description of this system will give the reader an idea of the possibilities for pleasurable occupation which a garden railway offers The main line is a continuous single track, 750 feet long which passes round a loop The permanent way is laid on a brick foundation about three feet from the gravel walk, in order to obviate the necessity for stooping when attending to the models. The curves are all 24 feet radius, and there are gradients of 1 in 40, 1 in 60 and 1 in 70 the remainder of the line being level Including sidings, there are some 600 feet of track the laying of which necessitated the

A 15-inch gage locomotive on the Rhyl miniature railway.

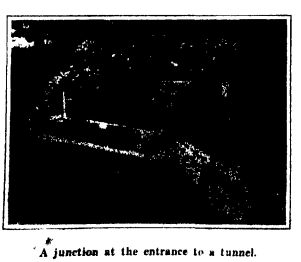
Getting ready for the day's work.

use of 7,200 chairs and 10,800 brass screws There are three through loops, eight sidings, four principal stations, three bridges, two tunnels, an engine-shed and turntable, and seven running sheds, five being 18 feet long and two 8 feet long There are two pits for lifting up one having the rails hinged to drop for convenience in getting at the burners of the locomotives also a tank with distilled water supply, and a complete system of signals, points, and footlights A "third rail" has been laid down over the entire system, so that the whole line is available for electric traction The permanent way was ballasted with "blue billy" obtained from the local gas works—a wise precaution against the growth of weeds All the bridges which span the garden paths are so constructed that they may easily be lifted up The steam locomotives of the "Great Holmwood Railway" comprise a four-wheel coupled outside cylinder bogie tender engine, a four wheel coupled bogie ten wheel tank-engine with outside cylinders, a four wheel coupled inside cylinder tank-engine and a four wheel shunting engine The electric models comprise a tube locomotive fitted with a special design of motor by Messrs Marshall & Wood, a four-wheel coupled tank engine fitted with an Avery motor, and a Great Northern Railway single express engine equipped with a motor in the tender as well as in the engine

The rolling stock includes some forty odd vehicles ranging from a platelayers' trolley to a mail coach and sleeping and dining saloons There are open trucks, closed trucks, crane trucks, tipping contractors' wagons, goods and passenger "brakes," with types of various other vehicles all being fitted with central buffers, which are never found to interlock when the train is passing round curves A speed of eight miles an hour has been attained on a measured length of this railway while the locomotives are capable of pulling with ease a train of thirteen coaches

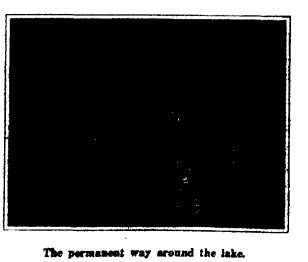
Another noteworthy railway is the property of Mr G S Mitchell of Sheffield It has a gage of 7¼ inches, while the "inner circle" is laid also with a 3½ inch gage track to accommodate the owner's smaller models. The length of the main line is 439 feet, of the inner line 330 feet, while there is also a connecting line of 62 feet and an engine-shed line of 110 feet Upon leaving the shed, the locomotive passes down a steep gradient into a cutting four feet deep, from which over 100 cartloads of earth were removed It then enters the 54-yard long tunnel, which is the chief engineering feature of the line built, as it is, of brick throughout, on proper drums, with 14 inch side-walls and arch bricks for roof The tunnel is properly drained, and the bank through which it passes consists of about 200 tons of earth The line emerges near "South Junction," the branch for the "inner circle," which passes round an ornamental lake A very perfect system of signalling has been instituted Sixteen signals are in use, and all of them are duly lighted when the line is used after dark There is a properly-equipped signal-box, and by obeying the ordinary laws of signalling and by codes of flag-signals—red and green lamps at night—and engine whistles the safe control of the line may be achieved without the interchange of a word between driver and signalman Mr Mitchell's locomotives comprise a 3½-inch gage tank-engine, a 3½ inch gage Great Northern Railway model, also a

A 2-inch scale 9½-inch G. N. R. locomotive, shown in process of construction on the previous page.



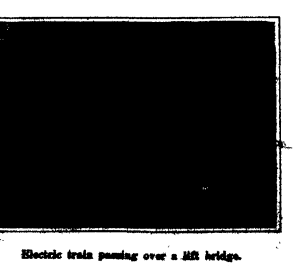
7¼ inch gage "Precursor" locomotive, built from designs by Mr Greenly All the engines are fired with a mixture of three parts coke and one part anthracite coal The rolling-stock includes a large double bogie wagon and a ballast truck, as well as a 3½-inch gage driving truck, with water and coal space, for use with the small locomotives

A few enthusiasts, with the necessary space and cash at their disposal favor the 9½-inch gage, with models made to a scale of 2 inches to the foot, that is, one-sixth full size A photograph showing such an engine undergoing its "works test" is here reproduced. It is a scale model of the Great Northern Railway "Atlantic" locomotive No 1442, which hauls the Royal train When in full working trim, the model—the boiler of which is made of copper throughout, and fired with ordinary coal—weighs 950 pounds. In favorable circumstances it will pull a load of two tons, and travel at a speed of seventeen miles an hour It may interest the reader to know that the cost of such a model, capable of pulling himself and his friends in specially-designed passenger trucks, would be about £300.



The so-called light railways, with a gage of 15 inches, accommodate models built to a scale of three inches to the foot. When space permits, and when the additional cost is not a barrier, this gage will certainly be found to constitute, in practice, the ideal for a garden railway This was the gage employed by Sir Percival Heywood when he constructed the famous "baby" railway on the Duke of Westminster's estate, at Eaton Hall in Cheshire. Roughly speaking the line cost about $6,500 per mile to construct, exclusive of the various buildings and other paraphernalia. It connects Eaton Hall with Balderton Siding, on the Great Western main line, some four and a half miles distant, and is almost exclusively used for freight, though the rolling-stock includes one passenger coach—an eight-wheeled carriage capable of accommodating sixteen persons—in which visitors to the Hall, including Royalty, occasionally travel The trains on this railway carry, on an average, some 6,000 tons each year, and travel from 4,000 to 5,000 miles

The original locomotive of the Eaton Hall Railway is known as "Katie." Her cost was £400, and she was designed and constructed by Sir Percival Heywood More recently a locomotive of the "Atlantic" type, appropriately called the "Little Giant," was tried on the line This engine was constructed by Messrs Bassett-Lowke, and proved capable of hauling 12 tons on a level at four miles per hour, and five tons at 15 miles per hour up gradients of 1 in 100. With 2½ tons behind it on a falling gradient, it attained the enormous speed of 26½ miles per hour, equal to a scale speed of more than 100 miles per hour In matters of detail, this engine and its duplicates represent the high-water mark of model engineering



The Eaton Hall Railway is not, of course, required to prove itself financially profitable, but the 15-inch gage is being exploited commercially at the present time. In November, 1904, a limited company, styled the Miniature Railways of Great Britain, was formed to operate tiny passenger systems. The first of these railways was built on the south shore at Blackpool It met with immediate success, and has since been followed by similar railways in Sutton Coldfield Park,

A junction at the entrance to a tunnel.

The permanent way around the lake.

Electric train passing over a lift bridge.

GARDEN RAILWAYS

...Birmingham, the International Exhibition at Turin, in France, and the Shepherd's Bush Exhibition in London. More recently the company has laid down miniature railways in the Zoological Gardens and Park near Halifax, and in the grounds of the International Exhibition at Brussels. Among other notable garden railways is that laid down by the Rev. J. E. Preston in his vicarage garden at Ballantown, Drogheda, Ireland. Mr. Preston has made with his own hands the sleepers, locomotives, carriages, points, and signals. He also prints and issues his own tickets.

The gage of the railway is 1 foot 9 inches, and consists of about five tons of rails, 14 pounds to the yard. Though "miniature," it is large enough to carry its constructor and his friends round the grounds.

Apart from the successes which these miniature railways have scored at pleasure resorts, no reasonable doubt can be entertained that, where land is available, they would prove equally profitable for the conveyance of passengers and goods from railway stations to outlying districts. Permanent way materials, which include steel rails—weighing 12 pounds to the yard—fixed to steel corrugated sleepers by tips and dogs, all necessary fish-plates, bolts, nuts, etc., including bending, and four sets of switches, would cost in the neighborhood of $1,800 per mile. To this must be added the cost of construction which would vary according to the nature of the land over which the railway was laid. The approximate cost of an "Atlantic" type locomotive would be about $1,600.

It remains to be said that the photographs reproduced on these pages give a genuine idea of the power possessed by these diminutive locomotives.

Science

Disastrous Typhoon in Formosa.—Consular reports state that the worst typhoon experienced in Formosa for fifteen years swept over the island on August 31st. In the city of Taihoku, alone, over 2,000 houses were completely wrecked, fifty-eight people were killed outright, and twenty-nine others lost their lives in a railway bridge accident. The sugar-cane crop of the island was injured to the extent of 20 per cent, and the rice crop 15 per cent.

Ventilation as a Protection Against Frost.—To the long list of the means heretofore proposed of protecting fields, orchards and vineyards against frost a new one has recently been added by M. F. Chavernac. Writing in *Progrès agricole et viticole*, he points out the fact that frosts are not feared when the wind blows; he is thus led to suggest the creation of an artificial wind by the installation of electric fans among the plants to be protected. He considers this plan applicable chiefly to vineyards, but also possibly useful in orchards.

Sugar from the Nipa Tree.—According to Dr. H. D. Gibbs, of the Philippine Bureau of Science, the nipa tree—already so useful to the Philippines and the East Indies generally as a source of thatching, matting, cigarette wrappers, toddy, and an edible fruit—promises to revolutionize the sugar industry of the islands, as its sap yields a sugar of superior quality. Samples tested in his laboratory polarized at 98.8 per cent, a gain of 8 per cent over the highest quality now exported from the Philippines. While sugar made from palm trees (of several species) is no novelty, the product has heretofore been unimportant in the world's markets.

Agricultural Education in Korea.—One example of the enlightened policy of the Japanese in dealing with their new possession, Korea (now officially called Chosen), is seen in the great progress of agricultural education in that country. Since 1906 the authorities have established thirteen agricultural schools and fifteen model experimental farms, the oldest and most important being the station at Suwon (Suigen), which is excellently equipped and managed, and compares favorably with some of the best institutions of this character in the United States. From this school there are 98 graduates who have taken the full three years' course, while 37 students have taken special shorter courses.

A Spanish Polar Expedition.—Several recent occurrences in Spain have betokened an awakening, in that country, of interest in scientific matters. Accordingly we are not surprised to hear that the Spaniards are planning an arctic expedition. The project was submitted to a recent meeting of the Royal Geographic Society of Madrid by F. J. Gisbert, who has had some experience in polar exploration, and a committee has been appointed to raise the necessary funds, which it is estimated will amount to $125,000. Senor Gisbert proposes to drift for three years in a trans-polar current—à la Nansen—starting from a point north of the Alaska coast, in 160 deg. west longitude, whence he expects to reach the Greenland Sea. Side trips are to made on sleds, in order that exploration may cover a zone of 100 miles on either side of the ship's position.

The City of Dairen, formerly called Dalny, is said to be the most up-to-date town in Manchuria. Here the Japanese are spending large sums annually on street, sewer and lighting improvements. Good hotels are maintained by the South Manchuria Railway (which is a semi-official organization). This line now runs express trains four times a week to connect with the trains of the Siberian Railway; they are unsurpassed in the Far East, being equipped with Pullman coaches, dining cars, and sleepers. The railway also operates a twice-a-week steamer service to Shanghai. The wharves of Dairen are said to be the finest in the Far East, vessels drawing up to 28 feet being moored alongside the quay. The port is open the year round, as the ice that forms in the bay is never thick enough to interfere with navigation. During the year 1910 1,389 steamers entered this port with cargo, and 457 in ballast, their tonnage aggregating 1,697,710.

Electricity

Wireless Telegraphy in the South Seas.—Wellington, New Zealand, will soon have one of the most powerful wireless telegraph stations in the world, with a radius of action of 1,000 miles. The government of New Zealand also intends to establish medium-power stations at the Chatham islands, a small group 600 miles southeast of Wellington, and at Raratonga, in the Cook group. As the latter will be able to communicate with Tonga, New Zealand will be within reach of Fiji.

Fender Chains for Panama Canal Locks.—In order to protect the gates of the Panama Canal locks, heavy chains are to be stretched across the lock chambers to receive the impact of vessels which get beyond control. These chains will be raised and lowered into grooves in the masonry by means of hydraulic mechanism. The hydraulic system will be controlled by solenoid valves, which will admit the water pressure to the cylinders. By using valves of this character, the chains may be controlled electrically from any desired central point.

Motor Trucks Need No Rest.—In a paper read before the Electric Vehicle Association of America, Mr. Hayden Eames called attention to the fact that horse-drawn vehicles must remain idle for a certain portion of the day in order to rest the horses. A recent investigation showed that the teams of the different express companies in New York city were idle forty per cent of the total working hours, much of this idleness being due to the fact that the horses needed rest, and that the periods of loading the wagons had to be suited to these rest hours. The motor vehicle on the other hand requires no rest, and hence requires no adjustment of the loading hours.

Electrically-cured Meat.—Some time ago we described in these columns an electrical method of curing hams, which was discovered by a Cincinnati packer. He found that by introducing an alternating current through the pickling brine the hams could be cured in from 30 to 35 days, as against 90 to 100 of the ordinary method. A large plant in Cleveland, Ohio, is now curing meat by this process. Ten 5,000-pound vats are in service. The current is furnished by a 100-kilowatt generating plant. The plant generates direct current for use in various capacities, and a portion of it is converted into alternating current by means of a rotary converter, to provide the energy used in the curing vats.

Resistance of Silicon at Various Temperatures.—Writing in the *Physical Review*, A. A. Somerville points to the fact that the resistance of the majority of metals increases steadily with the temperature up to their melting point, at which point there is a very sudden rise in resistance. Silicon, however, acts very differently. From zero to 350 deg. Cent. the resistance decreases gradually, and above this point, up to 500 degrees, it increases, reaching a value nearly equal to that of ordinary temperatures. Above 500 degrees the resistance rapidly decreases again. This curious phenomenon was observed in a large number of tests, showing that the result was not due to any peculiarity in a particular specimen, but was a property common to silicon.

Electrically-driven Road Roller.—A contractor in Independence, Kan., has had an electric road roller constructed for his use. The road roller is driven by a 10-horse-power motor, which obtains its energy through a flexible cable, 160 feet in length, connected to a transformer mounted on wheels. This in turn is connected with the supply system of the neighborhood, obtaining current at a voltage of 2,300 and slipping it down to 220 for use in the motor of the road roller. These flexible cables give the road roller sufficient radius of action for ordinary purposes, but when it is necessary to operate at a considerable distance from the only available transmission line, a temporary power transmission line is constructed very quickly. The cost of operating this roller in connection with the laying of brick pavements has been $6 per block. This amount covers the process of rolling the ground before and after the bed of crushed rock has been applied to it, and then rolling the brick after it has been laid upon the rock bed. The motor-driven roller weighs altogether 15,000 pounds.

Aeronautics

A Powerful Two-motor Monoplane.—Some months ago, in competition for the Gould-Scientific American prize, the Queen Aeroplane Co. produced a twin-motor monoplane fitted with two 50-horse-power Gnome motors. Piloted by Arthur Stone, this machine flew at Nassau Boulevard, but came to grief at the first turn. Short Bros., in England, recently built a two-motor biplane having the same equipment as the monoplane just mentioned, but it remained for a French engineer, M. Legrand, to bring out a biplane racer with two 100-horse-power Gnome motors. This machine was flown successfully by Camille Guillaume at Juvisy on October 20th last. The Coanda biplane which participated in the military contest recently also had two motors and a bevel gear drive to the propellers.

Rodgers Has a Bad Fall in California.—Transcontinental aviator C. P. Rodgers, after a week's rest at Pasadena, attempted to fly the remaining 25 miles of his journey on the 12th inst., and to land at Long Beach. He had gone but a few miles when he was forced to alight at Cobina Junction because of engine trouble. After making temporary repairs he flew on again as far as Compton, where, in making a forced descent, he fell 100 feet sustaining concussion of the brain, severely sprained ankles and internal injuries. Rodgers' mind was a blank for thirty hours. He has since explained his fall as a result of sheer nausea which overcame him when flying at a height of 1,000 feet. He attempted to descend, but when 100 feet from the ground became unconscious and lost control of the machine.

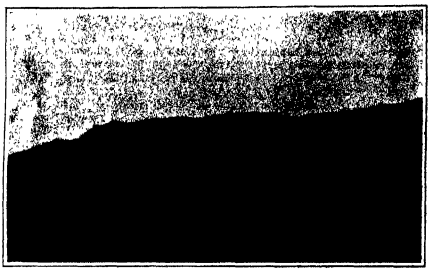
Test of Vaniman's Airship "Akron."—After a considerable delay, the first test flight of the "Akron" took place at Atlantic City on November 4th. Manned by her full crew of five, the airship maneuvered for more than an hour above the inlet at Atlantic City. A strong breeze arose, and the airship was progressing against it splendidly when Vaniman fell across the rubber hose connecting the motor with the radiator and broke it. Knowing that the motor was about to stop, Vaniman steered his vessel down head on into the shallow water covering a mud flat. Not until the tide rose were the motor boats able to rescue the disabled airship. A 70-mile gale on the 12th inst. damaged the "Akron's" shed but the craft itself was not injured. Vaniman has given up the idea of making the trip this year.

Recent Aeronautic Fatalities.—By a strange coincidence of fate a parachute-jumper a celebrated balloonist, and a well-known aviator met their deaths within a few days in widely diversified ways. When he cut loose from his balloon 2,000 feet in the air at Guthrie, Okla., on November 10th Samuel Heller's trapeze bar broke. He managed to hang on until within 200 feet of the earth, when he fell and was killed. Edgar W. Mix, the American electrical engineer and balloonist, who won the Bennett Cup race in 1909, committed suicide by jumping overboard from a channel steamer on the 12th inst. Herr Pietschker, a well-known German pilot of the "Albatross" biplane, fell to his death at Johannisthal, near Berlin, on November 15th. His neck was broken.

Robinson's Flight Down the Mississippi.—After a week's delay owing to stormy weather, Hugh Robinson, with his Curtiss hydro-aeroplane, ascended from the surface of Lake Calhoun at Minneapolis on the 17th ult., and started on his proposed flight to New Orleans. With the wind behind him, he flew 110 miles to Winona, Minn. in 1 28, or at the rate of 88 miles an hour, where he landed in the Mississippi river. In landing he struck a snag and damaged his hydroplane float. On October 19th he covered 91 miles in 83 minutes—an average speed of 65¾ miles an hour. His flight down the river was terminated at Rock Island, Ill., the next day, as the different cities which had given him guarantees withdrew them when they found he would probably make the flight without. He set a new record in that he carried mail for over 300 miles and collected and dropped off letters at the various towns at which he stopped. His flight is the longest ever accomplished with a hydro-aeroplane.

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them

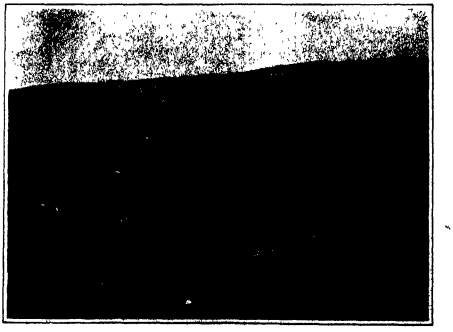


Floods Caused by Over-grazing

AMONG the recent publications issued by the Forest Service is Bulletin 91 entitled "Grazing and Floods, A Study of Conditions in the Manti National Forest, Utah," by Robert V R Reynolds, Forest Examiner This bulletin consists of a recital of the triumphs of strict protection of the cattle and sheep range on a typical region subject to floods and erosion The facts brought out in this publication plainly show that the absence of floods in the Manti National Forest can be attributed only to the protection afforded by the excellent crop of forage on the area closed to grazing

"The Manti National Forest in central Utah has for a number of years been subject to severe floods after all storms of more than usual violence, with corresponding scarcity of water during periods of drought A careful study made during the spring and summer of 1910 showed clearly that this condition of erratic run off had followed heavy overgrazing in the mountains, and that where grazing had been restricted the conditions were rapidly improving The problem of securing an equable streamflow is a vital one to the towns located along the base of the Wasatch Range These are not only dependent upon the streams for their water supply, but they have also suffered heavily from floods in the past and are still constantly in danger" Again "In 1910 a committee composed of two sheepmen, two cattlemen, and a merchant, representing the towns of Orangeville and Castledale and surrounding agricultural settlements in Emery County expressed the belief that floods are due mainly to the denuded condition of the range which has resulted from over-grazing, and requested the protection of these watersheds In support of their request they stated that for many years after the settlement of Castle Valley in 1878, floods were unknown Soon after the ranges on the heads of the streams were heavily stocked with sheep and cattle, however, freshets began to occur with each heavy rain during the summer months, and these have steadily increased in volume and destructiveness"

Mr Reynolds contrasts the former conditions of grazing distinctive in most of its aspects, with the well regulated methods now generally in vogue on all the principal water sheds where the government still holds title to the land The period of strict grazing supervision is one of the most remarkable epochs in the history of forestry and conservation



Until one examines the entire ground carefully it is impossible to see why the Forest Service annually comes to Congress as a solicitant of favors It has the right to demand support This support it does not always have because its work in some parts of the West often runs counter to organized sheep and cattle men Formerly it was the fashion in the West to ridicule the work of the Forest Service as being largely theoretical, and perhaps a part of the earlier work was that came for the humorist in that day but that day is past and great results are being accomplished One is obliged to admit that the triumphs of the Forest Service have been many and that a large part of its success is due to the original work of the ambitious young men who have entered the service during the last ten years and whose painstaking endeavors are beginning to bear fruit

The Earning Power of Chemistry

IN a public lecture to business men delivered recently under the auspices of the Indiana Section of the American Chemical Society Mr Arthur D Little claims for chemistry that it is the most fundamental and likewise the most comprehensive of all the sciences

Among the practical applications of chemical research, Mr Little mentions the work done by Brown and Mrs. Richard in the laboratory of the Massachusetts Institute of Technology, "work which has been the means of saving countless lives throughout the world and has led to such understanding and made possible such control of sources of pollution as to almost justify the statement that for every case of typhoid fever some one should be hanged"

Mr Little assures us that chemistry can now determine in advance the suitability of a given water supply for use in boilers or for the requirements of any special line of industry, as paper-making, dyeing, cloth finishing, brewing and so on.

"Chemistry pervades the packing industry, reducing the cost of food by utilization of by-products of the most varied character, from oleomargarine to glycerine and soap and from soap to pepsin and adrenalin

"Carbon disulphide made in the Taylor electric furnace has preserved the wine industry of France by destroying the phylloxera, as it is ridding our own fields of prairie dogs and our elevators of rats and mice. Bread-making and brewing are coming each year more and more within the recognized domain of chemistry, which is at the same time greatly enhancing the value of our staple crop by the increasing production of glucose, corn oil and gluten. Exactly one hundred years ago Kirchhoff discovered the inversion of starch to glucose by dilute acids. To-day the United States alone is richer by $20,000,000 a year by reason of that discovery."

Among other instances of the commercial utilization of chemistry Mr. Little mentions increased crop yields by proper fertilization, increased profits by utilization of the cotton seed for oil, cattle feed, adaptation of the short fiber adhering to the ginned cotton seed hull to the making of smokeless powder and the stalks of the cotton plant to paper-making.

There are also to be considered wool degreasing processes which convert wool grease into oleic acid, soap, lubricating oils and potash and ammonia salts; the carbonization of cotton fabrics; the wonderful processes whereby coal tar is made to yield perfumes, dyes, aseptics, explosives, photographic developers and a host of other substances; the modern development of artificial silk from cellulose, the manufacture of artificial horsehair and of artificial bristles composed of cellulose acetate; the production of illuminating gas; the introduction of the modern gas mantle of the Welsbach type; the chemical research which has resulted in improving the incandescent lamp, so that in the last ten years there has resulted a saving of twenty-four million dollars a year in the cost of lighting, as compared with the cost of equal illumination by the older types of lamp; the analysis of flue gases, so as to save fuel

Mr Little concludes with a quotation from Prof Robert Kennedy Duncan

"During the next five years the small manufacturer who is swept out of existence will often wonder why He will ascribe it to the economy of large scale operations, or business intrigues or what not, never knowing that his disaster was due to the application of pure science that the trust organizations and large manufacturers are already beginning to appreciate"

Eye Color and Mental Traits

IN reviewing in *Science* the third edition of Punnet's little classic "Mendelism," W. E Castle cites the following interesting passage:

"A discussion of eye color suggests reflections of another kind. It is difficult to believe that the markedly different states of pigmentation which occur in the same species are not associated with deep-seated chemical differences influencing the character and bent of the individual. May not these differences in pigmentation be coupled with and so become in some measure a guide to mental and temperamental characteristics? In the National Portrait Gallery in London the pictures of celebrated men and women are largely grouped according to the vocations in which they have succeeded. The observant will probably have noticed that there is a tendency for a given type of eye color to predominate in some of the larger groups. It is rare to find anything but a blue among the soldiers and sailors, while among the actors, preachers and orators the dark eye is predominant, although for the population as a whole it is far scarcer than the light. The facts are suggestive, and it is not impossible that research may reveal an intimate connection between peculiarities of pigmentation and of mind.

Weather "Kiosks" at Home and Abroad

Meteorology for the "Man in the Street"

By C. Fitzhugh Talman

THE conservative behavior of Weather Bureau thermometers during the heated term has always been viewed with a certain degree of dissatisfaction by the non-scientific portion of the American public. After a particularly torrid day in an environment of brick and mortar, asphalt and steaming humanity, the wilted citizen, whose sensations have registered a temperature of 100 or more, feels aggrieved at a newspaper weather report recording an official maximum of 85. His only consolation was, until recently, the thermometer at the corner drug-store. This imposing-looking instrument usually soared nearly or quite high enough to confirm his personal estimate of the day's weather; especially if it happened to be hung in such a position as to bask in unobstructed sunshine during a part of the day. Some of these drug-store thermometers are fearfully and wonderfully made. As adjuncts of a quasi-scientific branch of trade they enjoy a certain prestige—along with the charts, also affected by drug-stores, in which the professional long-range weather prophet outlines the meteorological conditions for a month in advance on the basis of the moon's phases, the configuration of the planets, or the maxima and minima of sun-spots.

Fig. 1.—German weather kiosks in the making.

At meteorological observatories the instruments are exposed in such a manner as to register, as nearly as the general surroundings will admit, the natural rather than the artificial weather. If, as in the case of most stations of the national Weather Bureau, the location happens to be the heart of a city or town, the ideal, not wholly attainable, is to record the conditions that would prevail if the buildings and pavements were not there. The abnormal weather of a city street is of no importance in gaging the weather of the country at large, either with a view to compiling climatic statistics or to providing information of current conditions for the use of the scientific forecaster. On the other hand, the demand of the "man in the street" for an accurate record of the conditions prevailing in his own little sphere is natural and legitimate; and the official weather service has recently responded thereto by establishing "kiosks."

The first Weather Bureau kiosks were erected in the year 1908, and they have now become familiar landmarks in most of our largest towns. The name "kiosk" officially applied to them is convenient, rather than appropriate. Their architecture is severely classical, and therefore as remote as possible from that of the oriental structures to which this name properly belongs.

Meteorological instruments installed in little pavilions on the public streets are familiar to every one who has traveled in continental Europe. In German speaking countries these structures are called *Wetter-säulen* ("weather-columns"), as they have a somewhat columnar form. In French they appear to have no generic name, but the writer is aware of one case in France—viz., at Le Mans—in which an installation of this general character has been called a "kiosque météorologique" for the past twenty five years, although its appearance is not in the least oriental. No English name for these structures existed—probably because the thing itself was unknown in English speaking countries—until the Weather Bureau decided to install such arrangements in this country. The catalogues of several foreign instrument makers were examined with a view to finding the most suitable form of construction. Here the name "kiosk" was encountered as applied to one of these edifices that happened to have some semblance of oriental architecture. *Faute de mieux* this name was adopted by the bureau, although an entirely different style of construction was decided upon.

The external appearance of the Weather Bureau kiosk, which was designed in America, is shown in Fig. 2. The structure, which is of cast iron, painted a light color, is square, and the instruments are installed on the north side so as to be sheltered as much as possible from the direct sunshine. The other three sides are used for posting weather maps and bulletins and other literature of general interest pertaining to the weather and climate of the locality. The location chosen is the busy center of a town, either a public park or the pavement of a principal street.

Air is freely admitted through gratings at the top and base to the roomy interior, and into this central space project the bulbs of the thermometers and the other actuating parts of the instruments, which are thus screened from the radiation of surrounding objects. The set includes a hair hygrometer, with a scale of percentages of relative humidity, a plain mercurial thermometer of large size, graduated on the stem in conspicuous figures, self-registering maximum and minimum thermometers, the indexes of which are set by a magnet, a tipping-bucket rain-gage, the receiver of which is placed on the roof of the kiosk, while the dial, recording hundredths of an inch of rainfall, is exposed to view in the north panel, and a thermograph, making a continuous record of the temperature on a band of paper providing for a two weeks' registration. Printed labels briefly describing the several instruments render their use clear to the non-scientific public. The instruments are kept in order, the record-sheets changed when necessary, the

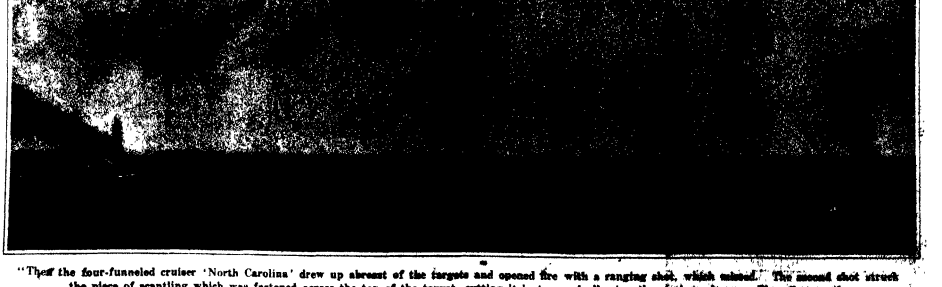
A Landsman's Log Aboard the Battleship "North Dakota"—IV

By J. Bernard Walker.

This landsman's Log is written by the Editor of the SCIENTIFIC AMERICAN *as a preliminary to a magazine Naval Number to appear December 9th, which will be comparable in its size and completeness with the Naval Number issued during the Spanish War. In one respect it will be unique, for it will contain a signed message from President Taft, and will be written entirely by prominent officers of the Navy, each a specialist in the particular field that he covers. The leading article, moreover, will be from the pen of the Hon. George von L. Meyer, the Secretary of the Navy. The illustrations will consist of special photographs taken during the recent maneuvers and target practice of the Atlantic Fleet on the Southern Drill Grounds.*

THE landsman's log will fail of its purpose if it leaves an impression that target and battle practice with guns big and small constituted the whole of the activities of the Atlantic fleet on the Southern Drill Grounds. Nor must it be supposed that the gunnery consisted exclusively of firing by individual ships against individual targets. Every probable variation of war conditions was reproduced. I have a vivid recollection of the particular day when a division of four ships left the fleet steamed in column until they were hull down, then turned, simultaneously, four points to starboard, and, moving at high speed in *echelon*, or diagonal, formation, delivered their broadsides upon a single target 9,000 to 12,000 yards distant. This maneuver, seen, as I saw it, on a glorious September afternoon, was a most stirring and picturesque naval spectacle—with fifty square miles of the sapphire blue ocean for a stage and ten thousand men on a three-mile line of battleships for audience. Two or three points off the starboard bow of the 'North Dakota,' and some four miles distant, was the target, which was being towed at ten knots on the same course that we were following. Abreast of us and five hundred yards to port was the 'New Hampshire," flagship of the Second Division; and, ship beyond ship, I could see the other eleven battleships steaming abreast, each like the 'North Dakota," crowded on its bridges and forecastle deck with eager spectators of the attack. The firing division, six miles distant from the target, was some seven miles off the port bow; the farther end of our line. And so, from the observing fleet we watched the four ships manœuver now firing at the extreme bearing, for the whole broadside, forward, then turning to bring the batteries to the extreme bearing aft—and throughout it all at the target, there soared majestically skyward those snow-white columns of water that told of the accuracy or otherwise of the shooting.

On other days individual ships would attack two widely separated targets at once—and again, ships would be sent out at night to try their 12-inch batteries upon targets that were 9,000 yards distant; while throughout all these operations the corps of wireless operators were working out special problems relating to their own special work, and particularly with respect to "interference."



"Aerial gun practice, however, is not confined to one-pounders and three-pounders. The Springfield rifle, whose bullet, at 45 degrees elevation of the gun, reaches a height of 6,800 feet, is such an effective piece that it will afford no inconsiderable defense against any aeroplane that might attempt to execute feats of bomb-dropping."

Every era of naval history has been fruitful, in varying degrees, in novel inventions and improvements and the many new problems which they have inevitably introduced. High explosives, electrically-operated mines, smokeless powder, the rapid-fire, high-velocity gun, the automobile torpedo, the torpedo boat, the destroyer, and the submarine have each in turn exercised their powerful influence upon the design and maneuvering of ships. To-day there has appeared a new engine of warfare, more puzzling than any of its predecessors, because, unlike them, its operations are not confined to the sea, but have invaded an entirely new element—the air.

Although the attitude of the Navy Department toward the so-called "aeroplane warfare" is conservative, it is by no means reactionary. While it is realised that much of the speculation as to the offensive capabilities of the aeroplane is premature and not justified by the present state of its development, naval men concur in the belief that, when a suitable type of machine has been evolved, the aeroplane will play an important part in the strategy of the future. This conviction has been deepened as the result of the experiments carried out by Ely and Curtiss in the effort to produce a machine suitable for naval scouting. The Curtiss "Triad," as it has been called, has shown that it can start and alight from a calm sea, and the work of this remarkable machine, following the feat of the late lamented Ely in alighting on the deck of a warship and starting therefrom, which has been repeated on other occasions, has carried the aeroplane scout a long step forward toward the stage—still a long way distant—when it can be regarded as a "perfectly" reliable medium for naval scouting. The exigencies of naval warfare demand that the aerial scout shall be capable of starting on its mission and gathering and transmitting its observations *in any weather*. With the present form of pontoons this is impossible, and it is difficult to imagine any form of sustaining device that would carry an aeroplane over the waves of a rough sea at the speed which is necessary for flight. It is possible that the solution of the difficulty will be found in the construction of special aeroplane tenders—high-speed vessels, with long, unobstructed reaches of deck, suitable as starting and landing places for the machines. Such vessels, if they were provided with large rudder area and designed for unusually quick maneuvering and rapid changes of speed, should be accessible for the safe return and landing of aeroplanes, even in considerable stress of weather.

But to return to our log, which, if it is to be true to its name, must contain a record, not of theories and

"Then the four-funneled cruiser 'North Carolina' drew up abreast of the targets and opened fire with a ranging shot, which missed. The second shot struck the piece of scantling which was fastened across the top of the target, cutting it in two and allowing the cloth to droop. The effect on the firing was instantaneous; for the range being now known, the gunners put shot after shot through the targets."

opinions, but of the actual work of the Atlantic fleet on the Southern Drill Grounds, as seen by civilian guests, and of the impressions which it has left upon the civilian mind.

One of the most instructive and novel of the many visits paid to other ships of the fleet was an early morning trip to the "Michigan" for the purpose of witnessing aerial target practice. On mounting the gangway we found that the quarter deck had been turned into a veritable kite factory. Yards of red bunting, reels of wire, and a plentiful supply of light pine scantling was in the process of being built up into a number of box kites and several square targets measuring each about twelve by fifteen feet.

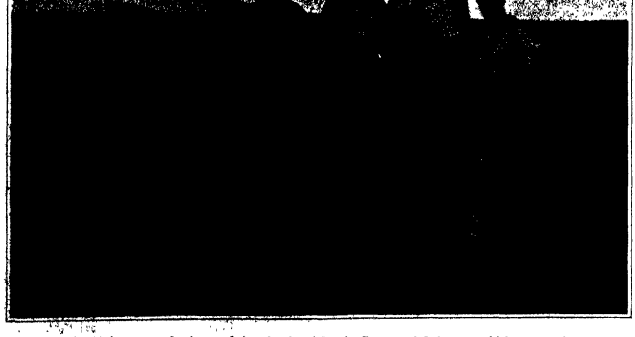
Now the handiness of the sailorman is proverbial; but I never knew till I got aboard the "Michigan" that he was an expert kite builder, and since I am perfectly certain that the building of box kites is not to be found in the curriculum at Annapolis, I may be pardoned my surprise and appreciation at seeing a stalwart lieutenant, armed with hammer, pliers, and a bag of wire nails, knocking a box kite together with as much facility as he would handle a sextant or a range finder, plot his ship's course, or bring a 20,000-ton battleship to her moorings.

The box kites completed, they were flown in a group of three from the stern of the "Michigan;" and after much hauling and slacking, and, or shall we say "backing and filling," were coaxed out of the bewildering cross currents of air, which formed the aerial wake of the ship, into the light and steady breeze which was blowing. The end of the cotton rope to which the kites were attached was made fast to a steel wire, which led through a haul down block up to an extemporized winding drum, at the head of the port gangway to the boat deck. As the wire was paid out, the targets were attached to it in the position shown in our engraving, and when they had been lifted to a height of some 300 feet above the water (the limit of the lifting power of the kites in the light air which was blowing) they were ready for the firing.

Two ships had been delegated to the work of destroying the enemy; and as soon as the targets were ready one of the "Connecticut" class of battleships steamed rapidly out from the fleet until she was abreast of the targets and about 2,000 yards distant therefrom. She opened fire with her starboard battery of 8-inch, 14-pounders, fired some two or three dozen rounds, and then steamed in at full speed to take a closer look at the targets and see how often she had winged the enemy. Not a single shot had found the mark! Then the four funneled cruiser "North Carolina" drew up abreast of the target and opened fire with a ranging shot which missed. The second shot struck the piece of scantling which was fastened across the top of the target, cutting it in two and allowing the cloth to droop in the center. The effect on the firing was instantaneous, for, the range being now known, the gunners put shot after shot through the squares, making a total of about a dozen hits. The different results accomplished by the two ships showed clearly the need for some form of tracer, such as I described in the last section of the log, dealing with night firing, to show the the course of the shells through the air and enable the sight-setter to make the proper corrections on the sight bars.

During the progress of the firing, the ordnance engineer of the "Michigan," who had charge of the kite flying, drew my attention to a phenomenon, which he suggested would form an interesting subject of speculation for the readers of the SCIENTIFIC AMERICAN. He asked me to note that after a 12-inch gun was fired, two distinct reports of the discharge were noticeable—one a sharp characteristic snap, which seemed to come from the locality of the target, and the other a more muffled report which reached the ship a few seconds later. The sharper report, by my timing, reached the "Michigan" in about 2½ seconds' time, the second report in about 5½ seconds' time. Now the velocity of the shell when it leaves the muzzle is about 2,800 feet per second; the velocity of sound is about 1,140 feet per second. The distance from the gun to the "Michigan" and the target (which was about 300 yards astern of the "Michigan") was about 6,000 feet, so that the sharp report traveled to the ship at the velocity of the shell and the duller, muffled report at the velocity of sound.

Now here is a pretty little problem in acoustics which we present for consideration. How came it that the first report of the gun reached the ear in about half the time that it should have taken, by all the laws of acoustics, in making the journey? Some one on the ship suggested that the first report was due to the noise of the shell as it passed the ship. But the "scream" of a shell is continuous, rising to its maximum intensity as it passes the listener, and dying away as the distance increases. Another suggestion was that a part of the sharp sound wave of explosion traveled in the attenuated air immediately behind the shell, being, in fact, "paced" by the shell, and that this portion of the air wave was sufficient to produce the loud, snappy effect above referred to.



The ordinary gun mount on board ship allows of an elevation not much above 15 degrees. For successful defense against aeroplanes, a higher elevation is necessary, and an experimental one-pounder is now being developed by the Bureau of Ordnance which, at an elevation of 45 degrees, will throw its shell to a height of 9,000 feet and a maximum range of 6,100 yards. With 85 degrees of elevation the shell will reach a maximum height of 18,000 feet.

Aerial gun practice, however is not confined to one-pounders and three pounders. The Springfield rifle, whose bullet reaches a maximum height of 6,800 feet, is such an effective piece that it will afford no inconsiderable defence against any aeroplane that might attempt to execute those feats of "bomb dropping" which are so popular a subject in the pages of the magazines and the Sunday papers. This rifle fires a 0.30 bullet with a muzzle velocity of 2,700 feet per second. Held at an angle of elevation of 45 degrees, the bullet will reach a maximum height of 6,800 feet and travel to a maximum range of 5,500 yards.

(To be continued.)

"The ordinary gun mount on board ship allows an elevation not much above 15 degrees. For successful defense against aeroplanes, a higher elevation is necessary."

"An experimental one-pounder is now being developed by the Bureau of Ordnance, which at an elevation of 45 degrees will throw its shell to a height of 9,000 feet; and with 85 degrees of elevation will reach a maximum height of 18,000 feet."

The Demand for Young Men in Electrical Engineering

By Dugald C. Jackson, of the Massachusetts Institute of Technology

ANY branch of engineering is an exacting mistress for the man who makes it his profession, and this is particularly true of electrical engineering, which demands from its followers an unusual breadth and variety of industrial knowledge because it enters into the processes of almost all of the great industries found in the nation. The scope of an electrical engineer's work may be indicated by many striking examples. Both of the world's means of quick intercommunication, the telegraph and telephone, use electrical processes and those of the telephone are so complex that they demand in their management a high class of engineering skill. City, suburban and interurban traction systems have fallen almost entirely under the monopoly of the electric motor, and railway freight traction over mountain divisions of steam railroads seems likely to soon come under the same influence. The electrical transmission and distribution of power have put artificial illumination of streets and houses on a plane never previously reached or imagined, and their processes are being constantly improved and extended. Even in the manufacturing industries, the use of electrical power has served to increase the output and decrease the cost of product in many different kinds of works, and the utilization of electric power is therefore greatly enlarging.

It is obvious that adequate training for a profession that brings its followers into contact with so many of the activities and nearly all of the industries of the nation must consist essentially of those principles of science and humanity which are fundamental to all, and an electrical engineering course must therefore be made strong in chemistry, physics, mathematics and applied mechanics, and those subjects must be associated with the study of machinery, stationary structures, hydraulics and steam engineering. Also along with these, extended study is required of the fundamental nature of the flow of electric current, the phenomena of electromagnetism, and the ways in which these may be usefully applied in the world's activities and particularly in industrial affairs. Very little time can be given to those features of engineering practice which are of a nature which can be mastered with comparative readiness by observation after graduation. An appropriate electrical engineering course sufficiently occupies the time available for undergraduate study if it is confined to cultivating a knowledge of scientific and eco-

A New Process for the Felling of Trees

By Dr. Alfred Gradenwitz

THE attempts from time to time to cut trees with a wire heated by electricity so far have not given satisfactory results

Now a Berlin inventor, Mr Hugo Gantke has recently succeeded in designing an extremely simple device for the mechanical felling of trees The trunks are cut by the fraction of an ordinary steel wire about one millimeter in diameter (No 18 B & S gage) which, as shown by practical tests, is able to saw through a tree about 20 inches in diameter, in six minutes

The steel-wire, driven by an electric motor, is heated so intensely by friction on the wood as to burn a thin carbonized kerf, which is both smoother and cleaner than the cut of a saw The charcoal layer adhering to the trunk is extremely thin and allows the structure and any disease of the wood to be distinctly recognized It enables the tree to be marked with chalk, and at the same time serves to preserve any trunks that may be left temporarily in the woods

Unlike other saws, this felling machine will work freely even on the thickest trees, without requiring any wedges to be inserted into the cut, for instead of any shavings we have only smoke and steam and hence there is no danger of the cut's becoming obstructed The trees may be cut close to the ground, or even below the ground as far down as the beginning of the roots will permit In the latter case the stump may be safely left in the soil The electric motor that drives the steel wire is placed where it is not in danger of being struck when the tree falls

While mechanical operation is in itself much more rapid than hand-labor, a further acceleration is derived from the absence of any intervals of rest between two cuts As a new piece of steel wire costing but a few cents is taken for each cut, there is no loss of time due to the sharpening of saws, etc Only one man is required to operate the machine as against two men working with hand saws, and the larger the tree the higher is the relative cutting speed

When electricity is not immediately available, it can be generated by any existing steam or water plant It may frequently be found advantageous to use a portable power-plant consisting of a 10 horse-power gasoline motor and dynamo which may be installed temporarily in a central location A flexible cable may connect the dynamo with the felling machine which can be readily transported and operated by one man

An important advantage of the new method arises from the absence of any waste, the cut only two millimeters (0.079 inch) in thickness being perfectly smooth and level, while rear axes and saws are bound to injure the trees to a considerable extent

Review of the Report of the Commissioner of Patents

THE Commissioner of Patents, Hon Edward B Moore, in his report to the Secretary of the Interior, for the fiscal year ending June 30th 1911 makes some very vigorous recommendations regarding needed legislation for the United States Patent Office, besides touching upon the work already accomplished along the line of improvement in that branch of the service

The Commissioner reports the work of the Office to be in a very satisfactory condition and practically up-to-date in all its branches. He states that while Congress has been fairly liberal in its appropriations for the increase of salaries and providing new positions, thereby enabling the institution of many needed reforms, there is still a certain percentage of separations from the Office of trained examiners who accept offers of larger salaries from outside firms and corporations. The Commissioner, however, does not ask for an increase in the salaries of the examining corps at this time.

Gains in Efficiency and Economy.

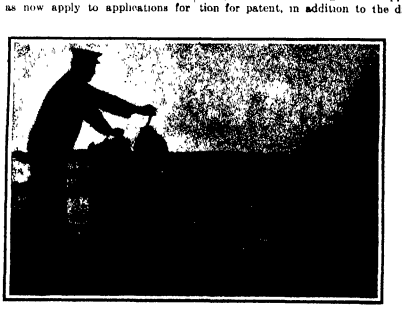
The Commissioner reports that a saving of from five to six thousand dollars annually has been the result of the change in the manner of printing certificates of trade-mark registration, and that this saving will be continuous annually The changes in the rules of practice relating to trade-marks, which were effective November 1st, 1911 are expected to accomplish a considerable saving of time to examiners in searching this enormous class of applications At the present time it is required that the examiners search through some 20,000 pending applications, which are in the various stages of prosecution It is proposed to have the same rules apply to applications for the registration of trade-marks as now apply to applications for patents, that is, they must be amended within one year or the application becomes abandoned, the applicants still having the right to file new applications if desired

Plans are under way to accomplish an economy in the method of publishing and issuing the *Official Gazette*, to the extent of saving between eighty and ninety thousand dollars a year This will, it is believed, increase the efficiency of the *Gazette* as a work of reference, reducing its bulkiness and making it more compact and easily handled

Legislation.

The Commissioner renews his recommendations with regard to the urgent legislative needs of his Office Paramount is the bill recently reintroduced by Mr. Oldfield, the Chairman of the House Committee on Patents, which provides for the elimination of one of the appeals within the Patent Office This measure contemplates the consolidation of the board of examiners-in-chief with the Commissioner and the two assistant commissioners, forming one judicial tribunal to hear appeals taken from the primary examiner. It is argued by the Commissioner that this will accomplish an immense saving in time for the passage of appeals through the Patent Office and will also be a saving in money to the inventor, who will thus be relieved of the necessity for paying for a double appeal in the Patent Office in carrying his cases through to the Court of Appeals of the District of Columbia, the court of last resort in such cases.

The policy of the Government at the present time is to avoid all unnecessary duplication of work and relieve the officers of the various branches of much work that has become burdensome to all concerned, as well as wholly unnecessary. Mr. Moore states that it is practically the unanimous opinion of inventors and manufacturers throughout the country that one appeal should be eliminated in the Patent Office in order to save the great cost and loss of time now involved in obtaining a final adjudication and consequent grant of patent



He further states that he has been supported widely in this effort to facilitate business, and states that this is an important part of the plan to expedite business and to grant patents to inventors within a reasonable time, which they have demanded, and to which they are entitled. Bills embracing the substance of this recommendation were introduced by Senator Smoot and were passed by the Senate. No action, however, was taken upon these bills in the House.

Other measures of importance are strongly advocated by the Commissioner One provides for the filing with an application for patent, in addition to the drawing, two photographic copies of such drawing This imposes upon every applicant for patent an additional statutory requirement, to wit, to file with each application of which a signed and attested drawing forms part, two photographic copies of such signed and attested drawing. The purposes of this requirement are to guard against and enable the detection of unauthorized changes in the original drawing or abstraction of such drawing and substitution of another; and to lessen the danger of serious mistakes on the part of the Office in failing to detect interferences between co-pending applications for the same invention.

An important measure is that which requires that an application for patent shall be prosecuted within six months after any action by the Patent Office. The bill is aimed to cause the more speedy prosecution of applications and should have the effect of preventing the holding of applications within the Office for a great length of time for the purpose of extending the patent period.

The Commissioner also urges the passage of the bill which authorizes the issuance of certificates of correction in cases where the patent as printed does not conform to the record.

In connection with the recommendation for elimination of one of the appeals in the Patent Office, the Commissioner furnishes a table showing the extent of the heavy appeal docket for the fiscal year, which epitomized, shows the number of interferences declared to be 1,537; appeals to the examiners-in-chief, 1,102; appeals and petitions to the Commissioner, 2,912.

Portable device for mechanical felling of trees.

The Heany Cases.

The Commissioner reports the termination within the Office of the investigation arising out of the original criminal trial of Heany, Barton and Everding, for forgery and violations of Sections 5408 and 5440 of the Revised Statutes. The criminal trial, which resulted in the conviction of Barton and Everding and the acquittal of Heany, was followed by the Commissioner's order against Heany to show cause why certain interferences in which his applications were involved, should not be dissolved and his applications included therein and other applications also tainted with fraud should not be stricken from the files and treated as a nullity. The hearings resulting from this order were before the First Assistant Commissioner, owing to Mr. Moore's being occupied with other important duties connected with the conference at Buenos Aires and the conference at Washington. The hearings began in the summer of 1910 and lasted for several months.

The conclusions reached, ordering that the Heany applications be stricken from the files, as set forth in the First Assistant Commissioner's decision printed in the *Official Gazette* of October 21th, 1911, meet with the Commissioner's unqualified approval, and Mr. Moore also takes occasion to express his appreciation of the valuable assistance rendered by former Examiner-in-Chief L. H. Campbell, Mr. F. C. Skinner, at present Examiner-in-Chief, and by Mr. Eugene D. Sewall, Examiner of Classification, who acted as a Board in the original investigations preceding the criminal trial; and of the services rendered by Mr. Skinner and Jesse C Adkins, Esq., at the trial, and by Mr Adkins and Chief Law Examiner Webster S. Ruckman, during the investigations arising out of the order to show cause.

Mr. Moore states that the Department of the Interior and the Patent Office are to be congratulated at the very satisfactory termination of the criminal case and the Office investigations as well. He reiterates his statement made in a previous report and to the press that the Heany case is the only one of its kind that has ever occured in the Patent Office during the 117 years of its history.

The Patent Bar.

The Commissioner invites attention to the necessity for legislation which would result in the establishment of a patent bar. It is strongly urged that a law be enacted which will provide that before an individual shall be permitted to practice before the Patent Office, he be required to pass an examination as to his moral, legal and technical qualifications, and that a committee be appointed by the Commissioner of Patents composed of officials in the Patent Office and patent attorneys of well-known standing in the profession, who shall conduct the examination under the Commissioner's supervision, the report of such committee to be subject to his approval.

The Commissioner states that a redraft of a measure looking to this reform will with the Secretary's approval, be prepared and presented to Congress in a short time.

Scientific Library and Other Matters.

A complete reorganization of the Scientific Library is contemplated by the Commissioner, who states that a classification of the enormous amount of foreign publications, including patents and works of reference, and books of great value to attorneys and examiners in their search for anticipations in the arts, is an immediate necessity. The Commissioner is desirous of having the whole subject

thoroughly digested, so that it will be readily accessible and thereby do away with much expense and loss of time.

The Commissioner asks for an additional force to aid in this work, and also requests an increase in the force of translators.

International Conferences and Treaties.

The Fourth International Conference of American States held in Buenos Aires in 1910, and the Conference of Washington of the International Union for the Protection of Industrial Property, 1911, are both referred to by Mr. Moore as being productive of much good in the harmonizing of international relations with regard to patents, trade-marks and copyrights. The three conventions adopted at Buenos Aires were prepared by Mr. Moore and are strictly in the interest of the manufacturers, inventors and authors of the United States. These three conventions have all been approved by the United States Senate and are awaiting ratification by the twenty Latin American nations represented, several of whom, it is understood, have ratified them, and others still have them under consideration.

The conference at Washington to amend and consider the Paris Convention of 1883, was attended by delegates from forty nations, including nations adherent to the Paris Treaty and those specially invited to participate, but who had no voting powers. Important conventions affecting changes in both the patent and trade-mark laws were discussed at the conference, and the final convention was adopted and signed by the delegates subject to the ratification of their various governments. The language of the conference was French as provided by the Treaty of Paris.

Mr. Moore, who was chairman of the American delegation, states that it was the announced opinion of all the delegates present that it was the most successful conference of the Union ever held. He states that aside from the very desirable changes of the laws of nations relating to patents and trade-marks, there is another important underlying reason why these conferences are desirable. They bring together men familiar with the subjects to be discussed, who become well acquainted and talk over their differences not only in formal session, but in private conversation, while mingling socially.

During the conference the Commissioner received a cablegram announcing the passage by the German Reichstag of a law upholding the treaty between Germany and the United States, providing that patents of American inventors should not be revoked by the German government for failure to work or manufacture the same in Germany within four years, provided, however, the same is manufactured in the United States in the same period of time. Mr. Moore personally negotiated this treaty with Germany and in addition succeeded in accomplishing the revision of the laws of Norway, Sweden, and Switzerland, so that the manufacture of patented inventions in those countries by United States citizens is not longer required in order to sustain their patents. It is thought that several other countries will speedily follow this example.

Urgent Need for New Quarters for the Patent Office.

As a climax to his other very strong and well-considered recommendations, the Commissioner reiterates with renewed emphasis the very imminent need of new quarters for the United States Patent Office. He offers in his report two remedies for the over-crowded and wholly inadequate conditions that now exists. The first is a complete remodeling of the present building in accordance with plans which he has drawn up and which have been approved by the Supervising Architect of the Treasury and the Architect of the Capitol. The second is the construction of a new building on the site immediately north of the library of Congress, and which was contemplated by the Daniels bill, introduced in the 61st Congress.

The Commissioner urges many excellent reasons in support of his contention, not the least of which is the constant danger from destruction by fire which threatens the valuable archives of the Patent Office, and the loss of which would work irreparable damage to the commercial interests of this country. Considering the fact that there is a net surplus in the United States Treasury earned by the Patent Office and paid in by the inventors amounting to more than seven millions of dollars, the Commissioner believes it only fair that part, if not all, of this sum should be expended in the furnishing of larger and better quarters, with modern facilities for the force, which would then be in a position to accomplish the best possible results in the work for which the outside inventive public pays the total cost.

This is a matter in which the whole country is interested and it should be the avowed determination of every manufacturer, merchant and inventor in the United States to aid in every way possible, within his power, the building of a newer, greater and safer Patent Office.

Death of Examiner McKee

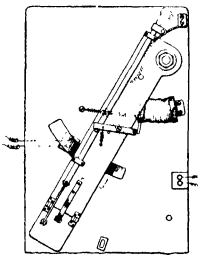
ROBERT M. McKEE, an assistant examiner in the United States Patent Office, died at his home in Washington on November 5th. Mr. McKee was the oldest examiner on the force, being in his eighteth year. He was a native of Hanover, Chautauqua County, New York, served in the Army of the Potomac during the civil War, and gained an enviable reputation as a teacher in the Washington public schools, being up to 1876 supervising principal of one of the prominent school districts. In 1885 he entered the Patent Office as an assistant examiner and for many years examined pneumatic and other door checks and hinges. While nearly eighty years of age, he did not seem an old man, having a bright, alert manner, a clear active intellect, and the appearance of being ten years under his real age. He was able to perform his duties in a most satisfactory manner up to his last illness of nearly three months. He was genial, kindly, possessed the ability to make and keep friends, was skillful in his business, and able to do a man's work to the end and will be greatly missed by the many who had business in his special classes of invention.

Notes for Inventors

Electric Lamp as a Bed Warmer.—John Alden of Boise, Idaho, has patented (No. 1,004,956) a bed warmer which includes a metal casing covered with asbestos so that it will not burn the feet of the sleeper and having an opening through which the heat from an electric lamp in the casing can escape to heat the bed.

Imitation Air Voyage.—In a patent (No. 1,005,961) Robert Macfarlane Murie of Invercargill, New Zealand, provides an apparatus for producing the illusion of traveling in an airship. The apparatus includes a dark room, a lift to support the passengers which is caused to move up, down and sideways in the dark room. A screen is arranged in front of the passengers and moving pictures are projected on the screen, the moving picture device and the lift being connected together so they will move in unison to heighten the illusion.

Combined Aeroplane and Parachute.—William A. Crawford-Frost of Baltimore, Md., has patented (No. 1,005,609) an airship improvement in which a supporting plane is provided with openings and a parachute folds upon the top of the plane to close the openings and opens upwardly to extended position to operate as a parachute when desired.



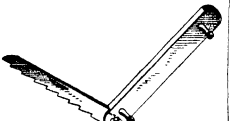
A Concrete Floor With Glass Blocks.—Henri L. J. Crochet, assignor, of Paris, France, has patented (No. 1,005,611) a readily removable paving block for reinforced concrete floors, which is of glass, and has an external thread and is formed in its inner end with a light recess which is adapted to receive a spanner so that the block can be conveniently turned when it is desired to remove it.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

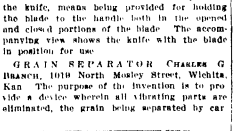
Electrical Devices.

AUTOMATIC SWITCH.—JOHN L. POLK, Memphis, Albany Co., N. Y. This automatic switch is for use in controlling electric currents, the switch in one of its movements being automatic, and also sluggish in its action. More particularly stated a switch is provided having a lever movable by hand in one direction and movable in the opposite direction by the action of a spring and against the cushioning pressure of a dash pot for the purpose of retarding the movement or rendering it sluggish, the idea being that when the switch lever is in one of its extreme positions it closes one electric circuit and a few moments afterward opens that circuit and automatically closes another. A plan view is shown herewith complete, the lever occupying its extreme position to the left and closing one of the circuits.



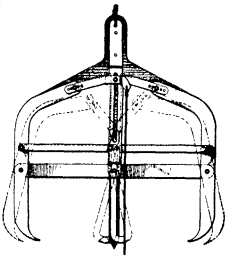
AUTOMATIC SWITCH

COLLAPSIBLE HANDLE CAN.—E. G. CASERA, Portico Vittorio Emanuele, 44, Genoa, Italy. This invention relates to metallic vessels and cans, the object being to produce an article at cheap price and easily carried by minimizing the space occupied in packing. These results are obtained by forming the mouthpiece for pouring the liquid contained in the vessel in the shell of the same and further by providing a yielding handle which, in packing, can be brought in contact with the body of the can, thus avoiding any projecting part.



Of Interest to Farmers.

FOLDING HAY KNIFE.—LUTHER L. CARR, Chalmers, Ind. The object in this improvement is to provide a novel construction of knife in which the blade can be conveniently folded into the handle so that when the knife is not in actual use the blade will be housed within and protected by the handle, the handle and the blade being so formed that the former operates as a stop to limit the opening movement of the blade at the proper point and the handle being provided with hand holds for convenience in manipulating the knife, means being provided for holding the blade to the handle both in the opened and closed portions of the blade. The accompanying view shows the knife with the blade in position for use.



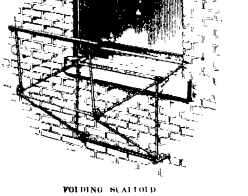
FOLDING HAY KNIFE.

GRAIN SEPARATOR.—CHARLES G. HEARCH, 1010 North Mosley Street, Wichita, Kan. The purpose of the invention is to provide a device wherein all vibrating parts are eliminated, the grain being separated by carriers and the like, thus dispensing with noise, and eliminating the great strain on the mechanism of vibrating or reciprocating parts. A vertical longitudinal section is shown in the engraving. The toothed wheels are very necessary since they thoroughly beat and shake up the straw so that the grain drops out of the straw. Screens and wheels work to secure cleaning action, thoroughly separating grain and straw, so that only a small portion of grain is passed out through the stack.

GRAIN SEPARATOR.

BALE CARRIER.—EDWARD H. BOEHME, R. F. D. No. 2, Rankin, Ill. A front presentation of a bale carrier patented by Mr. Boehme illustrates this article, and the inventor's object is to provide a simple inexpensive and easily operated fork especially designed and adapted for lifting material, such as hay, straw, and the like, in bales, which will firmly hold during elevation and transportation a plurality of bales, and which may be easily and quickly engaged with and released from the bales. The levers cannot be disengaged until the trip rope is pulled.

BALE CARRIER



Of General Interest.

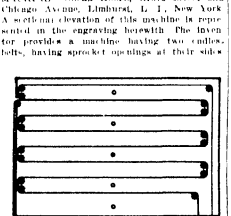
HOD STAND.—SAMUEL H. MOORE, Phoenix, Ariz. This invention is an improvement in hod stands for use in holding hods for carrying brick or mortar, and the invention has for an object the provision of a novel construction of folding hod stand which can be adjusted to suit any size of mortar or brick hod and hold such hod when applied to the stand at any desired angle. In practice the stand may be made of wrought iron of suitable size and dimensions to give the necessary strength for supporting the hod and the device will be found useful for the purpose for which it is designed. The engraving shows a perspective view of the stand as in use, the hod being in position.

HOD STAND

FOLDING SCAFFOLD.—F. ZAHN, Rhodesia Park, Norwalk, Conn. Mr. Zahn's invention relates to folding scaffolds for general use, his more particular purpose being to provide a simple, strong and efficient scaffold suitable upon the exterior faces of building walls and

FOLDING SCAFFOLD

adapted to be let out and drawn through windows or the like In order to erect the scaffold a shown in the accompanying illustration the device is let out through the window, so that the window bar lodges against the inner face of the wall upon opposite sides of the window To take the platform within the building the floor consisting of boards (shown in dotted lines) is first removed and taken inside the bar at the top is next grasped and pulled over practically through the window

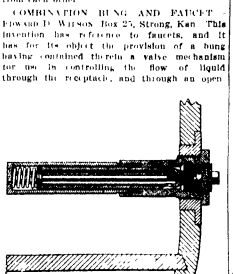


Household Utilities.

MEAT COOKER A Reubold, 1120 Fox Street Bronx New York, N Y This invention provides an airtight receptacle in which food meat is placed, and means for closing this receptacle so that juices and volatile parts of the meat will be retained, thereby preserving the flavor preventing shrinkage and increasing its value as an article of food, the use for which the device is best adapted being the cooking of bone hams and pork shoulders, so as to preserve their flavor, juices and aroma

Machines and Mechanical Devices.

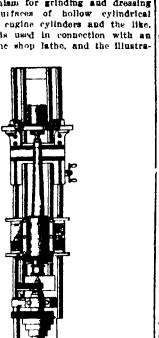
VALVE—I D Robertson, 210 South Seeley Street Chicago, Ill In this case the valve head is of thimble form and fits over and is secured to a cylindrical stem filled with buoyant material, as cork, to float the valve in water The valve is movably confined and guided in a cage and means provide to limit the drop of the valve from its seat It is especially designed for tanks to prevent overflow of water, without interfering with the circulation of air and steam the valve obviously rising and being forced tight to its seat by the rise of the liquid level



BLUE PRINT WASHING AND DRYING MACHINE.—Oscar Hoops, Grove Street and Chicago Avenue, Elmhurst, L I, New York A sectional elevation of this machine is represented in the engraving herewith The invention provides a machine having two endless belts, having sprocket openings at their sides

BLUE PRINT WASHING AND DRYING MACHINE.

which are disposed against each other, and which run over rollers with sprocket teeth journaled in a casing containing tanks and a compartment for respectively washing and drying the blue prints The prints are conveyed between the belts through the machine, and are introduced and removed at points outside the casing where the belts are spaced from each other

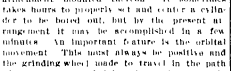


COMBINATION BUNG AND FAUCET—Howard D Wilson, Box 25, Strong, Kan This invention has reference to faucets, and it has for its object the provision of a bung having combined therein a valve mechanism for use in controlling the flow of liquid through the receptacle, and through an open

COMBINATION BUNG AND FAUCET

ing in the side of which the bung is disposed, so that when the plug is removed from the bung the valve is in position for use The accompanying illustration gives a view in sectional elevation showing the device attached to the side of a barrel The bung is made in two sections, so that the valve member may be readily disposed in position.

CYLINDER GRINDING MACHINE.—Edmond Stone and William Stone, 3510 South Wood Street, Chicago, Ill This invention relates to mechanism for grinding and dressing the interior surfaces of hollow cylindrical bodies, such as engine cylinders and the like. The invention is used in connection with an ordinary machine shop lathe, and the illustra-

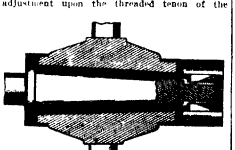


CYLINDER GRINDING MACHINE

tion shows a plan of the lathe having the attachment mounted thereon It sometimes takes hours to properly set and center a cylinder to be bored out, but by the present arrangement it may be accomplished in a few minutes An important feature is the orbital movement This noted always be positive and the grinding wheel made to travel in the path of a true circle and doing the work accurately with all mechanical precision

Railways and Their Accessories.

CROSS TIE—William E Jones, Chase Mills, N Y The object here is to provide a durable cross tie intended to replace the ordinary wooden tie now generally used, which can be employed with railroad track rails and the like, with which ordinary rail-holding means such as spikes, chairs and braces now



CROSS TIE.

generally employed can be used, which tends to prevent spreading of the rails, by means of which one on the other of the rails can be raised or lowered as necessary, which can be employed on straight track sections as well as on curves, and the employment of which permits the tracks to be easily and expeditiously laid and repaired The engraving herewith gives a plan view which shows the tie used to support a pair of track rails.

Pertaining to Vehicles.

HUB ATTACHING DEVICE—Jefferson D Robertson, La Plata, Md This improvement is in hub attaching devices for use on vehicle wheels and the like and has for an object to provide a novel construction by which the went on the ends of the box fitted upon the spindle may be easily taken up and by which the nut may be adjusted to take up this wear and may be locked in any described adjustment upon the threaded tenon of the

HUB ATTACHING DEVICE.

spindle and in which the locking devices for the nut may be released by moving the same longitudinally in the direction of the axis of the spindle There is a locking ball for the hub securing nut which ball has a cross bar extending radially across the outer end of the nut in position to be grasped in pulling the ball to unlock the nut The engraving shows a sectional view of the device as in use.

Note—Copies of any of these patents will be furnished by the Scientific American for ten cents each Please state the name of the patentee title of the invention, and date of this paper

NEW BOOKS, ETC.

Historical Atlas. By William Shepherd. New York. Henry Holt & Co., 1911. 8vo.; 216 maps, 94 pages of text. Price, $2.50.

This is one of the most valuable atlases that has come to the reviewer's table in a very long time In the first place, the data for the maps have been compiled in a most scholarly way by an expert, also with the advice and assistance of a splendid list of geographers and historians In the second place, the maps, which, by the way, were printed in Germany, are magnificent examples of the cartographer's art The combination of colors which are apt to be so very crude in atlases of American origin are toned down and admirably contrasted It is very difficult to call attention to any salient feature of this book, as it is of uniform excellence. Among the very interesting maps, however, are those showing the various Routes of the Crusaders, the Ecclesiastical Maps of Europe; the very interesting map showing the routes of the Mediaval Commerce; the Seats of the Medieval universities; the Medieval Commerce of Asia; Plan of a Medieval manor; the Age of Discovery, the Principal Seats of War in Europe in all Centuries, the Growth of Russia; Napoleon's Campaigns, the Unification of Germany, the Balkan Peninsula, the Commonwealth of Australia, the Partition of Africa, the Distribution of the Principal European Languages; the Colonies, Dependencies, and Trade Routes, Localities in Western Europe Connected with American History, Localities in England Connected with American History; the Indians in the United States; the New England Colonies, Campaigns in the American Revolution, Territorial Expansion of the United States, Organization of Territories; Slavery and Emancipation in the United States, Westward Development of the United States, and lastly, the Panama Canal It would indeed be ungracious to offer any criticism of this splendid work, but it is suggested that the 208th map, showing the seat of the Civil War, might have been made a two-page map to greater advantage, as a map of this kind is very much needed

To Mother. By Marjorie Benton Cooke. Chicago Forbes & Co., 1911. Price, 50 cents

It is seldom that one can whole-heartedly indorse present day poetry such as this The mother-theme, too, must be well handled not to be made ridiculous by distortion of values on the one hand, or by a cheap verbosity unsuited to meter on the other This being so, we take the greater pleasure in acknowledging the sweet dignity and the repressed yet strong appeal of the author's lines Even in ending her sonnets with the rhyming couplet—a form now frowned upon—we believe she has selected the mode most effective with such a theme and treatment For all mothers, and for all children of mothers, this little gift book must strike a true and uplifting chord.

The Hindu-Arabic Numerals By David Eugene Smith and Louis Charles Karpinski Boston Ginn & Co, 1911 8vo, 160 pp Price, $1 25.

Of all the numerous published monographs on our subject, none can be said to present a complete history of their origin, adoption, and adaptation The libraries of Europe and America have been searched in pursuit of the information embodied in "The Hindu Arabic Numerals," and all available evidence has been carefully weighed and passed upon The result is a reliable and fairly comprehensive review of the subject, from what is known of the origin of the characters, the earlier use of the place value, and the introduction of the zero, to the development of the system by the Arabs and its spread over the face of Europe When we consider that this system has been in general use for not four centuries, and when we realize the amazing clumsiness of the Roman characters which it displaced, we must approach its history with an enhanced respect and with an increased gratitude for what the system has done for our civilization

Text-Book of Mechanics By Louis A. Martin, Jr Vol III Mechanics of Materials New York John Wiley & Sons, 1911 12mo, 229 pp. Price, $1.50 net.

The author gives us a text-book of mechanics, designed for colleges and technical schools, in four volumes. "Statics" and "Kinematics and Kinetics" have preceded this, while "Applied Mechanics" is in preparation. The aim of the series is such an arrangement and presentation of its subjects as will encourage the student to reason as well as to memorise—to prove for himself, instead of simply accepting statements and solutions. The various stresses and strains are classified and explained in this third volume, and diagrammatic sketches and notations lead naturally up to the appended exercises and examples. The answers to the interpolated problems are given together at the back of the book, and there are between forty and fifty review problems given with the object of refreshing the memory and fixing principles indelibly in the mind.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12565) L. G. asks: Kindly inform me if rocks, stones, and boulders grow as they lie and are in the earth A. Rocks such as boulders do not increase in size as they lie upon the earth or buried in it. Layers of rocks have formed from their materials being pressed together under the ground by the weight of the earth above them in the long ages of the past.

(12566) A. G. asks: I am ashamed to ask you, but can you tell me the speed at which air at 60 degrees and 15 pounds would rush into a perfect vacuum? I cannot find the information in two encyclopedias nor two books on physics. A. You need not be ashamed to ask at what velocity air will rush into a vacuum, since no one can answer it. Air at 15 pounds pressure rushing into a place where there is no pressure will at that instant have an infinite velocity, the ratio of 15 to 0 From that instant the velocity will diminish until the pressure inside is equal to that outside, and the velocity will then become zero Between these two velocities there will be all possible velocities. No single velocity can be given. The 60 degrees does not affect the result If any text-book or encyclopedia will give a single velocity for this case, it would have to be marked "interesting, if true"

(12567) C A. P asks: Please answer the following in your column for queries: Does the top of a wagon wheel travel faster than the bottom? Please give explanation. A. The top of a wagon wheel travels along the road with the same speed as the wagon to which it is attached, else it would come off the wagon and go into the ditch. All parts of the wheel also rotate around the axle with the same speed, else the wheel would break into pieces. Lastly, the motion of a wheel may be referred to the ground even while it moves. It will then be found to have a very complex motion Mark a spot on the felloe with a chalk mark, so that you can see just where it goes with reference to the ground. As the wheel rolls along, the chalk mark coming down to the ground, is in contact with a point on the ground for an instant, and rises again till it is at the top of the wheel, and this it does every time the wheel moves as far as its own circumference When the mark is half way down from the top it is in front of the hub, and when it is half way up again it is behind the hub It has gone back the whole diameter of the wheel, just as it went up the whole diameter of the wheel It moves down and up, forward and backward, as it rolls around its hub, and moves along with the wagon as a whole The fact is, if the wheel does not slip, the mark stands still on the ground while it is in contact with the ground The fact also is that the mark at the top of the wheel moves forward twice as fast as the hub moves The mark moves backward, as seen from the wagon, from the time it is on the level of the hub moving down till it is on the level of the hub going up, and forward during the rest of its rotation. If you would see the actual path of a point in the circumference of a rolling wheel, take a circular piece of board and fasten a crayon into a hole at the edge; then roll the board along the chalk trough on a school blackboard in such a way that the crayon may trace its path on the blackboard. You will have the curve described by the point of the wheel along a vertical surface, just as the wheel traced its curve in the air. This curve is called in mathematics a cycloid. You will doubtless find a picture of it in any large dictionary. This matter seems to make a great deal of discussion We are obliged to print the explanation very frequently.

(12568) J S K asks: I am curious to know why, if the secondary terminals of a transformer are open, there is no apparent flow of current in the primary windings. For instance, take a bell-ringing transformer designed to work on 110-volt alternating current at 60 cycles and to step the current down to 6 volts. If the secondary terminals were open we detected no current flowing through the primary, but when the secondary was closed our instrument showed a flow of current in the primary. If you can give me the reason for this in the columns of your paper I will be under obligations to you. A. When the secondary circuit of a static transformer is open it is perfectly idle, no current is flowing through it, and no inductance exists between the primary and the secondary. In this case the primary acts simply as a choke coil, and the inductance of the primary upon itself cuts the current in the primary down to a small value. In your little bell-ringing transformer it is too small for your instrument to detect.

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN

New Practical Books

Popular Hand Book for Cement and Concrete Users

By MYRON H. LEWIS, C. E., and ALBERT H. CHANDLER, C. E. Octavo, 430 pages, 126 illustrations. Price, $3.50.

¶ A concise and comprehensive treatise on the principles and methods employed in the manufacture and use of concrete and its products in all classes of modern works. It is a standard work of reference covering the various uses of concrete both plain and reinforced. Everything of value to the concrete user is given, including kinds of cement employed in construction, concrete architecture, inspection and testing, waterproofing, coloring and painting, rules, tables, working and cost data. It is a thoroughly practical work, clearly written, systematic and logical in its arrangement, broad in its scope and gives a lucid explanation of, and a clear insight into the fundamental principles employed in concrete design and construction. The practical value of the book is enhanced by over thirty-five useful tables, and concise statements of rules and methods.

Drop Forging, Die Sinking and Machine Forming of Steel

By JOSEPH V. WOODWORTH, author of "Dies, Their Construction and Use," "Punches, Dies and Tools for Manufacturing in Presses," etc. Octavo, 340 pages, 300 Illustrations. Price, $3.50.

¶ A complete practical treatise on the hot and cold machine forming of steel and iron into finished shapes, together with the tools, dies and machinery involved in the manufacture of duplicate forgings and interchangeable hot and cold pressed parts from bar and sheet metal. It is a comprehensive and modern work, written by an expert, and treating fully on modern shop practice, processes, methods, machines, tools and details.

Any of these books will be sent, postpaid, on receipt of advertised price

If the Sun Were Suddenly Extinguished

To the Editor of SCIENTIFIC AMERICAN

Probably many readers of the SCIENTIFIC AMERICAN have wondered what phenomenon would appear were the sun to be annihilated instantly. Many, I suppose, thought that the light would be shut off immediately.

With the following explanation and accompanying diagrams I shall attempt to show what the result would be.

The diameter of the sun is known to be roughly 866,000 miles, and the speed of light to be 186,000 miles per second. Now, while the light of the sun appears to come from a disk, it really comes from a curved surface, the center of

which is nearly 433,000 miles nearer us than the edges. Let *A*, *A'* be the visible portion of the sun. (The figure is a cross section.) Then the light from the point *B* has a shorter distance to travel to the surface of the earth by 433,000 miles, or more than 2.3 *light seconds*. Therefore, the light from *B* reaches the surface of the earth 2.3+ seconds before the light from *A*, *A'*.

Now, supposing the light all over the sun should cease instantly. The light from *B* would stop 2.3+ seconds *sooner* than the light from *A*, *A'*.

Therefore, if the sun were suddenly annihilated, if one were observing at the time, about eight minutes (the time light takes to travel from the sun to the earth) after the sun would appear black at the center, gradually increasing, until 2.3+ seconds after the sun began to grow black, it would be entirely invisible.

Viola, Idaho. K. M. ADAMS.

Why do Not Human Eyes Shine at Night?

To the Editor of SCIENTIFIC AMERICAN

When hunting at night, one can see the eyes of animals shine pale green or red, when artificial light is directed on them; the same is seen when motoring at night with sheep, cattle, dogs, cats, etc. But this is never seen with human eyes. Why is it? The eyes seem to be made exactly alike. I think the above subject has never before been discussed, in fact, when I speak to anyone about it they say they have not noticed it. WALTER WYMANS.

Surrenden Park, Pluckley, Kent.

[Your question "Why do Not Human Eyes Shine at Night?" is not difficult to answer. The coat of the eye which carries the blood vessels, otherwise known as the *choroid coat*, is locally differentiated into a structure called the *tapetum*. This tapetum, situated on the back portion of the choroid coat, varies widely in different animals, both in appearance and detail of structure.

In the cat the tapetum, formed by a layer of cells containing crystals, is of a brilliant blue or green color, and it is the reflection and incident iridescence of light falling on this area that causes the eye to "shine" in the so-called dark.

I have kept a cat's eye preserved in

No Skidding
No Rim-Cutting
10% Oversize

Note the Double-Thick Tread
Note the Deep-Cut Blocks
Note the Countless Edges and Angles
Here's Your Ideal Non-Skid Tread

Over 700,000 Sold

When you go to buy tires, please consider these facts about Goodyear No-Rim-Cut tires.

The demand for those tires, in the past two years, has increased by 500 per cent.

That demand has compelled us to increase our capacity to 3,800 tires daily.

Over 700,000 have been sold to date. As a result of their use—on tens of thousands of cars—these tires now outsell any other tires in existence.

These are the tires you are bound to buy when you know the facts about them.

Millions Saved

No-Rim-Cut tires won their amazing prestige by cutting tire bills in two. They have saved motor car owners many millions of dollars.

These tires are the final result of 13 years spent in tire making. Men can never make tires any better.

Then, our patented features make these tires proof against rim-cutting. With the ordinary tires—with clincher tires—23 per cent of all ruined tires are rim-cut. A punctured tire may be wrecked in a single block.

Out of 700,000 of these patented tires, not one has ever rim-cut. That worry and expense is forever avoided.

Then, No-Rim-Cut tires are 10 per cent oversize. That is due to the fact of the boookless base. These tires are not hooked to the rims.

That means 10 per cent more air—10 per cent greater carrying capacity. And that, with the average car, adds 25 per cent to the tire mileage.

With these tires you save rim-cutting. You save the blowouts due to overloading. You get extra capacity without extra cost. For those patented tires now cost no more than other standard tires.

The result of this is, under average conditions, to cut tire cost one-half.

Now Double-Thick Non-Skid Treads

Now we have added, for those who want it, a double-thick Non-Skid tread.

Not any mere makeshift—not a flimsy, short-lived protection. This is an extra tread, about as thick as our regular, vulcanized onto the regular tread.

This extra thickness permits of deep-cut blocks. Those blocks are made of immensely tough rubber. They present to the road surface countless edges and angles. And they don't soon wear down.

Danger of puncture is reduced 30 per cent by this double tread.

Each block widens out at the base, so the strain is distributed over just as much surface as with a smooth-tread tire.

Those are some of the dozen advantages over any other non-skid tread.

No-Rim-Cut tires with this Non-Skid tread put an end to rim-cutting, an end to skidding and an end to overloading. And those are the three greatest tire troubles.

GOODYEAR
No-Rim-Cut Tires
With or Without Non-Skid Treads

Our Tire Book, based on 13 years of tire making, is filled with facts you should know. Ask us to mail it to you.

Big profits in this Little Engine for you

This is Tom Thumb—one of the famous engines in the I H C line

Tom Thumb develops more than one-horse power. In the shop it will operate a lathe, drill-press, emery grinder or other small machines. It is powerful enough to pump all the water needed on the ordinary farm—will run the cream separator, grindstone, bone cutter, churn, small corn sheller, washing machine, etc.

This little work saver is exceptionally simple and strong and will give steady economical power for years. It is an I H C through and through. It is made of the same high grade materials and is built and tested in the thorough manner that distinguishes all

I H C Gasoline Engines

Tom Thumb comes all complete, including governor, spark plug, batteries, tools, etc. No water tank is needed. The cooling is done by air

Write for more information about I H C engines. They are made in many styles and sizes for every need 1 to 50-horse power, stationary or portable; air or water cooled; built to operate on gas, gasoline, kerosene, distillate or alcohol. Also gasoline and kerosene tractors, 12 to 45 horse power. Write now for catalogue and any special information you desire. Address:

International Harvester Company of America
(Incorporated)

A Home Made Alternating Current Motor

¶ Read *Supplement 1688* for a good, clear article by F. E. Ward, E. E., on the making of a one-eighth horse power alternating current motor. The motor can be constructed by anyone of ordinary skill in the use of tools who has access to a screw-cutting lathe with a swing of nine inches or more. The motor is designed to run on the 100 to 120 volt, 60-cycle, single-phase alternating current circuit, now in wide-spread use for the lighting of dwellings. The motor will drive a 16-inch brass fan, a small lathe, or a 50-watt dynamo for generating direct current for charging storage batteries, and in fact will do almost any kind of work that can be done by one-man power. Order from your newsdealer or from us.

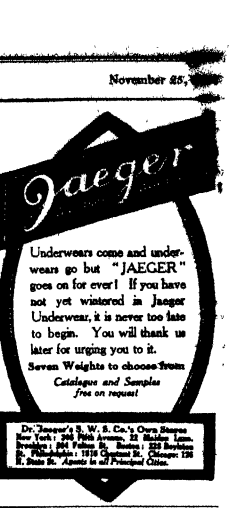
glycerin jelly for five years, which still shows undiminished iridescence when a ray of light is allowed to fall upon its tapetum. The eye of a horse kept for a like period gives the same result.

In man the tapetum is insignificant, and therefore the phenomenon of "shining" at night is not observed. Between the tapetum of man and that of the cat we find all grades of development in the other mammals, and a critical examination will show that the degree of "shining" in the dark will vary according to this development. R. W. Tower, Curator of Physiology, American Museum of Natural History, New York.]

Association of Variable Star Observers

To the Editor of Scientific American:

Notice is hereby given that an association of variable star observers has recently been organized in this country. All those interested in astronomy possessing telescopes of three inches aperture or larger are cordially invited to co-operate in this work. This plan has received the indorsement of Prof. E. C. Pickering, director of the Harvard College Observatory, and monthly reports of the work of this association are sent to the Harvard Observatory. Here is an excellent opportunity for observers to render science practical aid, and use their telescopes to good advantage. The work is not difficult, involves no mathematics, and requires no experience. Those desiring further information respecting this line of observation work are requested to address



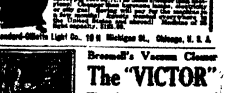
William Tyler Olcott.

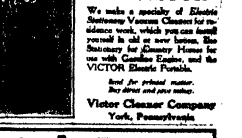
Norwich, Conn

Zeppelin's "Schwaben"

(Concluded from page 478.)

honored aeroplane rudders, fore and aft, were removed—quite a revolutionary step, because they had always proved efficient. Only one set of them was now attached to a more graceful single rudder frame at the extreme rear, where they were combined with vertical rudders and cleverly supported by the stabilizing fins. It was found that thus friction and head resistance was cut down, steadiness improved and the efficiency of all rudders wonderfully increased, for the big ship could now be turned completely within a circle of only 1,600 feet in diameter. It was surprising that the lifting power of the ship suffered nothing from the removal of its "aeroplanes;" the kite effect of the smooth cylindrical hull so well replaced theirs that instead of falling below the floating power of the "Deutschland," that of the "Schwaben" was essentially increased by her greater speed. The efficiency of an aeroplane which is very long in its line of motion is improved in a dirigible by the small weight it has to carry dynamically per square foot of its immense surface. Incessant experimenting with propellers is going on in the Zeppelin laboratory, and the "Schwaben's" large four- and two-bladed ones showed increased efficiency. The brackets holding them were cleverly robbed of much head resistance and turned into useful and ornamental steadying fins by a cloth covering. Structural strength was increased at the essential points. The cars and the cabin were built of corrugated aluminium. The size and strength of the pneumatic buffers under the cars was increased. The success of the "Schwaben's" many passenger trips is not only due to her own greater power, but also to perfected methods of handling rigid dirigibles. There are mechanical docking devices in the new sheds which hold the ship securely until it is safe in the open air, so that it may enter and leave without danger. A rail on each side of the shed runs far out into the open through each of the doors at both ends. Each length of rail is made of two narrow channel plates, rivetted together back to back. Two sets of rollers run on each rail, each set bearing against the underside of the upper flanges. Four steel cables depending from the airship's frame can be made fast to the four sets of rollers and may all be slipped simultaneously. The two rails are so far apart that a dirigible lashed to them cannot be swayed if it has sufficient lift, and this may be obtained by removing passengers and bal-





ROTARY PUMPS AND ENGINES

Their Origin and Development

An important series of papers giving a historical resume of the rotary pump and engine from 1588 and illustrated with clear drawings showing the construction of various forms of pumps and engines. 20 illustrations. Bring us your Waterproofing and Finishing Problems

With our complete line of Waterproofing Products, Dampproofing Compounds, Scientific and Technical Paint Products, we are in best position to solve your problems.

All walls coated with Trus-Con Stone-Tex

TRUS-CON STONETEX

A liquid cement coating for stucco, concrete and brick,—applied with a brush. Uniform in color results. Absolutely dampproof. Weather resisting. Does not chip off, crack or peel like paint. Becomes an inseparable part of the wall, sealing all pores and filling hair cracks, giving an artistic flat finish as hard as flint.

Walls and Ceilings Finished with ASEPTICOTE Woodwork and Mantel, Finished with SNO-WITE

TRUS-CON ASEPTICOTE

A flat, washable, durable, sanitary, decorative finish for interior walls. Perfectly aseptic and sanitary. Easily cleansed with soap and water. Most artistic in appearance. Manufactured in great variety of tints. Applied on interior surfaces of plaster, cement, brick, wood, burlap and metal.

TRUS-CON SNO-WITE

An enamel of the very highest quality for finishing interior surfaces of wood, metal, plaster and masonry. Produces a finish with a delicacy of tone, softness, whiteness and luster that cannot be excelled.

TRUS-CON INDUSTRIAL ENAMEL

A gloss coating of whitest white, with powerful light-reflecting qualities, for treating factories, work-rooms, enclosed light shafts, etc.

TRUS-CON FLOOR ENAMEL

Produces a tough, elastic and reasonably durable finish on all cement floors, rendering them washable, stainproof, oilproof and dustless.

Trus-Con Waterproofing Paste, integral waterproofing for concrete.

Trus-Con Plaster Bond, a damp resisting paint for interior of exposed walls.

Trus-Con Por-Seal, a transparent coating for dampproofing exterior masonry.

Trus-Con Edelweiss, a durable artistic enamel for exterior surfaces.

Trus-Con Dairy Enamel, durable, sanitary enamel for dairies and creameries.

Trus-Con Laboratory Enamel, to resist chemical gases in laboratories.

Trus-Con Bar-Ox, most advanced protective coating for iron and steel.

Consult us at this time regarding your present Waterproofing and finishing problems. We can help you. Let us send you our literature.

Trussed Concrete Steel Co.
Trussed Concrete Bldg., Detroit, Mich.

last during the time that the airship is pushed in or out of its shed. Starting a flight means simply to take aboard passengers and ballast after the ship is at a safe distance from the menacing walls of the shed, and instantly to release all the hawsers But entering the shed with a brisk wind blowing at right angles to its axis and to the rails is more difficult. In this case the ship is halted in the open over the track, pointing into the wind. One of the front cables is fastened to the rollers nearer the shed on the windward rail. With this set of rollers as a fulcrum the ship is worked around by pulling at the rear end, steadying it along the sides, and simultaneously pulling the lee side down, until it becomes parallel to the rails It is then a simple matter to fasten the remaining cables, unship passengers and ballast, and roll the ship as safely into the shed as though it were a train of railroad cars

It may be worth noticing that this device is the same, though more primitive and still depending on the co-operation of a great number of men, as the one suggested in the SCIENTIFIC AMERICAN directly after the accident to the "Deutschland II."

Of equal importance to the docking of these big ships is their safe anchoring where there are no sheds. A safe anchorage over unobstructed grounds, mostly parade grounds, has now been prepared near almost every German city The holding device is a development of the method by which in the past severe squalls occasionally have been weathered It is different in so far that the pivotal point around which the ship freely swings into the wind's direction is now not on the ground but in the ship's own frame Even with the short single bow cable formerly used successfully, jerks which strained the frame and the cable were not entirely avoided in gusty winds (Too much play for the bow In the accident at Limburg snapped the long cable and freed the ship, though it did not damage the frame)

In place of one cable there are now four, giving greater safety They are part of the ship, and may be seen hanging from the bow They are fastened to a ring that pivots around a strong pin in the reinforced framework To anchor the ship, they are made fast with their free ends to four heavy cubes of concrete, each 3¼ feet in diameter, sunk into the ground, and so arranged that the four cables evenly radiate toward them from their pivot on the bow. Thanks to its rigidity, the ship now turns around the apex of this pyramid of cables, as smoothly as a new weather vane around a steeple Unshipping ballast at the bow makes this pyramid very rigid.

Weather "Kiosks" at Home and Abroad

(Concluded from page 477.)

maximum and minimum thermometers set, etc., by an employee of the local Weather Bureau station

As a substitute for the ill-exposed and often ill-constructed drug-store thermometer the kiosk amply justifies its existence in providing an accurate record of the conditions to which the urban population is exposed In hot weather the thermometers in the kiosk read many degrees higher than those of the regular Weather Bureau station. The following comparison of maximum readings during a summer hot spell at Washington is instructive:

July, 1911.	Weather Bureau Observatory	Kiosk.
	Degrees Fahrenheit	Degrees Fahrenheit
3	97.7	106.0
5	99.1	106.5
4	96.7	106.0
5	97.8	104.5
6	98.3	108.5
7	95.0	102.7
8	84.2	93.5

When a brisk wind is blowing the difference between observatory and kiosk temperatures is less than shown by the above comparison. The propriety of artificially ventilating the kiosk—the plan adopted in a type of kiosk used in Germany, as described below—has been con-

Why Nelson's Is Known As The Perfect Encyclopaedia

There Are Four Conclusive and Common Sense Reasons:

"It Cannot Grow Old"

Reg. U. S. Pat. Office

That Little Bar and Nut has solved the Problem! It has put all other Encyclopaedias out of date!

Bound in 12 Handsome Volumes

1. It Cannot Grow Old because our subscribers are furnished with at least 800 pages of new information each year—semi-annually, in March and October—which brings them up to the minute on all important events Those pages are properly numbered, and by simply turning a nut in our loose-leaf binding you can remove the obsolete pages, and insert the new. Your Encyclopaedia will be just as much up to date twenty years from now as it is today. **No other Encyclopaedia CAN possess this feature, as it is fully protected.**

2. Accuracy. There are three **permanent editorial staffs maintained** by Nelson's—one in the United States, one in Great Britain, and one in Canada—headed, as Editor in Chief, by John H. Finley, LL.D., President of the College of the City of New York These three great Editorial Staffs have gathered about them a corps of contributors who stand supreme as authorities in their respective subjects, and who, immediately any new information is available, forward a treatise to us to be included in our current supplementary pages. Nelson's is the only Encyclopaedia supporting more than one Editorial Staff.

3. Minute Details Available. All subscribers are given an unlimited membership in Nelson's Research Bureau. This facilities you in questions on any subject of the moment in which you may be especially interested, with the assurance that you will promptly receive the latest information and references to works which treat of that subject in minute detail Letters to us from the greatest educational and technical workers show this service to be invaluable It is only our unremitting search for fresh matter to supply our new pages that makes it possible for us to offer you this great service, without additional cost

4. Educational Features In addition to many special articles of the greatest instructive value, we have imported, especially for this Encyclopaedia, Books and Manikins which are wonderful in their detail and their simplicity. Such interesting subjects as the Human Body Automobile Turbine, etc., are so presented that even a child can understand and be instructed by them So other Reference Work possesses this important educational feature

Nelson's Perpetual Loose-Leaf Encyclopaedia

And Research Bureau for Special Information

Approved, adopted and used by U S Government Departments and by Universities, Colleges, Libraries and School Boards throughout the country Following are among the U S Departments and Colleges now using Nelson's:

Navy Department	Bureau of Corporations	Bureau of Chemistry	War Department
Department of Justice	National Museum Library	Army Service School	Weather Bureau
Commerce and Labor	University of Rochester	Reclamation Service	Knox College
Department of State	University of California	Chief Signal Office	Indian Bureau
Cornell University	University of Michigan	Harvard University	Etc , etc , etc.

Also the King of England, The Emperor of China, The Mikado of Japan, The Premier of Canada and State Departments throughout the world. Nelson a Perpetual Loose-Leaf Encyclopaedia contains more than 70,000 subjects—treating over 1,000,000 topics—7,000 illustrations—500 maps.

Each article in Nelson's is clear, concise in treatment, and embodies the results of the very latest scholarship and research. For example, articles on the Death of Edward VII and the Coronation of George V, of England; Flying Machines and Moon Railways, Dreadnoughts and Submarines Trusts and Cost of Living; Tunnels, Turbines, Steel and Iron Construction, Christian Science and Eyesight rapidly, Hookworm, Pellagra, Tuberculosis, Cancer The 1910 Census by the United States, England, Germany also **The Election of Madero; The Destruction of Austin, Pa.; The War Between Turkey and Italy**

Exchange—We are constantly receiving inquiries asking us to make an allowance for old encyclopaedias to apply as part payment on Nelson's We have therefore prepared a price list, stating the amount allowed which will be mailed upon request

Write today for the FREE loose leaf portfolio, containing Sample Pages, Facsimile Certificate of Membership in Nelson's Research Bureau, Specimen of Reference Service, Facsimile Letters from Scientists and Educators, and full information about Nelson's Loose Leaf Reference System Our special introductory price and easy payment terms interest all who appreciate a bargain

Here's a Christmas suggestion that is new

Also one that you will recognize at once as wonderfully pleasing and timely—

Can you imagine a more acceptable gift for a man than a Carborundum Razor Strop or a Carborundum Razor Hone with its remarkable sharpening qualities?—

Can you imagine a more appropriate gift for either man or women than a Carborundum octagonal, stag-handled knife sharpener—

Or for the sportsman, than a Carborundum sportsman's stone in handsome pigskin case with strap at the back for fastening to the belt?—

Carborundum is the most remarkable sharpening agent the world has ever known. It is intensely hard and sharp—practically crushed diamonds made into sharpening stones for every conceivable sharpening requirement from the honing of a razor to the sharpening of an axe.

Put up With Great Care in Handsome Holly Covered Boxes for the Christmas Season

and on sale at hardware stores the country over—If your dealer doesn't have them send direct—

Don't neglect this new and wonderfully appropriate Christmas offering

No. 79-F	Knife Sharpener, octagonal, solid stick of Carborundum stag handle in neat box,	$1 00
No. 78-F	Knife Sharpener as above with wooden handle,	50
No. 162-F	Carborundum Razor Hone—very fine and efficient in neat box,	1 00
No. 411-F	Carborundum razor strop—heavy weight, genuine selected horsehide, razor case handle, trimmed with brass open swivel hardware,	1 75
No. 131-F	Round Combination Stone for sportsman in leather case—strap for belt,	1 00

If New York Should Burn?

IF New York should burn, like Baltimore or San Francisco, it would bring financial disaster on this entire continent. New York today is considered by engineering and insurance authorities to be in fully as great danger of destruction by fire as were Baltimore and San Francisco before their fires came. The story of the conflagration danger in New York—which, considered as a whole, is growing worse from year to year—is told in a carefully prepared article by Arthur E. McFarlane in the December Number of

sidered. It is a question, however, whether the structure with this modification would answer so well the purpose for which it is intended; since the populace, whose environment the kiosk instruments are designed to gage, does not habitually carry an electric fan about the streets, nor even continually wield the palm-leaf in the busy round of daily occupations. On the other hand, neither is the populace inclosed in a cast-iron cage, and possibly finds itself more comfortable in hot weather than would the kiosk thermometers if they had human sensibilities; so that the question of artificially ventilating these structures may be regarded as an open one.

The meteorological kiosks of Europe, in contrast to those just described, are not maintained by the official meteorological services of the several countries Some have been erected by instrument-makers, as a means of displaying their wares; others are installed at health-resorts, as an attraction to visitors; but the majority are mere sign-boards for the display of miscellaneous advertisements, which occupy most of the surface space. The instruments being relegated to any odd corner that can be spared Their architecture varies according to the taste of the designer, without, as a rule, any regard to the proper exposure of the apparatus Some of these structures, especially those erected by the municipalities, are most imposing—to look at One built some twenty years ago by the city of Berlin cost 7,000 marks ($1,666) In this structure the instruments were installed behind glass in shallow unventilated panels, and in summer all of them were exposed during part of the day to direct sunshine The apparatus included a mercurial barometer hung at such an elevation that no one could read it without the aid of a step-ladder All the instruments were grossly neglected, and those that should have shown identical readings exhibited instead the most remarkable discrepancies.

Latterly, however, certain foreign instrument-makers, especially in Germany, have turned their attention to the production of kiosks satisfying scientific as well as popular and artistic requirements Probably the first German kiosks to be constructed according to scientific principles were those erected in Berlin about 1891 by the Urania Uhren- und Säulen-Gesellschaft, and known as "Uraniasäulen" (Fig 4) These were intended primarily for displaying advertisements, but contained well-constructed and well-exposed meteorological apparatus, ventilated by a clockwork-driven fan, according to the principle of the Assmann aspiration-psychrometer Unfortunately the Urania Company did not have a long career; the kiosks were bought by the municipality, and in most cases deprived of their instruments In a few, however, the instruments are still kept in operation.

Excellent weather kiosks are now manufactured in Germany, though one sees plenty of the opposite kind at the "Kurorte" and other frequented places in that country The type of kiosk constructed by R Fuess, of Steglitz, near Berlin, is shown in Fig 3 This contains a barograph, hygrograph, and thermograph, the pens of which trace their records on a sheet of paper wound around a single revolving drum The apparatus is ventilated, according to the Assmann method, by a revolving fan, driven by electricity or water-power—usually the latter Kiosks are also manufactured on a large scale by W. Lambrecht, of Göttingen (Fig 1) and usually house some of his special instruments; such as the "polymeter" and the "weather-telegraph." The latter comprises a particular form of hygrometer and an aneroid barometer, the dials of which stand side by side; while underneath is a series of diagrams which, it is claimed, enable one to forecast the weather from the indications of the two instruments.

BUSINESS OPPORTUNITIES.

WANTED PARTY to manufacture my multiple tube pneumatic tire for Automobiles and Bicycles, patented Oct. 7, 1911. A money maker. For further information address, Dr. Robert E. Kyner, Ft. Carbon, Pa.

WANTED FOR EXPORT—Rag-mill to feed for metal cleaning preparations, also Fuller's earth as used for toilet powdering. Please send price, capacity and full particulars. F. O. B., N. Y., Export, Box 773, N. Y.

INVENTORS—Send a copy of your patent to us and we will send you our business building out. Net three manufacturing plan. For further particulars address, Atlantic Supply Co., Long Branch, N. J.

BUSINESS OPPORTUNITY.—Wanted a partner to help manufacture and sell a newly patented automobile accessory. First class sales proposition. For further information address, T. F. Hutchings, 123 W. 3rd St., N. Y.

GOOD BOOK—Learn the great Palmer system of making name plates, beauty markers, signs, etc. Make $5 to $10 a day. Send for beautiful thirty-two page book—sixty-five illustrations. R. Palmer, Norwalk, Ohio.

FOR SALE.

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative in his locality. Whole or spare time. Previous experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or canvassing. This is an exceptional opportunity for a man in your locality to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address R. E. Harden, Vice-President and General Manager Real Estate Company, 1,100 Marden Building, Washington, D. C.

OLD COINS.

OLD COINS—$1.75 paid for rare date 1853 quarters. $75 for a 1804 silver dollar. We pay big premiums on many dates of coins from 1793 to 1895. Send 4c. at once for New Illustrated Coin Value Book, 4 x 7. It may pay you. Coin Exchange. Clark & Co., Coin Dealers, Box 48, Le Roy, N. Y.

PATENTS FOR SALE.

FOR SALE—Patent No. 993,856. Rear mechanism for clutches. Patent applied to passenger, but not confirmed, otherwise I would not sell. Address, Box 1,000, Sandy Lake, Mercer's working model. E. W. Reed, Lansdale, Pa.

PATENT FOR SALE, No. 993,714, Fire Escapes, issued Feb. 27, 1911, for sale or for manufacture on royalty from Victor J. Evans, Ishpeming, Mich. For further particulars write C. W. Zahnleuter, Negaunee, Mich.

REAL ESTATE.

TEXAS INVESTMENTS.—Buy farm unimproved garden lands near Houston, the greatest and most prosperous city in the south. Values will more than double in a few years. Write for list of bargains and my book on Texas real estate in short time. Many others have made money. Why not you? Address, personal letter, owner, Lindsey B. C. Robertson, 20 Rusk Bldg., Houston, Texas.

WANTED.

WANTED—One mechanical engineer at $2,400 per annum. A chemist at $1,800 per annum. Two draftsmen at $1,200 per annum. Two draftsmen at $1,000 per annum. Two draftsmen at $900 per annum. Two draftsmen at $720 per annum. Two draftsmen at $600 per annum. Two draftsmen at $480 per annum. Address, Box 773, New Haven, Conn.

economics laid down in such a course has the assurance of being in demand as long as this country remains a great industrial nation. In these days, when the industrial needs of the land are growing so rapidly, the demand for electrical engineering graduates who come from the best planned and administered engineering schools is very great, and, as long as the industrial growth of the nation continues, the demand will continue to absorb all well trained young men that the schools can supply.

An experienced engineer should have the ability to conceive, originate and direct extended industrial enterprises. To attain this ability requires many years of mature experience, and an electrical engineering course that is expected to promote the highest welfare of its graduates must be largely occupied with teaching the principles of science, i. e., the purport of known natural laws and their relations to each other. Young men with this sort of a training are not seasoned engineers, but they have the training which gives them great capacity for becoming engineers and after sufficient experience in actual practice of obtaining the highest rank consonant with their individual abilities. This great capacity for becoming efficient engineers through the seasoning effect of experience, which engineering graduates possess, is a sufficient reason for their being in demand. Such graduates have opportunities for professional usefulness in many branches of electrical engineering.

In telephony the work is primarily one of unending detail, but it may lead to broad and comprehensive executive duties in connection with one of the great servants of commerce, and the telephone service offers so many opportunities of benefiting the public that it has attracted a great many able men to its ranks. In electric railroading is found a rapidly growing branch of service that appeals to the imaginations of many. There are opportunities in it leading to executive duties in a branch of industry that composes the very backbone of commerce. With the present tendency toward electrification of the great terminals and mountain divisions of trunk line steam railroads and even of their main stems, the graduate of an electrical engineering course who goes into railroading with the firm purpose of learning the best processes of handling traffic has possibilities of a great career before him.

Similar attractions are found in electric light and electric power transmission and attractions of other kinds and unending variety are found in the manufacturing industries, but it should be remembered that most of the men capable of deserving the highest positions within the sphere of electrical engineering practice must expect to become either men of executive force or men who originate new projects or machines. In either of these vocations it will be found that far more than a trades education is needed and that the appropriate education must be, broadly speaking, the education of a gentleman, a man of the world, and a scientist. Such men find use for all of the scientific studies already named and also for the training in language, history and political science which has now come to an honored place in the curricula of a few of our engineering schools.

There is also at the present time a considerable call for competent teachers in electrical engineering courses, and the work of research in regard to electric and magnetic phenomena is growing rapidly and is calling for workers.

When the field of electrical engineering is examined in this manner, and the experience of the able young men who are now graduating year by year from the electrical engineering schools is compared, there can be no other conclusion reached than that electrical engineering as a profession offers opportunities for those who have industry and a taste for science and business which are not excelled in any profession or branch of business. Experience shows that there are opportunities in electrical engineering for all well trained young men who possess good sense and industrious habits, and particularly for those who have the ambition, capacity and industry to digest a course at one of those few schools which stand in the first rank of scientific accomplishment and earnest endeavor.

Physicians in Many Lands Advise—"Sanatogen"

His Excellency Prof. Dr. Von Leyden
Director Royal Medical Clinic, Berlin University, writes:
"I have gladly and frequently prescribed Sanatogen in cases of delicate patients in my clinical as well as in my private practice and am extremely satisfied with the results."

Late King Edward's Physician, Dr. Ernest Ott writes:
"I have been using Sanatogen for a number of years in my practice with excellent results. Those results have been notably good in the case of elderly people when it was desirable to build up the strength, to stimulate the bodily functions, and to improve the circulation of the blood."

Prof. C. A. Ewald
Of Berlin University, Director Kaiserin Auguste Victoria Hospital, Medical School, Berlin, writes:
"I can say that I have used Sanatogen in a great number of cases (that is, in those disturbances of metabolism which were mainly of a nervous or neurasthenic origin) and have obtained excellent results."

Prof. Thomas B. Stillman, M.S., Ph.D.
The well known research chemist of Stevens Institute, writes:
"The chemical union of the constituents of Sanatogen is a true one, representative of the highest skill in the formation of a product containing phosphorus in the organic phosphate condition, and so combined that digestion and assimilation of the nutrients are rendered complete with the greatest ease."

ILL HEALTH has no nationality and science has no geographic boundaries.

When 15,000 physicians (in Germany, England, America and elsewhere) endorse Sanatogen over their own signatures—when 120 articles in leading medical journals of these countries extol the virtues of this remarkable food-tonic—there can be no exaggeration in calling Sanatogen an international scientific triumph.

Wherever the movement of civilization is swiftest the toll on the nervous system is greatest—and no nation escapes the toll. The remarkable fact that Sanatogen is today the most popular international food-tonic shows first the *need* of it; second its splendid ability to *meet* that need.

Sanatogen, the food-tonic, speaks in the universal language of the human system. To the cry of tired nerves it answers in a way the nerves understand—its elements are the very elements of human strength. Its pure albumen and sodium glycero-phosphate, scientifically combined, *restore* to nerves and cells and tissues the elements taken from them by the drain of overwork and worry. Its vitalizing, nourishing, upbuilding action gladdens every fibre of the system, helps to give back to man his dominion over his body.

Noted men of many nations join with the exponents of science in acknowledging the unique powers of Sanatogen—for it is by *results* that Sanatogen has earned its undoubted pre-eminence.

Do *you* need upbuilding? If you do, you need Sanatogen.

Sanatogen is sold by all leading druggists at $1.00, $1.90 and $3.60

Write for a FREE copy of "Our Nerves of Tomorrow"

The work of a physician-author, written in an absorbingly interesting style, beautifully illustrated, and containing facts and information of vital interest to you. This book also contains evidence of the value of Sanatogen which is as remarkable as it is conclusive.

Get Sanatogen from your druggist—if not obtainable from him, send upon receipt of price

JUST PUBLISHED *A New and Authoritative Book*

MONOPLANES and BIPLANES

THEIR DESIGN, CONSTRUCTION & OPERATION

The Application of Aerodynamic Theory, with a Complete Description and Comparison of the Notable Types

By GROVER CLEVELAND LOENING, B Sc., A M.

Aviation is a predominant topic in the mind of the public, and is rapidly becoming one of the greatest goals of development of the progressive engineering and scientific world. In the many books that have already been written on aviation, this fascinating subject has been handled largely, either in a very "popular" and more or less incomplete manner, or in an atmosphere of mathematical theory that puzzles beginners, and is often of little value to aviators themselves.

There is, consequently, a wide demand for a practical book on the subject—a book treating of the theory only in its direct relation to actual aeroplane design and completely setting forth and discussing the prevailing practices in the construction and operation of these machines. "Monoplanes and Biplanes" is a new and authoritative work that deals with the subject in precisely this manner, and is invaluable to anyone interested in aviation.

Mr. Loening, who has come in intimate contact with many of the most noted aviators and constructors and who has made a profound study of the subject for years, is unusually well informed, and is widely recognized as an expert in this line. In a clear and definite style, and in a remarkably thorough and well-arranged manner he has presented the subject of aviation. The scientific exactness of the valuable data and references, as well as the high character of the innumerable illustrations and diagrams, renders this work easily the best and the most useful, practical and complete that has ever been contributed to the literature on aeroplanes.

Following is a table of the contents:

PART I
The Design of Aeroplanes

Chapter I. Introduction. II. The Resistance of the Air and the Pressure on Normal Planes. III. Flat Inclined Planes. IV. The Pressure on Curved Planes. V. The Frictional Resistance of Air. VI. The Center of Pressure on Flat and Curved Planes. VII. The Effect of Depth of Curvature and Aspect Ratio upon the Lift and Drift of Curved Planes. VIII. Numerical Example of the Design of an Aeroplane.

PART II
Detailed Descriptions of the Notable Aeroplanes

Chapter IX. Introduction. X. Important Types of Monoplanes. XI. Prominent Types of Biplanes.

PART III.
Comparison of Types

XII. Comparison of the Prominent Types. XIII. Controlling Apparatus. XIV. Accidents. XV. The Variable Surface Aeroplane. Index.

12mo (6x8¼ inches) 340 Pages, 278 Illustrations. Attractively bound in cloth.

Price $2.50 net, postpaid

An illustrated descriptive circular will be sent free on application.

THE YOUTH'S COMPANION
for 1912

IF YOUR FAMILY is worth the best you can give in house and food and clothes, is it not worth the best reading as well? And the best of reading—best for boy and girl, best for men, best for women—is contained in the pages of The Youth's Companion. : : : : : : :

READING which with all its power to entertain is a power also to benefit. Here is a handful out of hundreds of Companion contributions for 1912:

The Brotherhood of Boy Scouts	Lieut.-Gen. Baden-Powell
General Booth	William T. Stead
Humorous Incidents of the Gridiron	Walter Camp
When Jack Writes Home	Frank T. Bullen
The Exacting Daughter	Harriet Prescott Spofford
The Safety of the Ship	William H. Rideing
Axel Eriksson, the Great South African Hunter	Sir Harry Johnston
The Main Elements of Success	President Maclaurin of the Mass. Inst. of Technology
A Tribute to Dickens	Jerome K. Jerome
The Struggling Student in Scotland	Sir James Crichton-Browne
Student Ideals in Japan and America	President Pritchett of the Carnegie Foundation

Then there are the stories, nearly 300 of them—stories different from the common lot. Stories of pluck in adversity, coolness in peril. Stories of the sea and the waste places of the earth. Stories of life among the Indians. Stories of the Awakening of character. Droll sketches of domestic trials and shamefaces. You'll like them all. Send for our 1912 Announcement, free.

All Remaining 1911 Issues Free.

HOW TO GET THEM

EVERY NEW SUBSCRIBER who at once cuts out and sends this slip (or mentions this paper) with $1.75 for the 52 issues of The Youth's Companion for 1912 will receive Free

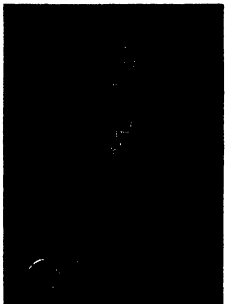
ALL THE ISSUES for the remaining weeks of 1911, including the Thanksgiving and Christmas Holiday Numbers; also Free

THE COMPANION PICTURE CALENDAR for 1912, lithographed in 12 colors and gold—an extra copy being sent to every one making a gift subscription.

THEN THE YOUTH'S COMPANION for the 52 weeks of 1912—all for $1.75. Your last chance to get The Youth's Companion at this price. On January 1, 1912, it will be advanced to $2.00.

BM127

THE YOUTH'S COMPANION, BOSTON, MASS.



A History of the American People

In Five Volumes

By WOODROW WILSON

Ph.D., Litt.D., LL.D

Former President of Princeton University

WOODROW WILSON

THE annals of historical literature record no more brilliant and masterful piece of writing than Woodrow Wilson's epoch-making work in five volumes—*A History of the American People*. Governor Wilson has devoted the best years of his life to the preparation of this great work. It is monumental in character and scope, and represents the genius of the greatest historical writer of the present time. It is written in that delightful, flowing style which translates historical facts into the romance of a nation.

In the matter of illustration every field of human activity has been searched, and hundreds of new portraits, prints, maps in color, plans, and pictures make the pictorial features alone tell their wonderful story of the birth and growth of what is now the United States.

The five large octavo volumes are printed on special paper and splendidly bound in dark-blue cloth with gold lettering.

We will send you the entire set of five volumes, all charges prepaid, on receipt of $5.00, and enter your name as a subscriber for both HARPER'S MAGAZINE *and* HARPER'S BAZAR for one year, at no additional cost to you. If you do not like the books when they reach you, send them back at our expense and we will return the $5.00. If you do like them send us $1.00 every month for eleven months.

P. S.—HARPER'S WEEKLY may be substituted for HARPER'S MAGAZINE.

The most perfect series of maps in color ever published, showing the territorial growth, political changes, and general development of the United States. There is a full-page portrait of every President from Washington to Roosevelt, facsimile reproductions of rare manuscripts, state papers and governmental records, together with numerous illustrations by Pyle, Remington, Penn, Chapman, Christy, and many others.

HARPER & BROTHERS
Franklin Square
New York

Gentlemen: Please send me, all charges prepaid, a HISTORY OF THE AMERICAN PEOPLE, Five Volumes, Cloth Binding, subject to ten days' approval, and also enter my subscription to HARPER'S ..... For one year, for which I enclose $5.00 and agree to send you $1.00 a month until the total price, $15.00, is paid. If the books are not what I wish, I will return them at your expense.

SCRIBNER'S MAGAZINE

· MCMXII ·

The New Serial, **THE TURNSTILE** by **A. E. W. MASON**, author of "The Four Feathers," "The Broken Road," etc., began in the October number

Robert Grant's **CONVICTIONS OF A GRANDFATHER** The changed social, political, and living conditions are dwelt upon, the question of the accumulation and uses of great fortunes, the increased cost of living, divorce, woman suffrage—almost everything of vital and familiar interest

PRICE COLLIER, whose "England and the English from an American Point of View" was a real literary sensation, will later in the year begin a series of papers along similar lines upon **GERMANY AND THE GERMANS**

The **Traces and Influences of France in the Settlement of America**, by **PRESIDENT FINLEY**. The romantic and wonderful story of the settlement and growth in civilization and power of the great Middle West, the marvellous changes that have followed in the footsteps of the old French explorers—La Salle, Marquette, Joliet, and others

SENATOR HENRY CABOT LODGE will be represented by a group of articles giving his **REMINISCENCES OF EARLY DAYS**

THE WITCHING HILL STORIES by **E. W. HORNUNG**, creator of the incomparable Raffles, past master of the short story of mystery and adventure

A most remarkable and fascinating series of experiences in a London suburb

Early in 1912 will begin **THE HEART OF THE HILLS**, a new novel by **JOHN FOX, Jr.**

Have You Seen the
Beautiful Christmas Scribner?

If you have not already sent your subscription, send it now and begin with October to secure the first chapters of Mr. Mason's story.
A PROSPECTUS for 1912 will be sent free upon application.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Our Trade With South America

AMONG the subjects of national importance which should command the attention of every enlightened citizen of the United States is that of the trade of South America and our own particular relation thereto. We commend for careful perusal the bulletin of the Pan-American Union for October, which deals with the trade of Latin America for the year 1910. The growth of the commerce of the twenty republics dealt with since 1897 is shown by the fact that whereas in that year the total commerce was $910,422,500, in 1910 it had increased to $2,848,744,000, a gain of over 150 per cent, which is about equally divided between imports and exports. These figures reveal the important and unsuspected fact that in the matter of commercial expansion Latin America has forged ahead more rapidly than the United States, the growth in foreign trade during the period referred to being $1,339,000,000 for the Latin American republics, and $1,581,000,000 for the United States.

During 1910, 55.2 per cent of the imports into the republics of North America came from the United States and to the South American republics we sent 13.64 per cent of their total imports. Taking the whole group of the Latin American republics, both in North and South America, we find that the United Kingdom leads with 26.03 per cent of the total imports, followed by the United States with 23.31 per cent. The third place is held by Germany, with 13.4 per cent, followed by France, with 8.21 per cent. The United States lead in the matter of exports received from Latin America, with 34.51 per cent, the United Kingdom, with 20.99 per cent, being second, Germany, with 11.47 per cent, third, followed by France, which takes 8.29 per cent of the exports. Seventy-five per cent of the shipments from the republics in North America come to this country, but we receive only 20.8 per cent of the shipments from the southern republics.

We are free to confess that the results shown in this bulletin are more favorable, as regards the position of the United States in the Latin American trade than we had supposed them to be. At the same time, in view of the great geographical advantage enjoyed by this country, as compared with our commercial rivals in Europe, our trade with the southern republics is far below what it should be. A better system of banking, one more adapted to conditions in South America, the exercise of greater care in selecting the representatives of our commercial houses who go down and get into personal touch with the Latin American business men, a more intelligent study of the character, disposition, tastes, manner of doing business, and particular ways and wants of the people down there—all this coupled with the creation of a merchant marine specially constructed for the South American trade, would do wonders in the extension of our Latin American commerce.

Personality and manners count for a very great deal with the Spanish American. There is probably no section of the earth where "bluff," "push," and general "get-there" methods count for so little, except as destructive agencies. The German, always analytical and scientific in his methods, thoroughly understands this fact; and the great commercial houses in Germany select their representatives with a special eye for their fitness for meeting and adjusting themselves to the idiosyncrasies of the Latin American customer. Instead of trying to make the people buy what he makes, the German tries to make what the people buy—a very simple, but a very radical and far-reaching distinction. More than that, he is careful to pack the goods and deliver them in just that very way which will render them acceptable to the customer and fit in most comfortably with his established habits and the general local conditions.

The Quebec Bridge Competition

ALMOST important contribution to the literature of bridge engineering is an article by Gustav Lindenthal, in our contemporary, *Engineering News*, on the Quebec bridge competition, which not only throws a flood of light upon the inside history of this great undertaking, but also affords a mass of instructive technical information for those who are interested in the construction of long-span bridges.

The Quebec bridge owes its celebrity mainly to the fact that it contains a longer single span than any bridge as yet constructed, its nearest competitors being the Brooklyn suspension bridge, with a main span of 1,595 feet, the Williamsburg suspension bridge, which measures 1,600 feet between towers, and the Forth bridge in Scotland, a cantilever structure, with two main spans, each measuring 1,710 feet in the clear. The cantilever structure which is to be built near Quebec will be 1,800 feet in the clear between centers of main piers.

In 1889 the Quebec Bridge Company invited tenders for a structure to carry a two-track railroad with a wagon road and trolley line on each side. Out of six competitors, the Phoenix Bridge Company was awarded the contract for the construction of a cantilever bridge prepared by its own staff of engineers, the award being made on the ground, among others, that this company's plan was the lowest in price. The construction was commenced, and when one-half of the bridge had been erected, the structure collapsed under its own weight, with the loss of eighty lives and four million dollars in property destroyed. "The primary cause of both disasters," says Mr. Lindenthal in the article referred to, "was the same: bad engineering; but in connection with the Quebec bridge was a contributory circumstance, of which it is difficult for engineers to speak without a feeling of humiliation, and that is the beggarly compensation for engineering services on a work of unprecedented magnitude, and the willingness of an engineer of high reputation and unimpeachable integrity to assume very important and laborious duties for a fee for which they could not possibly and seriously be met."

In this connection we wish to emphasize the fact that in all great engineering works of this character, the very last direction in which economy should be practiced is in that of the employment of the highest type of professional men, both for the design and oversight of the work. When such men are engaged, the remuneration should be on a scale which will justify them in allotting that measure of their own time and of the time of their office and field force, to the work, which the importance of the job demands. We need go no further back than the recent failure of the Austin dam for another object lesson in the folly of practicing overzealous economy in the matter of professional engineering services.

The bridge fell because one of the main compression members in the bottom chord of the shore or anchor span, which had been designed to stand a pressure per square inch of about 80,000 pounds before beginning to give way, failed suddenly and without warning under about one-half that load, or to be exact, under 16,800 pounds per square inch pressure. Mr. Lindenthal scouts the theory advanced in some quarters that the blame is to be ascribed to lack of scientific knowledge of compression members, which it was alleged could be derived only from full-size tests of large columns. He rather lays it to the fact that no studies of any kind were made for the unprecedentedly large compression members of the Quebec bridge until after their failure. Says he, "The leading consideration for the choice of their cross-sections seems to have been the desire of the contractor for cheap manufacture, which was not balked by the engineer. The chord members consisted each of four slabs or ribs composed of a number of thin, stitch-riveted plates, with contact surfaces painted or rather greased, insufficiently stiffened with flange angles and flimsy lattice angles. They were of a form so obviously defective that they should have been condemned at first sight. They were a pernicious example of commercial engineering, which may be defined for this case as the subordination of design to the cheapest method of manufacture, under the pretense of fulfilling specifications."

The fall of the bridge was investigated by a Royal Commission of three Canadian engineers, who made an exhaustive and able report. Unfortunately the Canadian Government dispensed with the aid of that commission, whose report formed the basis of favorable comment at the time in the columns of the SCIENTIFIC AMERICAN, and appointed a new board, which, after much labor and time brought forth an official design, which, according to Mr. Lindenthal, cost the Canadian Government about five hundred thousand dollars and two and a half years' time of the Board. Bids were invited on this design, and bridge companies were invited to submit designs of their own; but they were expected to prepare these in four months' time and without any compensation whatsoever. Ultimately, out of the many and costly competitions, which included about twenty-four tenders and eight or nine competitive plans, and tenders varying from eleven million to sixteen million dollars, an independent design, drawn up by a Canadian company "in contravention of the official specifications," providing for limited traffic capacity and costing only nine million dollars, was accepted by the Canadian Government.

Had the design for this bridge been thrown open for world-wide and unrestricted competition by the leading bridge engineers of the world, the Canadian Government would undoubtedly have secured a better bridge, and certainly would have saved an enormous sum of money. In the latter half of his article, Mr. Lindenthal, himself probably the leading authority on long-span bridges, will show that the Canadian government ultimately will have spent nearly eighteen million dollars by the time the St. Lawrence River bridge is completed, and this in spite of the fact that by a wise and judicious policy it could have secured a bridge of greater capacity with a large margin of strength, for a sum of less than ten million dollars.

Attempts to Produce Experimental Pellagra

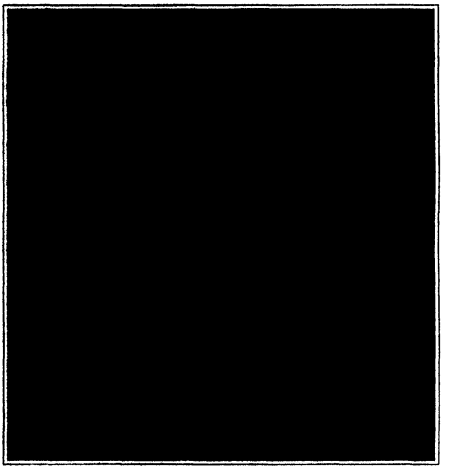
SO far the study of the horrible disease known as "Pellagra" has produced nothing to point to the etiology of the disturbances it sets up. The Italian expert, Dr. Sambon, believes that it is an infectious disease, and that it is transmitted by the "buffalo gnat" (*Simulium reptans*); Dr. Lavinder, the specialist of the United States Public Health and Marine Hospital Service, thinks that the disease is a metabolic or food disease. But until the past year no one had tried to test the various theories by means of inoculations in one of the higher animals.

If Sambon's theory is correct, an infection should be possible by means of the blood of a patient, since the organism that causes the disease must at some stage or other be present in the blood. To test this supposition, Dr. John F. Anderson, director of Hygienic Laboratory, and Past Assistant Surgeon Joseph Goldberger obtained some rhesus monkeys (*Maccacus rhesus*) and inoculated them with defibrinated blood and spinal fluid from typical cases of Pellagra. Two of the monkeys showed slight discolorations of the skin on the face; these varied in intensity and disappeared after a short time, and they were different in the two monkeys. There was no fever or any other indication of disturbance after nine months.

Dr. C. H. Lavinder, although he does not believe the disease to be due to infection, also attempted to induce the disease in a number of rhesus monkeys. In three monkeys he made intraperitoneal injections of blood from a patient, in three injections of spinal fluid, and in three injections of spinal emulsions. The emulsion was also used to inoculate culture tubes, with negative results. After six months, none of the monkeys showed any symptoms.

Drs. Anderson and Goldberg suggest that the negative results may be explained in one of three ways:

1. The monkeys may not be susceptible to the disease.



2. The technic may have been defective.

3. The infective substance or agent may not have been in the blood or in the spinal fluid at the time it was drawn.

These explanations all assume that the disease is infectious. But even on that assumption there is still another explanation possible. If the disease is caused by an animal parasite and is transmitted by the *Simulium*, there is the possibility that the organism undergoes developmental changes in the secondary host, without which it is incapable of producing the disease again.

Hudson Maxim

A Noted Inventor of High Explosives

HUDSON MAXIM

Best known for his work in high explosives and their application to modern ordnance.

ALTHOUGH the subject of the present sketch has been a close worker in many fields of activity, he is known in connection with his work in the manufacture of high explosives and their application to modern ordnance.

Hudson Maxim was the fourth son of a family of eight children, six boys and two girls. He was born October 3rd, 1853, at Orneville, Piscataquis County, Maine. His parents, Isaac and Harriet Boston (Stevens) Maxim, were of sturdy stock of English and Scotch descent.

In early years he formulated the hypothesis of the compound nature of the so-called atoms, which has only recently been generally accepted as a proven theory through experiments on radiant matter. His theory, as first published in brief in the SCIENTIFIC AMERICAN Supplement, No. 697, of May 11th, 1889, is that all matter is composed of the ultimate, and that the difference in the various forms of matter and manifestations of force is due to the difference in the relative positions of the ultimate atoms.

From 1883 to 1888, Mr Maxim was engaged in the subscription book publishing business at Pittsfield, Mass., and during this period he wrote and published a book on "Penmanship and Drawing" of which nearly half a million copies were sold by subscription. In 1888, he left the publishing business for the more fascinating occupation of inventing and experimenting with ordnance and explosives.

In 1890, he erected a dynamite and smokeless powder mill at Maxim, New Jersey, where he developed and manufactured the first smokeless powder to be adopted by the United States Government. The E. I. duPont de Nemours Powder Company, of Wilmington, Delaware, purchased his inventions and patents, employing him as consulting engineer and expert in experimental work and exhaustive experiments by the United States army at Sandy Hook. Mr. Maxim sold this Government in 1891 the secret of his high explosive Maximite. It was the first high explosive to be successfully employed as a bursting charge for armor-piercing projectiles.

Among the others of his successful inventions is a detonating fuse for high explosive projectiles, which has proven itself superior to all rival fuses, and has been recently adopted by this Government. A later invention is stabillite, a new smokeless gunpowder, which in addition to other desirable qualities, has the great advantage that it may be used as soon as produced. This, in view of the fact that ordinary nitro-cellulose smokeless powder requires several months to dry, renders stabillite of the greatest importance in the event of war. For the largest guns, more than a year is often required to dry out the solvent. Stabillite does away with all this difficulty.

Simultaneously with the invention of stabillite, Mr. Maxim produced a new self-combustive compound, which he named motorite, intended to be employed instead of compressed air for driving torpedoes of the Whitehead type. The motorite is made in bars about five feet long and seven inches in diameter. These bars are then coated on the outside and forced and welded into steel tubes. The bar is ignited at one end to which the combustion is confined until the bar is entirely consumed. Water is forced into the combustion chamber and is instantly converted into steam by the flame blast, the products of combustion and the steam mixing to produce a motive fluid which is employed to drive a turbine or other engine.

There is probably none of his inventions upon which Hudson Maxim has expended more time and effort than upon this. In addition to driving torpedoes it is also applicable for driving small torpedo-boats during the run of attack, and Mr. Maxim has designed a new type of torpedo boat, which itself forms a veritable torpedo, driven by motorite during the run of attack through the gun-fire of a warship. The boat will carry a load of high explosive in the warhead, which will be discharged against the hull of the war vessel attacked.

The process of making calcium carbide continuously by the electrical resistance of a molten carbide conductor, removing the carbide as fast as formed, and simultaneously supplying fresh material to the heating fluid, now in general use in this country, was invented by Mr. Maxim, the invention being sold to the Union Carbide Sales Company in 1906. During experiments in the manufacture of calcium carbide, he invented a process for the manufacture of microscopic diamonds by electro-deposition.

Another late invention of his is a game of skill—an improvement on chess, it is called the War Game, the movements of the pieces simulating field operations of troops in battle.

He is the author of "The Science of Poetry and the Philosophy of Language," published by Funk and Wagnalls, 1910. The work embraces an exhaustive treatise on the nature and use of sounds in language, and contains many important scientific discoveries in the constitution and dynamics of human speech.

From the foregoing one can easily appreciate what a hard worker and tireless thinker this man must be, and yet, aside from inventive labors, he has won acknowledgment as writer, critic, philosopher and sociologist. He is an effective public speaker, and is also a frequent contributor to the leading periodicals on a wide range of subjects.

He is a member of the following societies: The Aeronautical Society of New York (of which he is past president); The Military Service Institution, Society of Chemical Industry, Chemists' Club, Navy League, Fellow of the American Association for the Advancement of Science, Director of the New England Society, 2nd Vice-President of the Aero Club of New York, President of the Hopatcong Rifle Club.

Mr Maxim has had a great many narrow escapes in his long experience as an inventor and manufacturer of explosive compounds. In the manufacture of explosives, even after the work has become thoroughly systematised and the duties of the workmen become routine, there is an inseparable element of considerable danger; but in pioneer inventive work and experimentation with explosive materials, the risk of life and limb is very much greater for the reason that the experimenter is obliged to deal with unfamiliar compounds and unfamiliar reactions under unfamiliar circumstances.

The pathway of the inventor of explosive materials is like that of the vedettes of an army passing over a road planted with the torpedoes of the enemy. One becomes accustomed to the danger of explosives, Mr Maxim says, just as a veteran soldier gets used to the dangers of battle; but it does not lessen the risk.

One day, seventeen years ago, at his powder works in New Jersey, Mr Maxim was experimenting with a new fulminate compound, one of the most dangerous and deadly explosives known to science, when, owing to a little oversight, his left hand was blown off to the wrist.

At another time, at the same place, when one of his assistants was weighing out some of this dangerous material in the laboratory, an arm supporting the scoop of the scales gave way and a weight fell striking within an inch of a quantity of fulminate which was piled on a piece of glass. Had the weight struck the glass, there would have been an explosion, and as there were ten pounds of fulminate in a jar standing on a bench, the explosion would certainly have had fatal results.

At another time, requiring some dry guncotton for an experiment, and not finding a suitable vessel to put it in, he was delayed a few minutes until one should be cleaned. During those few minutes, the guncotton house where he was going for the material blew up. At another time Mr Maxim was conducting some experiments in throwing aerial torpedoes from a 4-inch cannon. These projectiles, charged with a high explosive, were fired into a sand bank one hundred yards distant. The line of fire being parallel with a line of railroad about one thousand feet away, no danger to the railroad was suspected. Several torpedoes had already been discharged and the gun was being reloaded when the whistle of a passing train was heard. The gun was fired, but the aerial torpedo, instead of striking into the bank and exploding, as the previous ones had done, glanced from the bank, mounted high in the air, and passed clear over the train into the swamp beyond, where it exploded with terrific force.

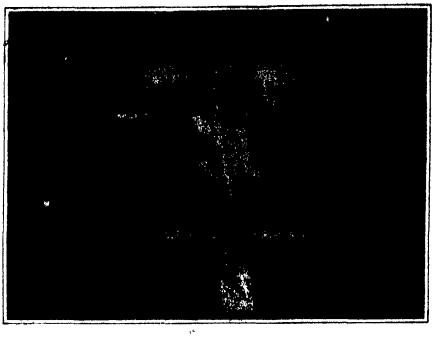
Once when he was conducting some experiments with motorite, the combustion chamber exploded like a bombshell, blowing the windows of the workshop into the street, while the walls were pierced with fragments in all directions. Mr Maxim and his assistant, though both standing in the room at the time, escaped without a scratch.

A smoker is often unintentionally the cause of many a conflagration, the exploder of fire damp in mines, and the cause of the blowing up of powder mills. No smoker and no one carrying matches is ever knowingly admitted into any powder mill or dynamite factory.

One occasion when Mr Maxim confesses to have been thoroughly scared was when an intimate personal friend, a habitual smoker, escaping the vigilance of guards and assistants, entered one of the buildings at Mr Maxim's experimental works on Lake Hopatcong, with a lighted and partially consumed cigar in his mouth, having an inch of hot ashes and cinders on the end of it ready to drop off at the least jar. When Mr Maxim caught sight of him he was standing over a large box containing fifty pounds of dry guncotton, examining the material with his hand, and upon the same bench where the guncotton rested were two other boxes filled with smokeless gunpowder, one hundred pounds in each. Mr Maxim went up to the smoker, threw a cover over the box, and quietly asked him please to stand back a little. Then he told him what he had done, and the offender was so scared that he nearly fell to the floor.

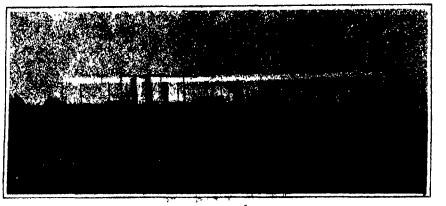
Technical Experts at German Consulates

IT is reported that the German government is about to create a new class of consular officers, viz., technical experts, who will be attached to important consulates and whose duty will be to follow the progress of industrial development in the country to which they are assigned, and to report on all novelties of a technical character. These officials will supplement the commercial experts already attached to many German consulates, who, though they are of great value in furthering the foreign commerce of the fatherland, lack the professional training necessary for answering the many technical questions addressed to the consulates by German manufacturers, engineers, etc. pertaining to the progress of applied science in the several foreign countries.



The Hydro-aeroplane

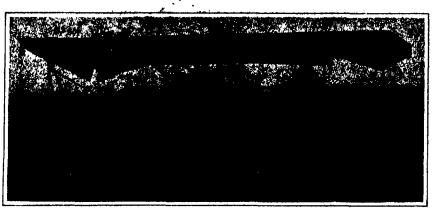
Some of the Latest Biplanes Which Have Been Fitted with Floats in Order to Make Safe Alighting From the Water Possible



THE first experimenter to succeed in making an aeroplane rise from the surface of the water was the French inventor, M. Fabre, who accomplished this feat with a monoplane of his own invention the last of March, 1910. About a year later Glenn Curtiss, at San Diego, fitted a float to his biplane and made it rise from the water and alight thereon with complete success during the course of his experiments. He flew out to the cruiser "Pennsylvania" anchored off the harbor and was lifted aboard with his machine. After paying a short visit to the ship, the aeroplane was lowered once more and Curtiss flew back to his starting point within the harbor. During the past summer the hydro-aeroplane has been experimented with by officers of the navy and two Curtiss hydro-aeroplanes have been purchased. These machines have found favor on account of their shift control, which consists of a movable wheel in front of the two aviators and mounted upon a vertical arm pivoted at its lower end so that it can be swung in front of either man. By this means it is extremely easy to shift the control wheel of the machine from one to the other pilot whenever it is desired to do so. In their long flight from Annapolis to Hampton Roads recently, Lieuts. Ellyson and Towers found this control of great benefit, as they were able to take turns in running the machine. Quite recently Mr. Curtiss has received a large order for hydro-aeroplanes for the Russian navy, and he has sent one of his aviators to Russia to demonstrate these machines, while Capt. W. I. Chambers of our own navy believes that before long each battleship will have to carry one or more hydro-aeroplanes.

One of our illustrations shows Witmer skimming the surface of the waves in the Hudson River in one of the latest Curtiss machines. This biplane is mounted on a single float, the bottom of which is rounded upward at the front, while the top is rounded downward at the rear end. This float is made of wood and is 14 feet long by 2 feet wide by a foot in depth. It will sustain a weight of some 1,400 pounds without being submerged. The front horizontal rudder is mounted above the bow of the float, where it not only serves its purpose of steering the machine in a vertical plane, but also keeps the spray from striking the aviator. At each end of the lower plane there is an inclined air cylinder which acts as a buffer and buoys up the end in case the machine tips when skimming the surface of the water. Recently Hugh Robinson made a flight in one of these machines down the Mississippi River from Minneapolis, Minn., to St. Louis, Mo., for the purpose of demonstrating its use as a mail carrier. Some five thousand pieces of mail were carried, and mail pouches were taken on and put off at the various towns on the way.

Another of our illustrations shows the "Pelican" of Capt. Hugh L. Willoughby. Instead of a single float, Capt. Willoughby has built two long, narrow floats with upcurved bows, which match the skids on his biplane. These floats are carefully constructed and are sheathed with brass, making them watertight. Their combined weight is but 103 pounds, or some 20 pounds less than that of the single Curtiss float. They will lift 1,200 pounds without submergence. The "Pelican" was fitted with only a 30-horsepower, 4-cylinder, Curtiss motor, which was not quite sufficient to raise it from the surface of the water. Now that he has transferred his machine to Sewell's Point, Va., he expects to fit a more powerful motor, and make flights above some of the streams in that [illegible]. This new hydro-aeroplane is fitted [illegible] rear horizontal rudder [illegible] in unison, the front one [illegible] which the rear one points [illegible] This is a system which [illegible] some time by Farman, [illegible] the Wrights, but Capt. W[illegible] cured patents upon it, [illegible] States and France. Th[illegible] rudders is practically [illegible] they have vertical trian[illegible] and below. Triangular [illegible] fitted at the rear ends [illegible] The inventor also has [illegible] form of throttle control whose action is just the reverse of the usual arrangement, in that when the pedal is pushed the throttle is closed and the engine slows down, while a full movement of the pedal short-circuits the magneto as well.

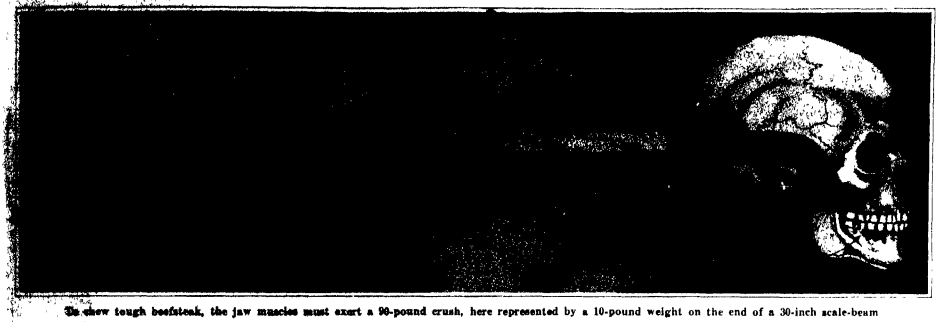


View looking down upon a Voisin "Canard" from in front.

Copyright, Boston Photo News Company.

Rear view of Burgess-Wright headless hydro-aeroplane skimming the surface at full speed.

Capt. Willoughby's hydro-aeroplane "Pelican" resting on its upcurved floats.



The single-float Curtiss hydro-aeroplane gathering speed in rough water.

THE HYDRO-AEROPLANE

Both the Wright and the Burgess-Wright companies brought out a hydro-aeroplane. A Burgess-Wright biplane, viewed from the rear, is shown skimming the surface of the water in one of our illustrations. Like the "Pelican," it is provided with double floats, but the skids instead of resting upon these floats, are rigidly attached to the aeroplane by means of suitable uprights. These floats are single-step, cedar wood hydroplanes 14 feet long by 2 feet wide, and having a 4-inch step placed about [illegible] the middle.

A fourth illustration shows, viewed from the front and above, the Voisin hydro-aeroplane known as the "Canard" (duck) skimming the surface of the water before soaring in flight. This biplane, which has a long body projecting forward in front, is mounted upon four floats, two of which are [illegible] visible beneath the lower [illegible] about half-way between the body and the ends. The third float is also visible beneath the body about half-way out from the front of the main planes. The horizontal and vertical rudders can be seen at the front end of the body, while the two men in the body are peering over the side as the machine travels forward. The propeller is also visible across the rear end of the body. This machine, mounted on wheels, was described some time ago in the SCIENTIFIC AMERICAN. During the past summer it was fitted with Fabre floats, and has made many successful flights from the surface of the Seine, near Paris. M. Fabre's original monoplane was built on the lines of the "Canard," and was fitted with small floats, placed in practically the same positions as they occupy in this machine. M. Fabre experimented for a long while before he was able to obtain floats that would stand the shocks of the waves and remain watertight. He finally found that several layers of veneer was the most suitable substance for this purpose.

Recently the Aeronautical Society has obtained grounds at Bergen Beach, near New York, for the purpose of making it possible for its members to experiment on the water next summer. As the members are alive to the possibilities of the hydro-aeroplane, without doubt there will be a number of these machines developed next year. The advantage of the hydro-aeroplane is that it can follow water courses that cannot be traversed by motor boats, and can travel much faster than any of these craft. In case of accident or a forced landing, there is always a good place upon which to alight. There are thousands of miles of rivers and canals in the United States above which amateur aviators can fly in safety, and without doubt another year will see a great development in the popularity of the new sport of hydro-aeroplaning.

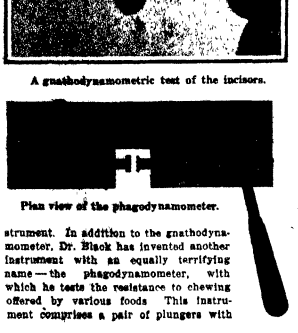
To chew tough beefsteak, the jaw muscles must exert a 90-pound crush, here represented by a 10-pound weight on the end of a 30-inch scale-beam

The Power of the Human Jaw

The Work We Do In Biting and Chewing

A TEN-POUND bite requires a forty-pound contracting of the human jaw muscles. That is because the jaws are built on the principle of a pair of tongs. The power is applied near the joint, while the work is performed at the opposite extremity of the jaw levers. Had a mechanical engineer designed the human frame, he would no doubt have built the jaws after the fashion of a nut cracker, with the muscles placed at the ends of the jaw levers, and the teeth between these ends and the joint or fulcrum, so that a powerful bite could be obtained with a very small expenditure of muscular effort. However, in the physiology of men and all other animal life, for that matter, mechanical advantage weighs for little in the presence of other broader considerations. This is why nearly all the principal muscles of the body must be far more powerful than would be necessary were they to act directly upon the work. When chewing we have an almost direct application of the power of the muscles, as they nearly overlie the third molars. There is a vast difference between chewing and biting.

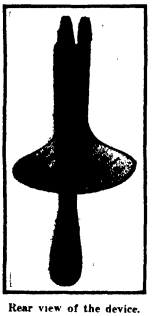
The gnathodynamometer.



In order to determine the average strength of the jaws, Dr. G. E. Black, president of the Chicago Dental University, some time ago devised an instrument of very simple design but with a name that would put the average jaw to a severe test—the gnathodynamometer. With this instrument he made gnathodynamometric tests of the jaws of a thousand persons. They were selected at random, and probably represent a good average of civilized people. He found that the limit of the bite was not determined by the muscles, but by the teeth themselves. In nearly every case, the patient would cease his efforts, owing to the fact that his teeth hurt. This would depend largely upon the condition of the peridental membranes, and upon the habits of the patient in accustoming his teeth more or less to chewing hard foods. The average of the thousand persons showed 171 pounds for the molar teeth and much less for bicuspids and incisors. Out of the one thousand persons, seventeen developed a force equal to the full registry of the instrument, which was 375 pounds.

In a recent publication, Dr. Black has tabulated the records of about fifty persons who were tested with the gnathodynamometer. The list includes men and women of all classes, from a blacksmith to a Chinese missionary, and from a servant girl to a music teacher. It is natural to picture a butcher as a man with a well-developed and powerful jaw, but among the patients in the fifty the butcher showed a power of only 165 pounds with his molars, from which we may infer that he is accustomed to selecting tender meats for use on his own table. The man with the highest record was a printer who registered 270 pounds, (but any compositor will admit that printers' pie is tough) while the second honors went to a dentist with 240 pounds. Among the women the highest record reached was 160 pounds, while the lowest was 45. Strangely enough, the schoolgirl who made the latter record was able to register 70 pounds with her incisors, which might indicate that she had accustomed her dental membranes of the front teeth to harder work by biting a pencil, or something of the sort. At any rate she was one of those unfortunates who "bite off more than they can chew." In this list of records, males showed an average of 160 pounds with the molars and 88 with incisors, and females 108 pounds with the molars and 67 with incisors.

The instrument with which these records were made comprises a pair of steel arms, which are normally spread apart by spring tension. Each arm is equipped with a rubber pad, on which the biting is done. When the patient bites the pads, the levers are forced toward each other, and cause an index needle to travel over a graduated arc which shows the force of the bite in pounds. One of the difficulties that had to be contended with was that the full power of the muscles cannot be exerted until the jaws are nearly closed. This made it necessary to reduce the biting pads to a minimum compatible with safety. In selecting patients whose jaw muscles were to be tested it was imperative that the teeth be examined for any indications of decay which would weaken them to such an extent as to cause injury when biting on the in



A gnathodynamometric test of the incisors.

Plan view of the phagodynamometer.

strument. In addition to the gnathodynamometer, Dr. Black has invented another instrument with an equally terrifying name—the phagodynamometer, with which he tests the resistance to chewing offered by various foods. This instrument comprises a pair of plungers with toothed surfaces at their adjacent ends. By means of a lever one of the plungers is forced against the other. The latter acts upon a spring, connected with an index needle arranged to sweep over a dial. The pressure of one plunger upon the other plunger may then be read on this dial. With this instrument, some important studies have been made of the force required in the mastication of food. These are shown graphically at the top of this page. In place of muscles the jaw is represented as being provided with a scale beam and a 10-pound sliding weight on the beam. If the weight be moved to the point marked 50, a fifty-pound crushing force will be exerted at the second molars.

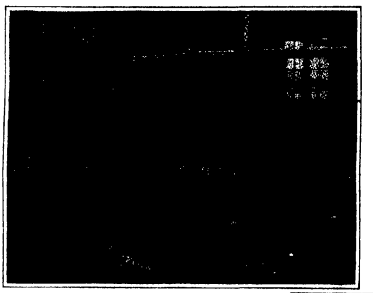
Rear view of the device.

The tenderest meat was found to be boiled tongue, the central part of which offered a resistance of from three to five pounds. Boiled tongue, when cold, offered a resistance of from fifteen to twenty pounds. In order to crush pork chops loin, a force of from twenty to twenty-five pounds was necessary. Mutton chops required from thirty to forty pounds, beef, round from forty to fifty, and beefsteak, well done but rather tough, from sixty to eighty pounds. An experienced butcher selected some very tough meats, from the neck of an old animal, which stood up against a force of from seventy to ninety pounds before the crush occurred. These tests were made a number of years ago, before storage meat was used to the extent it is now. The figures should be reduced about one-third for meat made tender by storage. With these data the mathematically inclined may proceed to figure out the horse-power developed at the boarding-house table.

A surprising fact brought out by the use of the phagodynamometer is that the hardness of food does not determine its danger to the teeth. For instance, candies that are quite hard offer much less danger to the teeth than gum drops, which ordinarily are mashed out of shape at from twenty to thirty pounds. If part of the gum drop became wedged between the cusps of the teeth, it was found that frequently it could not be completely crushed with a pressure of less than 350 pounds. Sticks of licorice proved particularly dangerous in this way. But the most remarkable discovery was that even bread might cause the breaking of a cusp. To quote Dr. Black, "With my personal observation, more teeth that seem sufficiently strong have been broken with bread crusts, and not very hard crusts either, than with any other one thing. I used sometimes to feel that persons relating these accidents were not quite honest in their statements, but when I tried the bread and found that it would wedge in between the cusps of the teeth, and not be crushed out with a force of 350 pounds, I changed my mind."

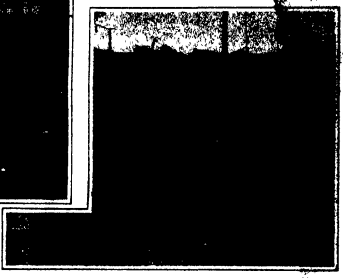
The Manufacture of Yeast

An Important Fermentation Industry

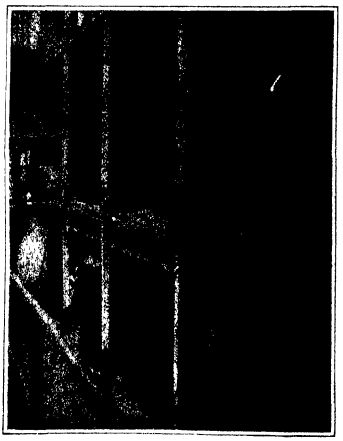


THE ferment used for raising the dough in making bread is a microscopic fungus, so-called yeast, or, as it is called by the biologist, saccharomyces cerevisiæ This organism grows in saccharine liquids, reproducing by budding Its cultivation constitutes quite an important industry, some of the essential steps of which, as carried out in France, are illustrated in the accompanying views The raw materials in this industry are barley, rye, and Indian corn The first operation consists in cleaning this material in special engines provided with metal brushes, sorters, and separators After the dust and other adventitious material has been thus eliminated, a certain portion of the grain is passed through a mill and is ground to flour The remainder of the barley is taken to another part of the plant, located in the basement, where the operation of malting and germinating is carried on In the course of this process a certain ferment known as diastase, is developed in the grain, which has the property of transforming starch into fermentable sugars Throughout the malting operation it is necessary to observe careful precautions in regulating the temperature and humidity, as these factors exercise an important influence upon the proper course of the process The temperature commonly employed is from 12 to 14 deg Cent The ordinary method of germinating the grain requires an extensive floor area and great attention on the part of the workmen and is moreover applicable only at certain times of the year, for if the malting is carried on during the hot weather, there is apt to be a very serious development of mold. This last inconvenience has been very successfully overcome by the so-called pneumatic malting process introduced by Galland and others This consists simply in circulating through the grain a current of air whose moisture and temperature is regulated according to atmospheric conditions and to the particular phase in the process The wet barley is placed in double-walled sheet iron drums or cylinders, through which the regulated air current is passed, while the grain is slowly turned over by rotating the drum about its geometric axis, for which purpose the cylinder is mounted upon four rollers, and is provided at one extremity with a toothed wheel engaging a worm gear The cylinder rotates once in about forty minutes

The fermentation vats.



Rotary germinating drums.



The filter press.

The charging and discharging is effected through a man-hole closed with a door, while a platform gives the foreman access to the drum and enables him to observe the progress of the operation After some eight or nine days the germination is sufficiently advanced, and the diastase is fully developed It is then necessary to stop the operation, for otherwise the young plant would continue to grow, giving rise to other changes than those which are the manufacturer's object. It is time to take the barley out of the malting drum and to proceed to the next operation, which consists in drying the grain at an elevated temperature This is carried out in long rectangular rooms built of brickwork, and measuring about twenty-three by thirty-three feet in length and breadth, and about forty to fifty feet in height. In these hot rooms the barley is spread out upon sheets of metal gauze, in layers about four inches deep, and is allowed to dry gradually A short chimney at the end of the building allows the escape of the water vapor liberated in the process of drying. After the drying operation is completed the grain is next passed on to a riddle, where the rootlets formed during the germination are broken and separated. The grain is next

Science

Peculiarities of Hail-stones.—The peculiar formation of hail-stones and the probable conditions of their production have long been matters of much interest to scientists. A thorough study of them, it is believed, might throw much light on various meteorological phenomena, especially in regard to air-currents, changes of temperature and of pressure, etc., in the upper strata of the atmosphere. A comparison often made with the "ice flowers" and snow crystals or stars which Tyndall and other prominent scientists have found so fruitful a field of investigation might yield important results. Heretofore, however, the comparative rarity of their occurrence and the great rapidity with which they melt, has offered obstacles to this But Prof. Boris Weinberg, of Tomsk, Siberia, has just perfected an apparatus, as we learn from *Les Annales*, which is expected to obviate these difficulties. He will gather the hail-stones as opportunity offers and preserve them by plunging them into liquid of about the same density contained in a double-walled receptacle like a superior ice cream freezer, but "packed" with a mixture of ice and sulphate of copper As needed for study the stones can be removed, sliced in extremely thin sections and photographed by a polarizing microscope or autochromatic plates, as is done with anatomical preparations.

The Eruption of Taal Volcano, in the Philippine Islands, which took place January 30th, 1911, and caused a loss of 1,300 lives, has been the subject of a large number of important papers in the scientific journals, besides the official reports of the Philippine Bureau of Science One of the most graphic descriptions is that of Rev M Saderra Maso, which is published as a special bulletin of the Philippine Weather Bureau. This account is noteworthy for the attention devoted to the meteorological and seismological features of the eruption, and in this respect it is an important contribution to the science of vulcanology This volcano has been the seat of repeated disastrous eruptions, the greatest of which was that of 1754 All the eruptions of which a record has been preserved have had the same character as the recent one, consisting of violent explosions which hurled the volcanic products to great distances. The huge vapor column of the last explosion rose to a height of from 20,000 to 30,000 feet, and was seen 250 miles away, where it was mistaken for a distant thunderstorm One remarkable feature of the volcano is that no lava has ever issued from it in a liquid state the ejecta being blown to dust and ashes by the pressure of gases or steam. The late eruption appears to have been marked by unusually magnificent displays of volcanic lightning For three days preceding the eruption a constant succession of seismic shocks were felt over a wide area, and they caused much alarm in Manila, until the Weather Bureau located the epicenter in the region of the Taal Volcano The partial vacuum produced at the moment of the explosion and the resulting diminution of atmospheric pressure set up strong winds blowing in toward the volcano. This wind was felt as far away as Manila (39 miles) At points nearer the volcano it assumed almost hurricane violence, impeding the movements of people who were trying to flee against it, producing tremendous waves on Lake Bombon, causing sheets of iron roofing to fly about, etc. At a distance of 14 miles Father Maso saw the cogon grass lying like wheat which had been beaten down by a storm. He is of the opinion that the wind assumed a rotary motion, in accordance with the general laws of storms, so as to produce a transient tornado or whirlwind. The atmospheric waves propagated outward from the volcano were recorded on biographs to a distance of 200 miles

Engineering

Need for Navy Colliers.—The Navy Department has chartered six Scotch steamers and one American steamer to carry coal from Norfolk to San Francisco for the use of the Pacific fleet The Scotch steamers will charge $5.40 a ton; the "J M Luckenbach," the only American vessel that competed, asked $8 a ton, which bid the navy accepted

Test of a 21-inch Torpedo.—A torpedo designed for the navy, during a recent test in Sag Harbor by the Bliss-Leavitt Company, traversed more than ten thousand yards, when fired at a 32-knot speed At 27 knots it covered a range of over 8,000 yards Most of the torpedoes now carried by battleships and armored cruisers have a speed of 35 knots and a range of 5,000 yards.

Dynamite for Farming.—Experiments were recently made in New Jersey to demonstrate the efficacy of a low-freezing explosive in aerating the sub-soil and digging a hole for tree-planting The discharge breaks up the adjacent ground and renders tenacious sub soil porous and sponge-like, thereby favoring a conservation of the moisture It is claimed that a deeper root penetration becomes possible, and that the crops are not so sensitive to spells of dry, hot weather

The Twenty-second Dreadnought,—The "Centurion," launched November 18th at Devonport, is the twenty second dreadnought to be put afloat for the British navy She will have a displacement of 23,500 tons, and a speed of 21 knots The armament will consist of ten 13 5-inch guns and twenty-four 4-inch guns Her armor on waterline and turrets will be 12 inches thick She will have three torpedo tubes for the discharge of the new 21-inch torpedo whose effective range is 7,000 yards

The 1000-foot Vessel.—A dispatch from London says that the White Star Line has ordered from Harland & Wolff a liner which will exceed the "Olympic" by one hundred feet in length As this ship measures 882½ feet, it will be seen that the new vessel will be approximately one thousand feet long Although the report lacks verification, it may well be true, although the question may be asked on this side of the Atlantic "Where will she dock?" Even the White Star docks with their temporary lengthening of one hundred feet would not accommodate such a ship, whose stern would project over 80 feet into the North River

Praise for American Shipyards.—United States shipbuilders recently were paid a flattering tribute by Admiral Garcia, of the Argentine navy. The Admiral recently made a close study of European shipyards in connection with the letting of the contracts for the two battleships which are being built respectively at the Fore River yard and at those of the New York Shipbuilding Company. He stated that in many points of equipment and management, our shipyards are decidedly superior to the most renowned shipyards of Europe—a statement which will not be surprising to those who are familiar with conditions in the best of our home yards.

Expert Testimony on "Olympic" Collision.—The recent summoning by the British Government of Naval Constructor P W Taylor, U S N., as an expert witness in the Admiralty trial in connection with the collision between the "Olympic" and the cruiser "Hawke," brings to mind tests made by Mr Taylor in the model tank at Washington These experiments with four models towed at different speeds and in various positions with regard to one another, show that one vessel overtaking another is repulsed by the forward vessel until an overlap of one-third has been established Then there is a sudden change, the rear vessel being strongly drawn toward the leading vessel

Aeronautics

Fowler's Flight Eastward Across the Continent.—After being stuck in the sand 15 miles west of El Paso, Texas, for eight days with his Wright biplane, on account of a balky engine, Aviator Fowler finally flew over the town and landed within it on November 13th He expects to finish his trip *via* New Orleans and the Southern States

Flight Aircraft with Mortars. Recently the experiment was made at Sandy Hook of firing at aircraft with a 12-inch mortar, which proved that this was an effective weapon for the purpose The mortar fired a shell filled with shrapnel, and the targets were a number of small captive balloons The test proved very successful even with balloons at high altitudes Then a number of balloons were liberated but even with free balloons the average of the hits was good Experiments of this sort are soon to be conducted with aeroplanes as targets

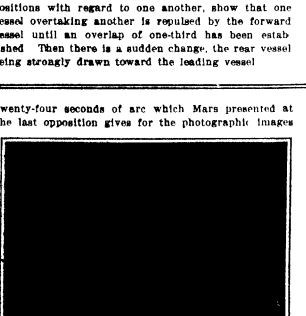
Bomb-dropping from Aeroplanes in Actual Warfare.—According to the latest report from Tripoli an Italian military aviator succeeded in dropping four bombs into the Turkish encampment on November 1st The bombs, which contained picric acid exploded and a few hours later an aerial reconnoiter showed the Turks had vacated the spot Flying over the desert is quite similar to flying over the sea, according to the experience of the Italian aviators but while at a height of 1,000 feet a fine view is obtained, if the aviator ascends 300 feet farther even, the earth is generally concealed by a blanket of fog It is therefore difficult to reconnoiter at a safe elevation The aviator who dropped the bombs also found it difficult to determine what damage had been done It is therefore suggested that a second aeroplane should follow with an observer who can keep the pilot of the first aeroplane informed as to the havoc he is creating

An American Wins French Military Aeroplane Tests.—As forecasted in the article on the French military tests, Charles T Weymann, with his Nieuport monoplane, won the 186-mile cross-country race He covered this distance in 2½ hours as against 3¼ hours required by Prevost on a Deperdussin monoplane, which also was propelled by a 100-horse-power Gnome motor Weymann's Nieuport weighed 484 kilogrammes (1,065 pounds) and carried as much again in live load and ballast Thus over a ton was driven through the air at a speed of 72½ miles an hour for a distance as great as from New York to Philadelphia and back The fact that Weymann carrying so much weight averaged nearly as much as he did with a stripped machine in the International Cup race on July 1st last, is another proof of the small head resistance of the marvelous Nieuport monoplane

Orville Wright's Flights in a Glider at Kitty Hawk.—Upon his return home from his memorable flights without a motor at Kitty Hawk N C—flights in which he remained aloft 7¾ and 9¾ minutes, respectively—Orville Wright said that these motorless flights were the most difficult he had ever undertaken, the conditions under which they were made being much more severe than those ever met with in a power-driven aeroplane Measured with a Richard anemometer the wind one day at the top of the hill had a velocity of from 17 to 25 meters per second (38 to 56 miles per hour), while 12 feet above the top of the hill the wind velocity was still greater There was a difference of 5 meters per second in simultaneous observations made at heights of 6 and 12 feet, respectively Mr Wright believes his experience at Kitty Hawk will be of great assistance in designing new machines to meet severe weather conditions

The Latest Photograph of the Planet Mars

By Mary Proctor.,



DR. PERCIVAL LOWELL, of the Lowell Observatory at Flagstaff, Aria., has been finally successful in obtaining photographs of Mars, which establish beyond a doubt the reality of the canals of Mars Heretofore, the value of the photos obtained by him in 1907 was questioned, on account of their minuteness, being compared in size to the head of an ordinary pin. Doubts were expressed as to the amount of detail which could be seen on so small a scale, and magnification, it was said, only increased the difficulty by enlarging the silver particles upon the plate, wherever its sensitive surface had been exposed to the light.

With regard to photographs of Mars obtained October 11th, 1911, with the Lowell refractor, 24 inches aperture, the images made at one minute intervals of exposure, each of three seconds, Dr. Lowell writes as follows, in a letter dated November 9th, 1911:

"The following, therefore, will interest you and the public generally—the magnification used for the photographs is now 178 diameters. This on a disk of twenty-four seconds of arc which Mars presented at the last opposition gives for the photographic images a diameter 2.3 times that of the Moon to the naked eye, and a superficies of over five times that presented by our satellite to naked eye vision—rather a surprising revelation this as to the size of our photographs

"Believe me, yours very truly,

(Signed) PERCIVAL LOWELL"

Photographs of Mars, taken at the Lowell Observatory by Mr. E. C. Slipher on October 11th, 1911.

The diameter of Mars at the last opposition was twenty-four seconds of arc less than now Superficies in the above letter, means surface of original photographic images which then covered an area over five times that presented by the full Moon to the naked eye, the telescope magnifying one hundred and seventy-eight diameters While the canals are plainly visible on the photographic plate, they will not bear printing processes On examining the enlarged image through a screen by a stereopticon an immense amount of elaborate detail appeared, several of the canals being plainly in evidence As these photographs were taken a month or so before Mars had reached its nearest to our planet, we may look forward with interest to those which will be obtained on the date of nearest approach

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them

Family Likeness in Handwriting

SOME of our readers may have amused themselves with the hobby of reading character from a person's handwriting. The indications thus obtained may perhaps also be applied for serious purposes. If a person's writing discloses his character, and if individuals of the same family resemble one another in their characters, we must expect to find that there will be a resemblance shown in their handwriting also. That this is indeed the case is shown very clearly in a number of examples illustrated by R. H. Chandler in *Knowledge* and reproduced here. Perhaps the most striking case of general resemblance is the handwriting of two sisters which is reproduced in Fig. 1. Note especially the formation of the word "the," which

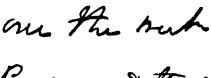


Fig. 1.—Handwriting of two sisters.

is almost identical in the two cases. Somewhat similar remarks might be applied to the cases shown in Figs. 2 and 3, while the resemblance of the characters

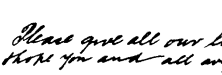

Fig. 2.—Three brothers write very similar hands.

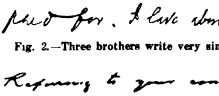

Fig. 3.—The writings of these two brothers are almost undistinguishable.

shown in Fig. 4 is less obvious but is really most striking when we examine into details. Note for example the peculiar method that both father and son follow in lifting their pen in writing the word Belvedere. Each makes an entirely separate act of writing the "e" in the middle of this word. Another feature common to both writings is that the letters increase in size toward the end of each word. This is especially marked in the first example, the father's writing

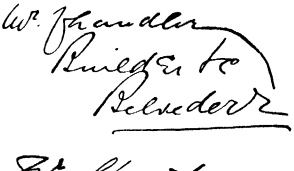

Fig. 4.—Father and son. The resemblance here is in details rather than in general form.

Motor Trucks for Mines.

MR. H. M. BEATSON, writing in *The Engineering and Mining Journal*, draws attention to the utility of automobile ore trucks at mines where ore is hauled by wagon to mill, smeltery or railroad shipping station: "There should be a demand for such trucks just as soon as wagons suitable for hauling ore are placed on the market. The automobile truck is a comparatively recent development. It is still hardly beyond the experimental stage, but it already gives promise of hauling ore at a smaller cost than such work can be done by teams.

"At some mines traction engines have been used for hauling a string of wagons. Where the roads were comparatively level and in good condition, they proved to be satisfactory, but the traction engine is too heavy in proportion to its tractive power to do the work that could be expected from the lighter gasoline-motor truck. The traction engine sinks deeply into soft ground, cannot readily run on steep grades, and is too heavy to safely cross the wooden bridges that are so frequently used to carry a road across a stream. The motor truck is free from most of these defects, but in order to pull a number of wagons in one train some special provision will have to be made to control the trailers on steep grades.

"This has been the object in view of a German manufacturing company that has recently built a road train in which the lightness of the gas-motor truck is combined with the advantages of a traction engine for pulling a number of wagons. The train consists of a generator wagon and six trailing motor wagons, each of which is capable of transporting five tons at a speed of seven to ten miles per hour. The two gasoline motors drive two electric generators. For each axle of all the wagons there is one driving motor. Steering is effected from the driver's wagon, and the provision of suitable shafting between the trailers causes them to follow the bends or curves in the road taken by the generating wagon.

"*It is said that these trains can travel readily over* rough ground, that the wheels, which are fitted with broad tires do not sink into sandy soil. The weight is better distributed and is less than that of a traction engine of equal power."

The Workman's Attitude Toward the Machine

IN a recent number of *Die Umschau*, under the heading "What the Workman Thinks of the Machine," F. Müller gives an account of impressions gathered by him regarding the place which machinery occupies in the mind and life of the workman. The method which the author has adopted to obtain his material is to approach a large number of workmen, requesting them to express their views to him by letter. He quotes passages from a number of such letters, from which a few excerpts are given below.

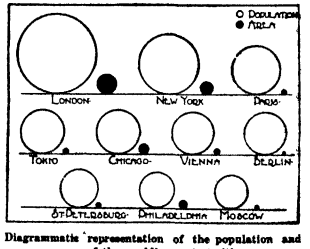
An umbrella maker writes: "For the last twenty-two years I have had my post at a special machine for making umbrella ribs. There are hundreds of members and joints working at a time. The eye finds it quite impossible to follow all the motions. The first impression which the machine made upon me was one of admiration, coupled with a certain dread. I believe man would be better off if there were not so many machines in use. My machine can hardly be said to be dangerous, unless a man commits some act of extreme negligence. In such case it is true that I have known one of my own fellow workers to have his hand crushed into a shapeless mass. I shall never forget the sight. Such accidents harden a man and seem to turn him into a machine himself."

Another writes: "If an accident has occurred in the works, it often affects a workman in such a way that he becomes extremely nervous and excitable. At every chance outcry, made perhaps in jest by some one of his fellows, he imagines that some one has been caught in the machine. The accident will torture such a man in his sleep, from which he will wake up with a start in the grip of a horrible nightmare."

A glass maker in Düsseldorf, who has been at his work for thirty-two years, makes the following thoughtful observation: "I am of the opinion that a man attending a machine cannot follow up an idealistic train of thought, but becomes deadened in his sensibilities. On the contrary, in the pursuit of some congenial manual labor, such as glass making was until recently, he has an opportunity to do this. There is a peculiar charm in watching a gang of men working at the tank furnace and singing at their work. It seems a pity that the machine should put an end to all this. In the machine room there is always a certain depression. My opinion is, living for a prolonged period with the machine means a [illegible] drying of a man's higher instincts."

Another workman remarks: "It is found that machine attendants are much more irritable and more easily given to anger than manual laborers."

This complaint of the strain upon the nerves, the ill effect upon the man's temperament, occurs almost all the letters published by the author; is too, is found the statement that the workman's is disturbed by evil dreams about accidents. says: "I believe that we should be much without the machines, and that there would quarters less cripples in our population than present conditions." This statement may, perhaps thought exaggerated, and is here quoted for what is worth. Nevertheless, it evidently represents a *mon impression among workmen, for close upon it we* find an observation by another workman, who says that "of four hundred and fifty machinists on wood-working machines in Munich, there are not ten who still possess their ten fingers."



While it appears probable that the workmen's mates may in some cases be exaggerated, through natural horror at some of the terrible accidents witnessed by them, the mere fact that this impression exists is sufficient to command our very thoughtful and sympathetic attention.

The Great Cities

SOME interesting facts relating to the population statistics of the world's great cities are cited by Prof. W. B. Bailey in the *Independent*:

There are at present ten cities in the world with a population of over 1,000,000. Of these, three are in the United States. Russia is the only other country to have more than one city of this size.

London leads with a population of over 7,000,000; but its area is over 440,000 acres. The area of Greater New York is less than half that of London. If New York city could annex enough of its suburbs to make its area equal to that of London, it would at present have a population of over 6,000,000. Even without annexing any more territory, New York may, within twenty years, become the greatest city in the world. If it were possible to include suburbs, as has been done by London, it might become the leader within ten years. The area of Registration London, not including the outer ring, is 74,839 acres. On this territory is found a population of nearly 5,000,000, but within the past decade the population of the old city of London has actually decreased. Business is crowding residences from the center.

Diagrammatic representation of the population and area of the world's greatest cities.

Berlin has recently annexed suburbs with a population of nearly 1,000,000. It seems likely that when figures are available it will be discovered that Berlin has displaced Paris as the third city in the world. The following are the population and area of the ten largest cities in the world at the latest date for which figures are available:

City.	Area in Acres.	Population.
London	441,600	7,252,983
New York	209,313	4,766,883
Paris	19,280	2,763,393
Tokio	27,982	2,186,079
Chicago	117,447	2,185,283
Vienna	39,686	2,085,539
Berlin	15,698	2,070,695
St. Petersburg	22,991	1,876,000
Philadelphia	81,328	1,549,008

Suggestions for the Workshop

Ingenious Expedients of Resourceful Mechanics

A Secret Lock for a Cabinet Door

By William J. Horner

THE method of locking shown in the illustrations is suitable for secret doors or panels which are not supposed to open, or it may be used on hinged cupboard or cabinet doors in addition to or in the absence of an ordinary lock. The principle is that of an inside latch or bolt operated by a knife blade, or similar thin instrument, put through a crack between the door and its framework. If a crack for this purpose is undesirable it would be easy with a little ingenuity to work the bolts by a string or wire carried to a convenient point away from the door. Although the method of operating the lock may give the idea that it is an insecure and weak fastening, it actually may be very strong indeed, for the strength of a lock

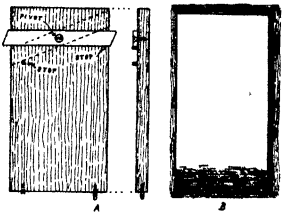

Fig. 1.—Panel with swivel cross bar.

does not depend on the size or character of the key which opens it.

Fig 1 shows a panel or cover and the opening into which it fits. A swiveling cross bar is pivoted to the inside face of the panel. When in the horizontal position the ends of the bar project and fit either behind adjoining panels or into slots, and the panel is locked in place. When the bar is swung into the position shown by the dotted lines its ends are flush with the edges of the panel. Stops are inserted as shown to permit only just the amount of swing required. The lower end of the panel has fixed pins or dowels to secure it, or the wood may be tongued or rebated. Screws with their heads filed off make good pins. Shoulders are necessary in the opening to prevent the panel from being forced inwards, and when it is locked it should be tight. If desirable nail heads

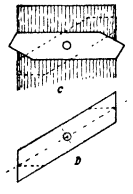

Fig. 2.—Modified form of cross bar.

Fig. 3.—Door with short fastenings.

may be driven in at each end to give it the appearance of being nailed in place.

The cross bar shown in Fig 2 is a neater shape than the simpler form in Fig 1. Its ends are cut so that the points are central instead of being at opposite edges of the bar. Besides this it will be seen in the dotted position that the portion cut from the highest part gives a horizontal edge which can be set to just clear the shoulder against which the panel beds and so the center of the bar can be slightly nearer the end of the panel. The way the bar is marked out is apparent at *D*. It may be of wood or metal.

So far the examples show bars running across the panel and securing it on both sides. Fig. 3 shows a hinged door with short fastenings at the side which opens. They are pivoted midway of their length so that they will balance. The dotted vertical pieces which cross them are guides which act both as stops and relieve the central screw from strain if an attempt is made to pry the door open.

Unless the panel is very narrow these would be necessary in Figs. 1 and 2. The stops shown in Fig 1 are suitable where little strength is required but if the panel is forced outward the bar, secured only at

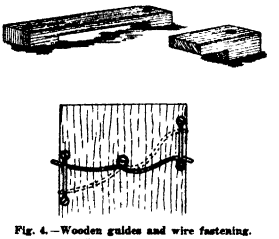

Fig. 4.—Wooden guides and wire fastening.

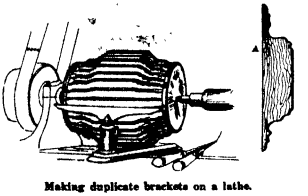


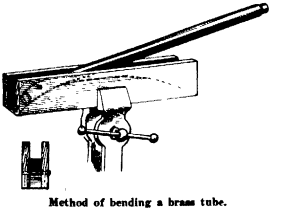
the center, may break or bend and the screw be loosened. Combined guides and stops, as shown in Fig 4, screwed to the door close to the edge, prevent this and greatly strengthen the fastening. The double-ended guide in Fig 4 stops the bar in each direction and keeps it close to the door surface. The single one is intended for use where there is not room for the longer one. It would be suitable for stopping against the lower edges of the bars in Figs 1 and 2, at the right-hand sides, where, in the dotted position, there is no room above the bar for attaching a double stop and guide.

Fig. 4 also shows a fastening on the same principle made of wire instead of wood. The wire is bent to a curve so that its ends project nearly at right angles in all positions of its travel. If it was straight and consequently at right angles in one position and sloping in the other a knife would not work it so easily. Moreover when bent its extension can be adjusted exactly as required by further bending.

Turning Duplicate Forms

By Albert F. Bishop

A WOODWORKING firm received an order for several hundred brackets which naturally would be sawed on the jig saw. The party ordering the brackets stated that they must be perfectly smooth on the sawed edges. The sawyer knew at once that if each piece was sandpapered by hand on the edges, the extra time required would greatly delay the work. His fellow workman, a wood turner, said he could make the pieces in a lathe. This is how he did it. He took a log of wood for a hub, and with a wobble saw cut longitudinal grooves in it to receive the



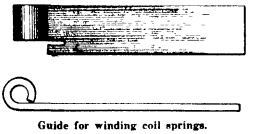
Making duplicate brackets on a lathe.

bracket pieces. These were previously cut a trifle long, leaving a little tip on each end to be clamped by the iron bands that were put on each end of the hub. The whole thing was placed in the wood lathe and turned by hand like the pattern marked *A*. The sandpapering and polishing came next, which made the forms absolutely smooth and gave them a nice finish. In doing work by this method care was taken to fit the pieces nicely so as to prevent chattering and slivering on the sides.

Bending a Brass Tube

By A. F. Clark

IN the issue of May 6th is described a process for bending brass tubing. The following is a much simpler method where a coil spring long enough and of the proper size is not available. Plug one end of the tube with a piece of wood and then stand it on end and fill it with dry sand. Tamp the sand firmly by striking the plugged end on a block of wood. When the tube is full plug the other end also with wood, then take a piece of hard wood as thick as the outside diameter of tube and saw it to the shape you wish to bend the tube; then nail two other pieces of wood,



Method of bending a brass tube.

one on either side of the form. Clamp the whole firmly in a vise as shown in the sketch. Then drive a nail through the two outer pieces near one end of the form under which insert the end of the tube, after placing a small piece of flat iron or a chisel between the nail and the tube. The two outside pieces are necessary as all tubing has a tendency to flatten while being bent. After the tube is bent the wooden plugs can be easily removed by inserting a wood screw into them and, after warming the end of the tube, using the screw as a handle to pull out.

Guide for Winding Coil Springs

THE accompanying illustration shows a small tool which will be found useful for winding coil springs in a lathe. It is made of a piece of three-sixteenth inch sheet steel, one end of which is turned over to fit the arbor on which the spring is to be wound. A slot is cut in the tool near the arbor bearing, to serve as a

Guide for winding coil springs.

guide while winding the spring. The tool is placed on the arbor and the latter is centered in the lathe. One end of the wire is fastened in a hole drilled in the arbor and then, by passing the wire through the slot, it will be guided as the arbor is turned to make a uniform spring.

Grinding Copper.—When it is desired to grind copper on a carborundum wheel the copper invariably clogs. By rubbing on tallow this is prevented and apparently the tallow does not interfere with the cutting of the wheel.—B. F.

Knife Made from a Hacksaw Blade

By H. M. Nichols

THE steel used in hacksaw blades is well adapted for making knives, as it can be ground to a good keen edge that stands up well under usage.

The knife shown in the illustration was made from a hack saw blade ¾ inch wide and about 1/16 inch thick. The blade part was ground off on an angle, as shown, and the handle was formed by bending a piece of sheet zinc in the form of a U over the back of the blade. Of course a more pretentious handle

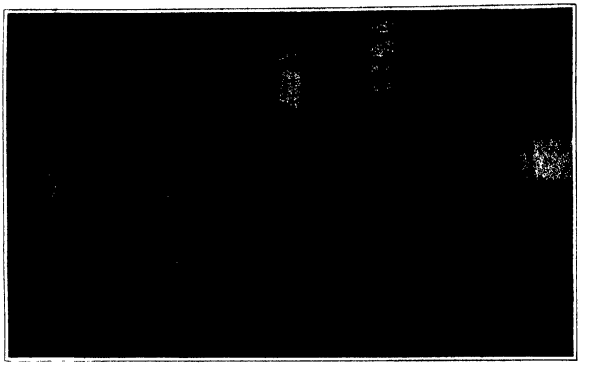
Hacksaw knife.

could be made from wood, held in place with rivets, but the handle described answers the purpose very well and has the merit of being made quickly. The blade is ground like an ordinary knife blade, or it can be ground on one side only like a chisel. If used for a scratch knife the latter method of grinding is preferred by the writer.

The First National Mine-Safety Demonstration

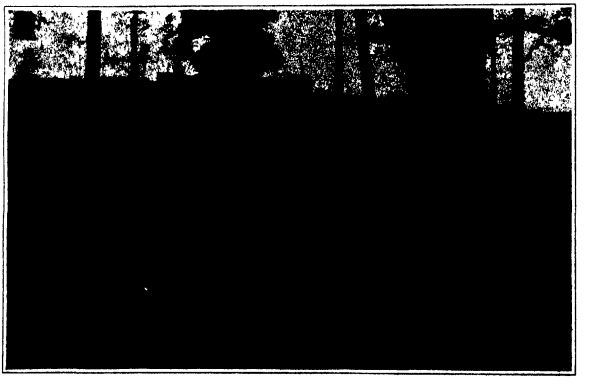
Study of a Real Mine Explosion

By Charles L. Wright, Fuel Engineer, Bureau of Mines



THE work that is being done by the Government to reduce the dangers of mining was brought out strikingly in the First National Mine Safety Demonstration which occurred at Pittsburgh, Pa., on October 30th and 31st, under the auspices of the United States Bureau of Mines with the assistance of the American National Red Cross Society and the Pittsburgh Coal Operators' Association

The work of the explosive testing section was exhibited in a spectacular manner in the gas and dust gallery which is a steel tube 100 feet long and 6½ feet in diameter open at one end and closed at the other, with the exception of a small hole through which it is fired by the flame from a small cannon charged with the explosive that is being tested The gallery is provided with explosion doors on top which are raised by the force of the explosion, and windows of heavy glass on the sides through which flame is visible when an explosion of gas or dust is produced A portion of the tube was partitioned off by heavy paper making a chamber in which gas and air were mixed so that the mixture contained seven per cent of methane and ethane, both explosive gases A charge of black blasting powder equal in strength to one-half pound of forty per cent nitro-glycerine dynamite was fired into the gallery igniting the gas and producing a terrific explosion Again, an amount of permissible explosive equal in strength to the black blasting powder was fired in a gaseous mixture of the same composition As no explosion of the gas took place, the relative safety of black blasting powder and permissible explosive was evident This test of explosives is especially valuable in gaseous mines where there is the liability that the flame from the explosive may ignite pockets of gas which may be present near where coal is being blasted out



In another building lighted by incandescent lamps were broken in an explosive mixture of gas and air illustrating the relative safety of lamps of different candle power when operated with different voltages In still another building a foundry cupola was in operation to show the method of taking gas samples and temperatures in various zones of the coke bed for the purpose of studying the fundamental principles of the process with a view to possible improvement A gas producer was in operation burning fuel at a high temperature and capacity and in which the ash and clinker were removed by tapping off the liquid slag at stated intervals

In the fuel briquetting plant two types of briquetting presses were in operation one of which was producing briquets from California lignite under a pressure of 20,000 pounds to the square inch without the use of artificial binder while the other machine made briquets of ordinary bituminous slack using six per cent of water-gas pitch as a binder These briquetting experiments have for their object the better utilization of fuel waste and low grade fuels

The long combustion chamber of the bureau was also interesting to many of the visitors This is essentially a Murphy stoker at one end of a long chamber built of brick and lined with fire brick at the other end of which is a water tube boiler At several points on this chamber there are openings for the insertion of thermo-couples and the withdrawal of samples of flue gas A large number of gas samples are taken from the various points simultaneously and the study of the analyses of these samples makes it possible to determine the proper distance that the furnace should be from the cold boiler tubes in order that complete combustion may take place This distance varies with different types of fuels and the results of these investigations will undoubtedly furnish valuable data for designers of boilers and furnaces

Long combustion chamber, showing apparatus for testing samples of gases at various points.

Entrance of the mine after the explosion. Note the debris.

THE FIRST NATIONAL MINE-SAFETY DEMONSTRATION

Another feature of the demonstration was a safety lamp test Single and double gauze safety lamps were placed in a testing apparatus where they were subjected to currents of air of a known velocity containing eight per cent of methane and ethane The lamps which were safe to use did not produce an explosion of this mixture of gas and air; others did, and thus their relative safety was demonstrated

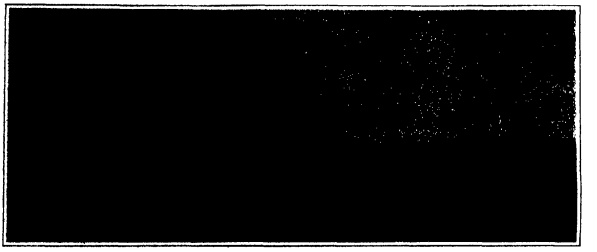
Men in various types of breathing apparatus were exercising in a room filled with a noxious atmosphere and a glass partition permitted the visitors to see in a graphic manner how operations are carried on by the rescue corps under conditions similar to those existing after an explosion has occurred in a mine.

There was also an exhibition of apparatus for the physical testing of explosives including a ballistic pendulum by means of which the relative disruptive forces of an explosive is determined; a pressure gage for determining the pressure developed by a known weight of an explosive; a calorimeter for determining the heat of combustion of an explosive; a flame testing apparatus for the determination of length and duration of the flame of an explosive, an apparatus for determining the rate of detonation of an explosive, a large and small impact machine for determining the force necessary to set off explosives, Trauzl and lead blocks which are also used for determining the relative power of an explosive and a cone and pendulum friction device for determining the behavior of explosives under friction

The explosibility of coal dust was shown by means of a laboratory coal dust ignition apparatus consisting of a heavy glass vessel into the bottom of which coal dust was blown by air upon a wire heated red hot by an electric current The force of the explosion of the coal was graphically shown by the bursting of a thin glass flask connected to the top of the ignition apparatus

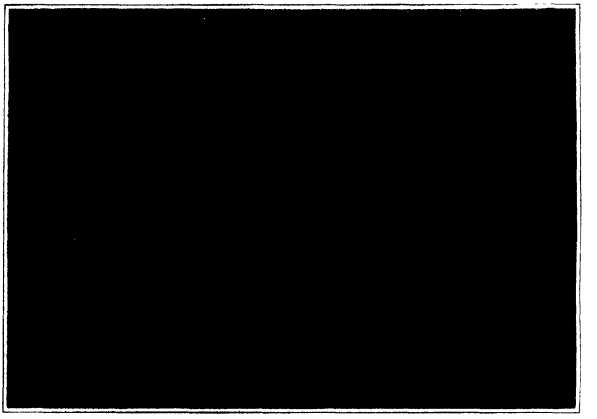
In gas and dust gallery No 2 an inclosed electric mine motor was shown operating in an explosive mixture of gas and air without producing an explosion Later the protecting devices were removed from this motor and an explosion of the gaseous mixture resulted The relative safety of motors for mining purposes under the two conditions open and protected were thus demonstrated

Two of the mine rescue cars of the Bureau were on the siding at the plant and open for the inspection of visitors



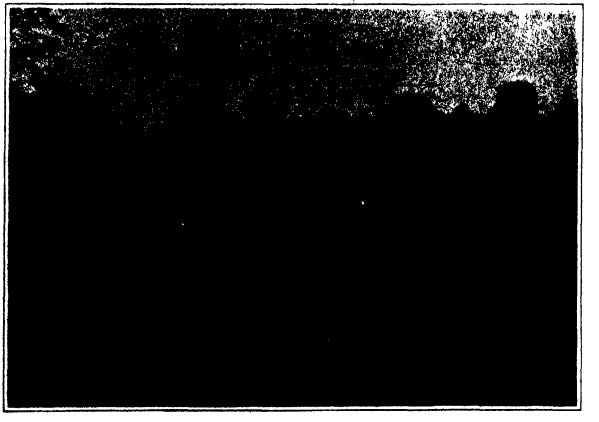
In the afternoon of the first day the experimental mine of the bureau was visited by a party of about two thousand people, a special train being provided The trip to the experimental mine was made for the purpose of seeing a demonstration of the explosibility of coal dust in a real mine. The mine is located in Bruceton, Pa., in the Pittsburgh seam of coal which at this point outcrops on the side of a hill about 100 feet above the railroad The mine was opened primarily in order to study the principles involved in dust and gas explosions and to test various methods of preventing and checking explosions in progress under actual mine conditions When the special train arrived at the station the rain was falling steadily, but this was not sufficient to dampen the ardor of the enthusiastic visitors including several ladies As soon as the party had climbed the steep ascent from the railroad to the mine they were invited to walk through the mine and 1,131 persons by actual count availed themselves of this opportunity. When all of the party were out of the mine again they were requested to take positions about twenty-five yards up the hillside above the mine

...t the explosion. Between 600 and 700 pounds of coal dust had been scattered along 600 feet of the main entry which is 750 feet long and two pounds of black powder were placed in a drill hole at the extreme inner end of the main entry in such a manner that the conditions would represent those similar to a blown-out shot in actual mining. Electric wires connected this charge of explosive with the instrument house outside of the mine The wires were placed in circuit with a source of electric current and the powder explosion which followed ignited the coal dust in the mine resulting in a terrific explosion It was dark by the time that the explosion occurred and the smoke and flame mounted high into the air above the entrances to the mine The air was filled with pieces of stone, broken concrete and wood and the people involuntarily took refuge under the trees There was no real danger, however, as the people were above and back of the mine entrances. The force of the explosion was manifested in the vicinity of the mine by the damage done Near the main entry a loaded mine car had been shot back about fifty feet while another partly loaded had been blown more than one hundred yards over a bank into the valley. The big bags of sand which were used in the brattices 130 feet from the entry had been blown out into the open The temporary fan house had been wrecked and the office building partly demolished If any of the mining men present had any doubt as to the explosibility of coal dust in a mine without the presence of gas, this question was settled once and for all



It had been planned to have men equipped with oxygen helmets enter the mine immediately after the explosion to take gas samples, extinguish incipient fires and inspect the condition of the roof, but the lateness of the hour made it necessary for all to hasten to the train waiting to convey them back to Pittsburgh

Every one who saw this demonstration was profoundly impressed with the importance of the test and many compliments were given to Director Holmes and those in charge of the experiment.



On the morning of the 31st the great first-aid meet and mine safety demonstration was held at Forbes Field. The first thing on the program was the first-aid exhibition. The forty teams that participated were arranged in a row facing the seats. While many of the teams participating came from Pennsylvania and adjoining States, there were others which came from longer distances notably those from Tacoma, Washington, Dawson, and New Mexico. The teams performed alternately in two sections, the even numbered teams working the same problems while the odd numbered teams worked other problems. The first-aid problems performed included treatment of lacerated wounds on the head and body, the treatment of fractured bones and dislocated joints, the removal of a man from an electric wire and the treatment of gas and electrical burns

A coal dust explosion in the gallery at Forbes.

Helmet man entering the gallery after the explosion.

Rescue squad bearing an injured man.

THE FIRST NATIONAL MINE-SAFETY DEMONSTRATION.

Following the first-aid work a demonstration of the behavior of a permissible explosive in the presence of coal dust was made in a temporary steel gallery or cylinder 133 feet long and 8 feet 4 inches in diameter The amount of explosive used was equal in disruptive force to one-half pound of forty per cent nitro-glycerine dynamite The explosive was fired into the gallery from a cannon through a small opening in the steel end of the former The other end was open to the atmosphere One hundred and thirty-three pounds of coal dust was distributed uniformly throughout the explosion gallery and twenty pounds of dust was placed on a wooden bench twenty feet long near the mouth of the cannon making a total of 153 pounds of coal dust When all was ready the charge was fired from a distance through wires by means of a storage battery No explosion of the coal dust was produced by this test which demonstrated the safety of using a permissible explosive in the presence of dust A second demonstration was made in the same gallery with the same amount of coal dust using a charge of FFF black blasting powder equal in disruptive force to the permissible explosive used in the previous test When this black blasting powder was ignited from a distance a tremendous explosion took place, the flame escaped from the safety doors on top of the cylinder and great clouds of dust and smoke were blown out of the end of the gallery

Immediately following this explosion while the gases within the gallery were still unbreathable a rescue party of foremen miners of the Bureau of Mines aided by squads from some of the visiting first-aid teams and all of them equipped with various types of breathing apparatus, entered the gallery and recovered several supposed victims of the mine explosion bringing them from the explosion gallery and placing them in the care of squads of foremen miners and first-aid miners of the Bureau of Mines who demonstrated the various first-aid problems using the pocket first-aid packet only and such things as might be handy in a mine after an explosion

Another interesting feature of the exhibition was the mine gas test made with the use of birds in exploring mines after explosions or mine fires at which carbon monoxide causes a large percentage of fatalities Birds are much more sensitive to the effects of this poisonous gas (carbon monoxide), than human beings, and when birds taken with a rescue party into a mine show signs of distress the party (which of course is supposed to be without oxygen helmets) will ordinarily have time to retreat to safety At Forbes Field the practicability of this test was demonstrated by a gas chemist of the bureau who entered a glass box about 2 feet wide by 5 feet long, and 6 feet high with canaries in cages The atmosphere of the box contained one quarter of one per cent of carbon monoxide gas (the miner's white damp). In eight minutes three of the birds were overcome and collapsed completely

The Heavens in December, 1911

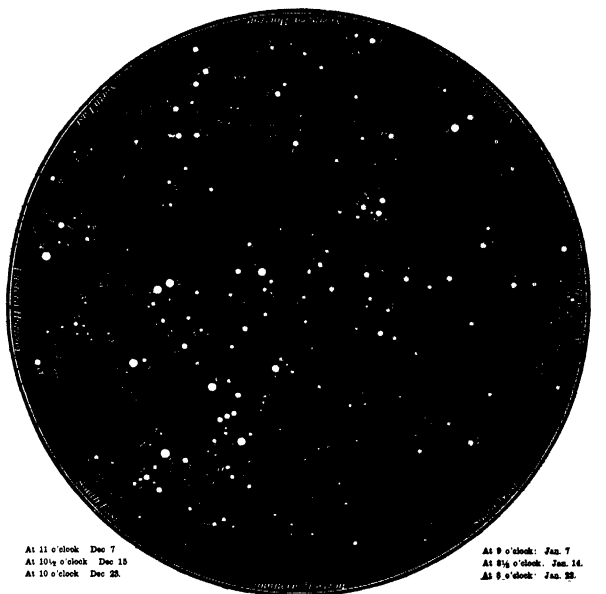
By Henry Norris Russell, Ph.D.

WE had occasion not long ago to speak of the interesting observation of Prof Stebbins of the University of Illinois, who devotes his time to making very accurate measures of the brightness of the stars, with an apparatus depending upon the change in the electrical resistance of selenium when light falls on it Not content with the study of known variable stars, Prof Stebbins has taken up the work of discovery, with conspicuous success, finding two new variables in the first two stars observed.

As, on the average, perhaps one star in a hundred, at most, varies in brightness, some principle must have guided such a successful search

Spectroscopic observation tells us that many bright stars are really close doubles, far too near together to be separated by the most powerful telescopes, but revealed by the approach or recession of the star as it swings in its orbit about the center of gravity of itself and a companion

In a few cases, such as Algol, the faint and relatively dark companion comes in front of the brighter star at every revolution and eclipses most of its light, causing conspicuous changes of its apparent brightness



The amount of light variation in such a case obviously depends on the character of the eclipse If the companion passes almost squarely in front of the primary, it will eclipse the greater part of its area, and, indeed, may completely hide it if, as often happens, the former star is the larger But if it passes apparently to one side of the brighter star and, even at most, covers up but a small portion of the latter, only a little light will be lost by the eclipse, and the apparent variation will be small, and can be detected only by very accurate measures

Observing the brightness of selected spectroscopic binaries of this sort, Prof Stebbins has found that the bright stars Beta Aurigæ and Delta Orionis are eclipsing variables of the type just described He defers full discussion of the latter until more observations have been secured, but his conclusions regarding the former are presented in definite form

Beta Aurigæ was one of the first spectroscopic binaries discovered Careful study by several observers has shown that the system consists of two stars of very nearly equal mass and brightness, revolving at equal distances on opposite sides of their common center of gravity, in a circular orbit, within a period of about an hour less than four days Prof Stebbins finds that, just at the times when, according to the spectroscopic data, either star ought to be in front of the other, the apparent brightness of the system diminishes by about 7 per cent This shows that a partial eclipse takes place, one star covering up about one-seventh of the other, cutting off that fraction of its length, and hence one-fourteenth of the total light of the pair These eclipses last a little less than six hours

Between the eclipses the brightness of the star is not perfectly constant, but increases by about 1 per cent until the time halfway between eclipses, and then falls again to its original value, just before the next eclipse This may be explained by assuming that the mutual attraction of the two stars causes them to be slightly elongated toward one another, like two eggs with their narrow ends pointing at each other! When the stars are just out of eclipse, we see them end on

A day later, midway between eclipses, they are broadside on, and look correspondingly brighter. The amount of this elongation is, however, only 1 per cent of the whole diameter, which could hardly be detected on a drawing to scale From the length and depth of the eclipses, it is possible to find the inclination of the orbit plane, and the diameters of the two stars, in terms of that of the orbit The spectroscopic observations then furnish us with a reliable scale of miles, and enable us to calculate the actual dimensions and mass of the system. What is more, in this case the parallax of the star is fairly well determined, both by direct measures and because it belongs to the group of stars moving together in space, of which the principal stars in Ursa Major are members. He can, therefore, compute the actual brightness of the stars, compared with the sun

NIGHT SKY: DECEMBER AND JANUARY

Combining all these facts, we reach a knowledge of the system more extensive than we at present possess for any other star We may summarize it as follows.

Beta Aurigæ consists of a pair of stars of equal size and brightness and very nearly equal mass, which revolve about their common center of growth in circular orbits lying in a plane inclined 12 degrees 49 minutes to the line of sight, with a period of 3 days 23 hours 2 minutes and 30 seconds, and mutually eclipse one another at every revolution. The two stars are elongated toward one another by their mutual attraction to the extent of 1 per cent of their diameters, and, owing to the influence of the tides raised by each on the other, the period of revolution is increasing by seven-eighths of a second every year.

The actual distance between the centers of the two stars is 7,630,000 miles, and each star is 2,200,000 miles in diameter The more massive component has 2.38 times the mass of our sun, and the other 2.34 times.

The whole system is at a distance of about ten million times that of the sun—so great that light takes 160 years to travel over it Each of the two stars gives out about 130 times as much light as our sun, from a superficial area a little less than seven times as great, so that per square mile, these stars send out nearly twenty times as much light as does the sun

The sun itself, if in front of one of them, would appear as a rather small and very dark spot on the star's surface.

Though there is no other individual star about which we know nearly as much as this, it is probable, from various lines of evidence, that Beta Aurigæ is a fairly good representative of a considerable class of the brighter stars—which emphasizes the fact that our mighty sun is, after all, one of the smaller members of the host of heaven.

The Heavens.

Turning our gaze overhead, we find Auriga close to the zenith. The brilliant Capella may serve as our landmark. Beta Aurigæ is close by on the east, almost in the line toward Castor and Pollux, which are conspicuous at an altitude of about 45 degrees. Procyon shines on the right, lower down, and Regulus, with the Sickle of Leo, is rising a little north of east.

In the southeast is the magnificent group of constellations centering in Orion Sirius, still lower down, but surpassing all other stars in brilliancy, so outshines the other stars of Canis Minor that it is only when we hide him from view that we realize that some of them are as bright as the stars of Orion's belt High up near the zenith is Taurus, now made conspicuous by the ruddy Mars, which exceeds even Sirius in brilliancy.

The constellation of the Hare and the Dove, below Orion, though small, contains more stars of fair brightness than does the vast extent of the sky to the westward, occupied by the winding course of Eridanus. Cetus, farther to the right, is more conspicuous

Due west from the zenith we find Perseus, then Andromeda, and finally Pegasus Between these last and Cetus are the little triangle of Aries and the extensive but inconspicuous constellation Pisces

This is the faintest of the zodiacal constellations, except perhaps Cancer, but makes up for this by some faint resemblance to the two fishes bound together by a cord, which are its traditional likeness.

This cord, or rather cords, start at Alpha Piscium, a fairly conspicuous star of the fourth magnitude, pointed out by a line from α and through γ Ceti. From this one line of faint stars runs northward toward β Andromedæ to the Northern Fish, which is represented by a group of faint stars south of β Andromedæ Another and rather more conspicuous line of stars runs west from α Piscem for about 30 degrees to the Southern Fish, whose body is marked by an irregular polygon of small stars south of the great square of Pegasus Our initial letter shows the general arrangement of the constellation.

In the northern sky) Cassiopeia and Cepheus are on the left of the Pole, Ursa Minor and Draco below, and Ursa Major coming up on the right

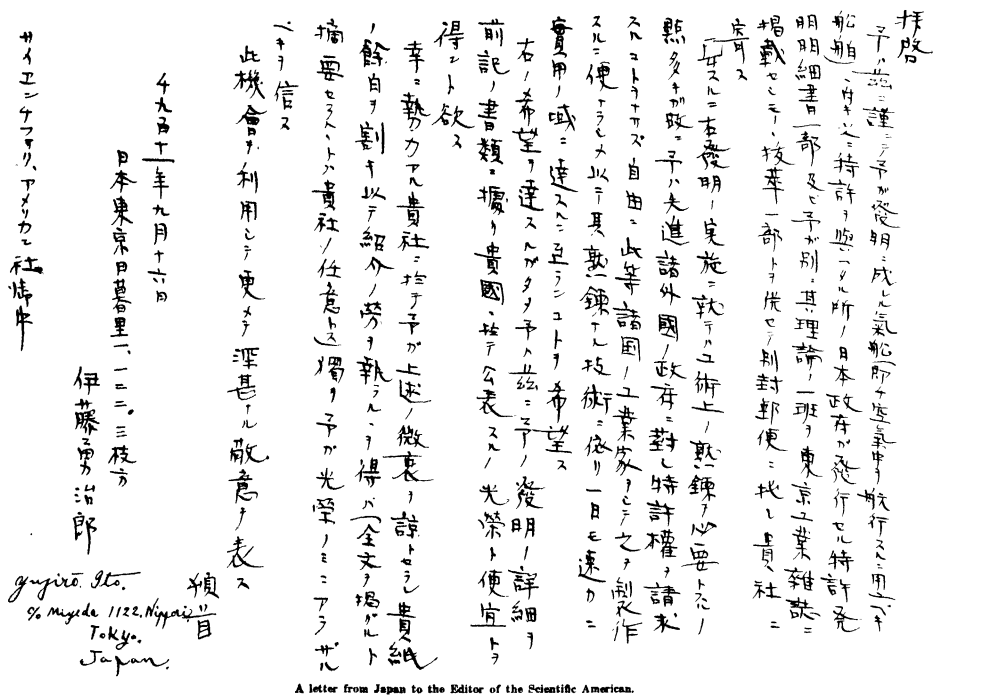
The Planets.

Mercury is evening star until the 25th, and afterward morning star. He is apparently farthest from the sun on the 7th, but, being very far south, is unfavorably placed, and sets about 5:40 P. M.

Venus is morning star, very conspicuous and brilliant, rising about 3:10 A. M. on the 1st, and 4 A. M. on the 31st She passes eastward and southward from Virgo almost into Scorpio during the month, and, telescopically, appears like the Moon two days past the first quarter. Mars is in Taurus, just past opposition.

(Continued on page 506.)

The Inventor's Department



Simple Patent Law; Patent Office News; Inventions New and Interesting

A Letter from Japan.

THERE is scarcely a nook from the Straits of Magellan to Alaska, and from Siberia to the Cape of Good Hope, that is not reached by the SCIENTIFIC AMERICAN. Hence it follows that the Editor's mail includes letters from all quarters of the earth. The questions asked him run from the classic problem of the hare and the hunter to the request for a formula for trisecting an angle. As a rule, these letters are written in English or in one of the familiar European languages. Occasionally the Editor is puzzled by a letter written in characters which are beyond his use with their expert technique, without delay.

"In order to fulfill my desire, I wish to have the honor and facility of having the details of my invention made public in your country by the papers I am submitting you. I shall feel greatly honored if your esteemed firm gives consideration in this matter and has the kindness to introduce my invention in your valued magazine. I will leave it entirely to your own convenience whether you use the full text or its outline. With great respect, I remain, Very truly yours,

"YUJIRO ITI."

A letter from Japan to the Editor of the Scientific American.

ken. Only the other day a communication was received from Japan, which is reproduced herewith for the benefit of those who may prefer to read it in the original. Needless to say, the Editor had to ask a Japanese friend for the following translation:

"THE SCIENTIFIC AMERICAN:

"Dear Sirs: I am sending you under separate cover, a copy of patent specification published by the Japanese Government, for an airship invented by myself and for which patent was awarded, also a cutting from *Tokyo Kogyo Zasshi* (*Tokyo Industrial Magazine*) to which I had contributed a portion of the theory.

"As a matter of fact, technical skill is necessary in the practical application of this invention, therefore, I am not going to secure patents from the governments of progressive foreign countries, but my desire is to facilitate the manufacturers of those countries in manufacturing my invention and in putting it into practical

The Japanese patent referred to is in the Editor's drawer, and he will be glad to show it to any one who thinks he can make use of the invention.

The Original Organic Patent Act

THAT our forefathers realized the importance of inventions and appreciated the part they would play in the development of our material resources, is shown by the serious attention paid, in framing the constitution, to the patent and copyright clause and the early enactment of the organic patent act of April 10th, 1790, by the Congress. The Departmental proceedings under this act, looking to the grant of patents, is interestingly told in the following extract from the *Patent Official Gazette* of October 9th, 1877:

By act of April 10th, 1790, the first American patent system was founded. Thomas Jefferson inspired it, and may be said to have been the father of the American Patent Office. He took great pride in it, it is said, and gave personal consideration to every application that was made for a patent during the years between 1790 and 1793, while the power of revision and rejection granted by that act remained in force. It is related that the granting of a patent was held to be in these early times a weighty event in the history of the State Department, where the clerical part of the work was then performed.

It is a matter of tradition, handed down to us from generation to generation by those who love to speak of Mr Jefferson and his virtues and eccentricities, that when an application for a patent was made under the first act, he would summon Mr Henry Knox, of Massachusetts, who was Secretary of War, and Mr Edmund Randolph, of Virginia, who was Attorney-General, these officials being designated by the act, with the Secretary of State, a tribunal to examine and grant patents; and that these three distinguished officials would examine the application critically, scrutinizing each point of the specification and claims carefully and rigorously. The result of this examination was that during the first year a majority of the applications failed to pass the ordeal, and only three patents were granted. In those days every step in the issuing of a patent was taken with great care and caution, Mr Jefferson seeking always to impress upon the minds of his officers and the public that the granting of a patent was a matter of no ordinary importance. During 1791, thirty-three patents were granted, in 1792 eleven, and in 1793 twenty, making sixty-seven under the first statute.

New Roof for Patent Office Building

THE Patent Office has just been supplied, at a cost of something like four thousand dollars, with a new roof of slag replacing one that has served as a covering for the building ever since the great fire of 1877. It is interesting to compare the difference in cost between the new roof and the old. The one just removed was of sheet copper, but was found to be fairly riddled with holes and cracks from exposure to the elements for more than thirty years. The copper roof cost in the neigh-

Emery Disappearing Carriage

IN the 21st report (October 31st, 1911) of the Board of Ordnance and Fortification to the Secretary of War, we find a reference to the Emery disappearing car-

riage In the report the Board says "There have been no developments, so far as the Board is informed, in connection with the Emery gun carriage, and the board can only repeat what has been said heretofore in regard to the history of this carriage All the work on the Emery design has been done under direct legislative enactment, and the only part to be taken by the Board in the matter is that, when completed, if ever, the carriage is to be tested under its supervision" The report goes on to refer to the several special acts of Congress, beginning with that of February, 1893, and appropriating $130 000 up to the Act of May 27th, 1908, and concludes its reference to the matter as follows In its last annual report the Board stated that 17 years had elapsed since the construction of a carriage of Emery's design was first authorized This remark may now be varied by saying that 18 years have passed and the government still has nothing to show for the expenditure of 95 per cent of the appropriations except the foundations for the carriage which were put in three years ago in order to enable Mr Emery to obtain an additional $5,000 as provided by the act of 1908, practically the first which required him to do anything in return for money paid him "

According to the report, of the $114,443 02 available for the execution of the present contract with Mr Emery for his carriage, $100,811 51 has been paid him, and the report says

"There may be added to the $114,000 mentioned above the sum of $137,656 98 paid under the first contract, which was canceled by congressional authority, so that the total amount authorized has been a quarter of a million dollars Of this sum there remains to be paid Mr Emery $13,531 51, or slightly more than 5 per cent of the total amount authorized "

The Board includes seven Army officers headed by Leonard Wood, Major General, Chief of Staff, President of the Board and one civilian member, William Warner

Notes for Inventors

A Lamp Dimmer for Motor Cars.—The extremely brilliant and dazzling head lights of motor cars are at times very objectionable and some municipal regulations forbid their use Warren A Greenlaw of Melrose, Mass, provides, in a patent (No 1,005,197) for dimming the lamp by sliding the burner away from the strong focal or reflecting point in front of the reflector To do this, he supports the burner so that it can slide longitudinally and utilizes fluid pressure to move the burner from its normal position This enables the driver of the car to dim his light whenever desired by sliding it out of its focal relation to the reflector

Novel Wrench—In patents No 1,004,561 and No 1,004,562, William Henry Joseph Fitzgerald of Braintree, Mass, shows a wrench in which the shank carrying the fixed jaw is tapered, reducing toward the fixed jaw, the sliding jaw has a tapered shank sliding on the shank of the fixed jaw and a yoke encloses both tapered shanks and can be conveniently set to secure the sliding jaw in any desired adjustment

Lubricating Air Brakes.—Edwin A Emery of St Louis, Mo has patented (No 1,004,000) a lubricating means for fluid pressure brakes in which is provided means for charging the air in the train pipe with a lubricant A pipe connects the exhaust port of the triple valve to the chamber at the non-pressure side of the brake cylinder piston in order to vent the lubricant laden air released from the brake cylinder to the said non-pressure chamber to lubricate such chamber

Novel Initiating Apparatus Some secret societies employ many mechanical aids in connection with their introduction of new members Such a device is shown in patent No. 1,004,857, and presents the appearance of an ordinary platform scale The platform, however, is collapsible and as it falls, operates an alarm mechanism The candidate by moving the scale beam releases locking devices and the platform on which he is standing falls and sounds the alarm The patentee is Ernstus De-Moulin of Greenville, Ill

Preserving Corn With Tar.—To preserve corn in the ear and with the husk on is the purpose of patent (No. 1,004,033) to Benjamin F Johnson of Macclenny, Fla In doing this, he ties the husk beyond the tip end of the ear with twine and then submerges it in pine tar A coating of dust is then applied after which it is plunged into air slaked lime

Advertising Novelty.—Robert Klotz of Chicago, has patented (No 1,004,660) as an advertising novelty, a device including a head having a pivoted jaw and a movable tongue Associated with these is a drawer which can be utilized for any purpose and means are provided so that the movement of the drawer operates the jaw and tongue of the head

New Vulcanizing Process.—John R Gammeter of Akron, Ohio, assignor to B F Goodrich Company, same place, has patented (No 1,004,865) a method of vulcanizing in which the tubing to be vulcanized is inflated and a band is wrapped spirally around the tube, the wrapped portion being simultaneously fed through a vulcanizer at the same rate the band is applied, and unwrapping the band from the vulcanized portion

Fly for a Coat —Ordinarly garment flies are open at the edge Abraham D. Goffin of New Haven, Conn in a patent (No 1,004,869) presents a garment fly which has a closed edge the inner flap of the fly having a button hole formed through it and the same flap has a slot through which the finger may be passed in buttoning and unbuttoning the garment, thus avoiding the necessity of having the fly open at its outer edge

Increasing Relative Amount of Hydrogen in Hydrocarbons –Dr David T Day, the well-known petroleum expert of Washington, D C, has patented (No 1,004,632) an apparatus for treating hydrocarbons in which an intermediate oil chamber connects with one of the vapor chambers and tubes connect the vapor chamber through the oil chamber, the purpose being to produce hydrocarbons containing more hydrogen than before, in proportion to the amount of carbon, and in doing this the hydrogenating tubes are immersed in the body of oil which is being distilled and are heated by the oil to a temperature as high as or greater than that of the distillate vapors, thus utilizing the heat of the oil for superheating the commingled hydrogen and oil vapor and effecting saturation of oil with hydrogen, the saturated vapor passing off to an outlet chamber and thence through a goose neck to the condenser

Legal Notes

Assignment by Trustee in Bankruptcy.—In deciding Ex p Eyton O G, 171, pg 481, the Commissioner of Patents, in denying that portion of the petition which asked that the patent, when granted, be issued to the assignee as requested, said

"To investigate the laws of various foreign countries in order to determine the titles to applications for patents pending in this office filed by foreigners who have subsequently become bankrupt would place an enormous and unnecessary burden upon the office Since it is unquestionably proper to issue the patent in the name of the applicant, this is believed to be the safe rule in such cases In the present instance petitioner has not shown that any hardship would result from following this plan "

In the Hubert case, decided September 11th, 1911, published October 17th, 1911, the Commissioner of Patents held that if an assignment be of record, transferring the entire right, title and interest without any qualifications or reservations, and said instrument contains a request to issue the patent to an assignee, such action will be taken by the office, even if licenses be also of record Also that a patent will not be issued in accordance with the request contained in an alleged assignment which is made subject to any exclusive license.

Conflicting Patent Decisions.—Two interesting decisions, handed down in different districts of the Seventh Circuit, have recently been published. The state of facts in both cases was practically identical, that is infringement of the Claude and Hess patent (No 664,383) and the effect upon this patent of the inventors' English patent, dated June 30th, 1896, which expired by limitation June 30th, 1910 This patent concerns the use of acetone as an absorbent for compressed acetylene and appears practically to dominate the packaging of acetylene in cylinders in this country. The important claims in this patent cover a so-called gas package, while the English patent relates to the process The defendants contended that the two patents were for the same subject-matter and that, under the provisions of Sec 4887 R S, the American patent expired with the English. Judge Kohlsaat decided that they were for the same matter and denied an injunction (See 188 F R 85) Judge Dennison, a few weeks later, held that the two patents were for different subject-matter and that, according to the Leeds & Catlin case, 213 W B 301, the American patent was still in force (see 188 F R 89)

Presumption in Reissue that Law was Complied With.—In the case of the John Kitchen, Jr, Company v Levison (Circuit Court of Appeals, Ninth Circuit, July 3rd, 1911, 188 Fed Rep 638) the Court said, "From the reissuance of the patent it is to be presumed that the law was complied with and the proceedings can only be impeached for fraud," quoting Seymour v. Osborne, 11th Wall 516-543.

Mileage Ticket Decision.—In the case of Rand, McNally & Company, in the Circuit Court of Appeals, Seventh Circuit, January 10th, 1911, rehearing denied April 11th, 1911, the Court held that the Richardson & Langston patent (No. 699,489) for a script book, containing a series of coupons to be detached and exchanged for passage-tickets, the essential feature of which is that the units are expressed in money instead of in miles, as in the ordinary mileage tickets, which adapts them to more convenient use on transportation lines having different rates, disclosed patentable invention, and is valid, also held infringed In this case District Judge Carpenter filed a strong dissenting opinion

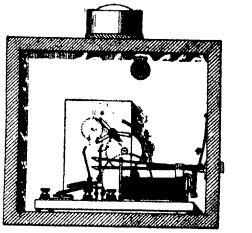
A Warning from the Bench.—It is not often that a judge on the bench will give a general warning to practitioners such as that given in the Court of Appeals of the District of Columbia in the case of American Stove Company v. Detroit Stove Works, and Barstow Stove Company Barstow Stove Company v. Detroit Stove Works, and American Stove Company In the decision, Mr Justice Robb in his usual clear and forcible manner, said.

"We have observed a tendency on the part of patent attorneys to disregard the rules of evidence by asking questions more or less leading and suggestive, and it may not be amiss to state that, where timely objection is noted in the record, this court will be disposed to apply the rule and entirely disregard such testimony The witness instead of giving his independent recollection of past events becomes, by this practice, a mere echo whose recollection stimulated by leading questions keeps pace with those questions. The practice is objectionable and subversive of justice, and should be stopped."

"Penny a Pound Profit."—In the case of *ex parte* Loft, Asst Commissioner of Patents Tenner holds that writing a descriptive word in a distinctive manner does not render it registrable as a trade-mark and that the phrase "Penny a Pound Profit" is discriptive as applied to candy. In reaching his conclusion the Asst. Commissioner says the phrase is in his opinion clearly descriptive of the quality of the goods and is also of an advertising character.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. Notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.



Pertaining to Apparel.

SUNSHADE.—R F. BICKERTON, 924 New York Avenue, Washington, D. C. This shade is designed for use in shielding the wearer from the sun at ball games and other athletic sports, fishing and the like; and the object is to provide a shade easily applicable to an ordinary hat and can be adjusted to any desired position around the hat in order to properly protect the wearer from the sun.

SKIRT MARKING DEVICE.—F B DAVENPORT, 38 Welles Building, Wilkes-Barre, Pa. The intention in this case is to provide a device arranged to permit convenient marking of a skirt along the lower end, with a view to obtain an accurate bottom line a desired distance above the floor, and to permit of observing after the skirt is finished, whether the bottom edge is the desired distance from the floor

Electrical Devices.

PARTY LINE TELEPHONE SYSTEM.—EDWARD STOUT and JOSEPH E KUPKA, Stockfort, Iowa In this case the more particular purpose is to produce a reliable system in which the number of telephones may be considerable and in which the selectivity of the particular station or stations to be called is rendered comparatively certain Provision is made for calling one or any larger number of subscribers, to the exclusion of all other subscribers upon the line The system further compre-

PARTY LINE TELEPHONE SYSTEM.

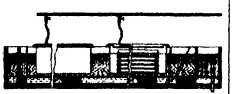
hends means whereby a single station may call up simultaneously all other stations on the line It also relates to lock-out mechanism, whereby when any two or more stations are connected up for talking, all other stations are excluded and are unable to interfere with business being transacted over the line The engraving shows the electrically-operated contact mechanism forming part of the switch and controlling various circuits

TRANSFORMER SYSTEM.—H C CAMPBELL, Fort Michie, New London Conn. This invention relates to transformer systems, the more particular purpose being to provide such a system in which a peculiar advantage is taken of the fact that time is required for the magnetic field to flow, under the influence of variations in the exciting electric current

Of Interest to Farmers.

SHOCK LOADER.—G H TARVIN, care of A Arrowsmith, L B 104, Slocum, S D This invention relates to a loader adapted to run along the field and pick up a shock of hay or grain and deposit it in the wagon rack carried therewith It provides a device with a fork adapted to scoop a bundle of grain or a pile of hay off the ground, and an auxiliary swinging fork adapted to remove the material from the fork and deposit it in a rack

CORN PLANTER.—M H BIRD, Sandersville, Ga The main object here is to provide means for feeding the corn at stated intervals. To this end a hopper is arranged having a sliding feed mechanism adapted to be operated by a colter wheel The hopper and feed mechanism are loosely connected to the main frame so that when an obstruction is met, the feed mechanism may rise to pass over it, automatically settling again into the furrow when the obstruction is passed

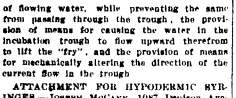


Of General Interest.

ROOF FRAMING SQUARE.—H. H. CRISS, P O Box 604, Globe, Ariz. This invention is an improvement in roof framing squares, and the object of the inventor is to provide a simple device by means of which rafters of all kinds may be laid off with absolute correctness, and without the necessity of any calculation upon the part of the user

FACIAL MASSAGE APPARATUS.—G. C. BUCK, 81 Highland Avenue, Minneapolis Minn. This apparatus is for use in applying hot water to the face, and is an improved substitute for hot-towels commonly used for facial treatment. It includes a water pan or open-top receptacle having attachments for in-

and outflow of hot water, and a device ted to be held in the mouth for supplying to support respiration while the face is d immersed in the water in the pan.



TROUGH FOR FISH HATCHERIES.—FRANK PARRY, 19 Beatrice Street, Toronto, Canada. The engraving herewith shows a ventical section of a hatchery trough constructed and arranged in accordance with the present invention, which has for its principal objects the provision of means for subjecting the "fry" while in the trough to the action

TROUGH FOR FISH HATCHERIES

of flowing water, while preventing the same from passing through the trough, the provision of means for causing the water in the incubation trough to flow upward therefrom to lift the "fry", and the provision of means for mechanically altering the direction of the current flow in the trough

ATTACHMENT FOR HYPODERMIC SYRINGES.—JOSEPH MCCANN, 1087 Denison Avenue, Columbus, O. In this invention the improvement is in syringes in which the needle is inclosed and protected by a cap that is detachably connected with the body or barrel of the instrument. The attachment is shown in the engraving in connection with the

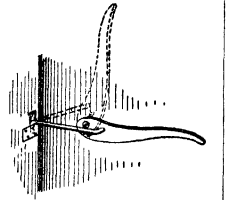
ATTACHMENT FOR HYPODERMIC SYRINGES

syringe. It comprises the detachable needle-cap, a cone containing extra needles and wires for cleaning them, and a safety pin, for fastening, these parts being connected by chains, so that the case, cap, and syringe proper in which the cap is applied when the needle is not required for use, may be all suspended from the clothing of the physician or nurse and thus may be available for instant use

RESPIRATOR.—W I COOKE, Port Washington, L I, New York This invention comprehends a mask to be applied to the wearer's face and held in position by a strap or the like, a flexible tube connecting the mask with the outer atmosphere through the medium of an inlet valve; the mask being further provided with an outlet valve for discharging the air as the same is breathed

PHOTOGRAPHIC MAGAZINE CAMERA.—B GOLDSTEIN, 330 East 120th Street, New York, N Y This camera is arranged for day light loading and for quickly and successively discharging the exposed sensitized plates from the camera into a tank filled with a developing fluid, and for preventing the plates from being light struck while in the camera or while being transferred from the camera to the tank

NON-REFILLABLE BOTTLE.—STEVE O STAMOS 501 East Eighth Street, Anaconda, Mont. This invention provides a bottle having a neck of the shape shown in the engraving Fitting tightly in the neck a closure has an opening for the reception of a cork, this opening communicating with the interior of the bottle by means of a passage having three valve seats A by-pass communicates at

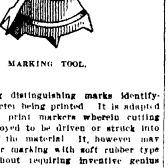


NON-REFILLABLE BOTTLE.

its top with the upper portion of the passage, but is normally cut off from the lower portion of the passage by means of a thin glass plate. Above the valve seat at the top of the passage is a valve while in the upper portion of the by-pass is a ball connected to the valve by means of a thin glass strip These novel means permit the outflow of the liquid, but will prevent introducing a liquid into the bottle.

Hardware and Tools.

HASP FASTENER.—A H BROWNE, R F D, No 6, Lebanon, O This fastener is for use on hinged and sliding doors In the engraving it will be seen that during the operation of bringing down the lever the drawer is drawn tightly against the frame and at the same time securely locked The door is thus not only secured, but a weather-proof joint is formed between it and the frame, so

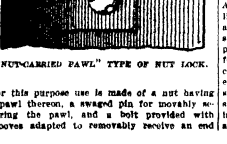


HASP FASTENER

that it cannot be rattled by the wind and the entrance of moisture is effectually prevented It may is made in rights or lefts for the application of the right side or left of a door frame It is particularly applicable to doors of tobacco barns and similar buildings requiring ventilation, since by employing different keepers the door may be held open more or less and yet securely

PAPER HOLDER FOR SCALES.—L E ZIMMERMAN, 605 N 7th street, Pekin Ill An object here is to provide an attachment to hold a paper covering upon the scale plate, thereby keeping the plate clean and in a sanitary condition The attachment holds the paper firmly in position and yet is out of way of the article so that the latter can be placed on the plate in the usual manner

SPRING HAMMER.—J H PHILLIPS, care of T B Anderson Construction Co., 24 Main Street, Oklahoma, Okla This portable hammer is for shop or field work, and is adapted to be used in various operations, such as riveting, punching, calking, shearing spike driving, stone, brick and concrete drilling, etc This automatic trip hammer receives its motive force from a compressible spring the latter having means thereon whereby the tension may be adjusted

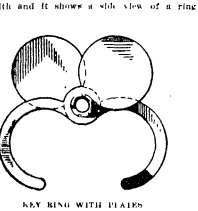


MARKING TOOL.—JOSEPH A WICKES, 54 Broadway, East Somerville, Mass The marking tool illustrated herewith represents an invention, which has in view to provide a tool with marking faces having corresponding oppositely extended distinguishing features; and to provide in a marking tool a plurality of hammer

MARKING TOOL.

heads bearing distinguishing marks identifying the character being printed It is adapted for punch or print markers wherein cutting dies are employed to be driven or struck into the surface of the material It, however, may be adapted for marking with soft rubber type and this without requiring inventive genius or act

NUT LOCK.—H T EARLES, Mount Morris Pa This invention relates to nut locks, more particularly to the "nut carried pawl" type, and has for an object to provide a device of this class for removably securing a nut to a bolt to prevent the nut from being released from the bolt by any vibration or the like



"NUT-CARRIED PAWL" TYPE OF NUT LOCK.

For this purpose use is made of a nut having a pawl thereon, a swaged pin for movably securing the pawl, and a bolt provided with grooves adapted to removably receive an end of the pawl to secure the nut to the bolt The illustration gives a view looking at the end of the bolt and showing the nut lock secured thereto

PAPER CUTTER.—M TAUSONE, P O Box 405 Ouray, Colo This invention is an improvement in paper cutters and especially in that class of cutters wherein the paper is supported in the form of a roll and is drawn from the roll as used and is cut off in the desired lengths Means provide for securing a clean cut in tearing the paper off along the blade

LOCK.—M G JASONITA 1140 First Avenue, New York, N Y This invention has for its purpose the provision of a lock wherein the bolt will be released and assume an unlocked position when a key is inserted in the lock in the usual manner to operate the same Besides being secured to the side of a door the lock can be employed in any convenient manner such as a mortise lock on the like

KEY RING.—CHARLES SCHUMACHER, 713 First Avenue, N S, Pittsburgh, Pa Among the principal objects which the present invention has in view are to provide a ring having arms frictionally held to form a ring, to provide a pivoted member for attachment to a chain, and to provide a device of the construction set forth with a plurality of advertising plates two of which are covered during the major portion of the time The device is illustrated herewith and it shows a side view of a ring

KEY RING WITH PLATES

in open position The solid plates at the top are employed as a means for advertising articles and for imprinting thereon the name and address or other information relative to the owner to serve as a partial identifying article The inventor invites correspondence in reference to the sale of this improvement

Heating and Lighting.

LAMP ATTACHMENT.—H LEHMANN, 9114 Washington Street, Waco, Tex This invention has reference to lamp attachments and the object is to provide a device for use in preventing lamp explosions, to serve as a means for heating liquids over a lamp and to prevent the cracking and breaking of lamp chimneys

Household Utilities.

AUTOMATIC DISINFECTING DEVICE.—T F HARVEY, 78 Webb Street, Chelsea, Mass The present invention has reference to an automatic liquid disinfecting device, which is adapted to be attached to the flushing tank of a water closet, whereby a certain amount of disinfectant may be supplied to the water in the tank each time the tank is operated

Machines and Mechanical Devices.

WASHING MACHINE.—E KOHAN, Port Ewen N Y This apparatus will wash clothing without rubbing, whether mechanically or by hand It cleanses simply by the physical action of running water and air, the water carrying a proper amount of dissolved soap and it cleanses gently but thoroughly without the wear and tear usually met with when clothing or the like is washed by hand or laundried by machines

SAFETY GATE FOR ELEVATORS.—H L BRAYTON 225 South Howell Street Owosso Mich This improvement relates to means for opening and closing elevator gates automatically by the movement of the elevator cage or car, and the aim is to provide a mechanism which will be located entirely in the elevator shaft readily accessible in all its parts and which will not require any counter weights

CALF WHEEL.—T A BEECHER, Taft, Cal In this patent the invention has reference to artesian and oil wells, and has for its object to provide a wheel and shaft for use in raising and lowering casings into drilling wells and as known among those skilled in the art of well drilling, a further object is to keep the casing loose

COMBINED BULL WHEEL, TUG WHEEL, AND MOUNTING REEL THEREFOR.—T A BEECHER, Taft, Cal This invention provides a construction to withstand shocks to which structures of this character are subjected provides to facilitate a division of the reel for winding the cable whereby a plurality of cables may be employed, provides a structure evenly and firmly keyed to the supporting shaft to distribute torsional strains of the structure, and provides means for readily truing the bearing of the structure on the shaft and to eliminate vibration from the structure.

MEANS FOR TEACHING AVIATION AND TESTING AEROPLANES.—W F MANGELS, Coney Island New York, N Y A means is provided in this invention to enable a person to acquire with the utmost safety all the necessary skill and confidence required for a flight in the open air with an aeroplane or other flying machine and to allow aviators to fully test the motors and other parts with safety to themselves and the aeroplane

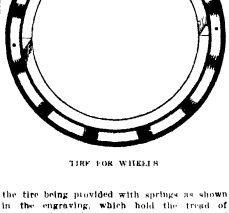
REVOLVING PLANE.—J HAYDEN, Box 558, Salt Lake City, Utah This invention has reference to revolving planes for flying machines, to take the place of the stationary planes now used therein An object is the provision of a device which will be simple in construction, inexpensive to manufacture, strong, durable easily controlled and having a great supporting efficiency

Pertaining to Recreation.

CUE RACK.—M R BASS and W A ALEXANDER, 2 Oneida Street Boston Mass This rack is so constructed as to provide for imparting longitudinal compression to the cue while in the rack, for impelling the tips of the cues, and at the same time to so support the cues while under the compression action as to prevent lateral movement of the cues The rack can safely hold the cues when in seated therein, and prevent their withdrawal without the consent of the user or owner of the cues

GAME APPARATUS.—J V B RAPP, 507 Fifth Avenue, Brooklyn New York, N Y In this game use is made of a field having the home plate and bases marked thereon indications of plays adjacent the home plate and bases and a revolvable spinner or pointer pivoted to the center of the field and having four points adapted to indicate on the said indications on the home plate and bases

REEL.—H HALL Paonia Colo This invention relates generally to reels adapted to be applied to fishing rods such as is the subject matter of the patent No 977,742 formerly granted to Mr Hall and more particularly it relates to a reel having gearing therein cooperating with the reel proper and the handle, wherein successive turning of the handle in opposite directions will cause the line to wind up in the reel



Railways and Their Accessories.

METALLIC RAILWAY TIE.—J N KEMMERER, Logansport Clinton Co Pa In the present patent the object of the inventor is to provide a metallic tie which shall combine maximum strength rigidity, and lightness and may be manufactured at a low cost may be easily placed in and removed from the roadbed, and will support rails firmly without danger of moving endwise

Pertaining to Vehicles.

RESILIENT WHEEL.—F MORRIS 2912 Farnam Street Omaha, Neb This improvement pertains to resilient which wheels or combined cushion and pneumatic tire wheels An object of the invention is to provide a wheel which will have the same resiliency as an ordinary pneumatic tire wheel, but which is so constructed that the pneumatic tire does not come in contact with the ground and is thereby protected against puncture

TIRE FOR WHEELS.—FRANK GATTACHER, Route 2 Canton Minn In this patent the invention has reference to tires for wheels, and it has for its object the production of a tire which may be readily adjusted to a wheel,

TIRE FOR WHEELS

the tire being provided with springs as shown in the engraving, which hold the tread of the tire yieldingly extended from the felly of the wheel The tire is made in sections which are bolted together around the felly of the wheel The number of springs in each tire may be regulated with reference to the use to which the tire is to be put The illustration pictures the tire in longitudinal section

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each Please state the name of the patentee, title of the invention, and date of this paper

LEGAL NOTICES

OVER 65 YEARS' EXPERIENCE

PATENTS

TRADE MARKS
DESIGNS
COPYRIGHTS &c.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, on 625 F Street, Washington, D.C., in regard to securing valid patent protection for their Inventions, Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Our's is the Oldest agency for securing patents; it was established over sixty-five years ago.

Valuable Books

The Scientific American Cyclopedia of Formulas

Edited by ALBERT A. HOPKINS. Octavo, 1077 pages. 15,000 Recipes. Cloth, $5.00; half morocco, $6.50

¶ This valuable work is a careful compilation of about 15,000 selected formulas, covering nearly every branch of the useful arts and industries. Never before has such a large collection of valuable formulas, useful to everyone, been offered to the public. Those engaged in any branch of industry will probably find in the volume much that is of practical use in their respective callings. Those in search of salable articles which can be manufactured on a small scale, will find hundreds of most excellent suggestions. It should have a place in every laboratory, factory and home.

Handy Man's Workshop and Laboratory

Compiled and edited by A. RUSSELL BOND. 12mo., 467 pages, 370 illustrations. Price, $2.00.

¶ This is a compendium of hundreds of valuable suggestions and ingenious ideas for the mechanic and those mechanically inclined, and tells how all kinds of jobs can be done with home-made tools and appliances. The suggestions are practical, and the solutions to which they refer are of frequent occurrence. It may be regarded as the best collection of ideas of resourceful men published, and appeals to all those who find use for tools either in the home or workshop. The book is fully illustrated, in most cases with working drawings, which show clearly how the work is done

Concrete Pottery and Garden Furniture

By RALPH C DAVISON 16mo., 196 pages, 140 illustrations. Price, $1.50

¶ The book describes in detail in a most practical manner the various methods of casting concrete for ornamental and useful purposes. It tells how to make all kinds of concrete bases, ornamental flower pots, concrete pedestals, concrete benches, concrete fences, etc. Full practical instructions are given for constructing and finishing the different kinds of molds, making the wire forms or frames, selecting and mixing the ingredients, covering the wire frames, modeling the covered plastic into form, and casting and finishing the various objects. With the information given in this book, any handy man or amateur can make many useful and ornamental objects to consist for the adornment of the home or garden. The information on color work alone is worth many times the cost of the book

The Design and Construction of Induction Coils

By A. FREDERICK COLLINS. Octavo, 295 pages, 159 illustrations. Price, $3.00

¶ The work goes in minute details full practical directions for making eight different sizes of coils, varying from a small one giving a spark-inch long to a large one giving twelve-inch sparks. The dimensions of each and every part down to the smallest screw are given, and the directions are written in language easily comprehended. Much of the matter in the book has never before been published as, for instance, the vacuum drying and impregnating processes, the making of adjustable mica condensers, the construction of interlocking reversing switches, the set of complete wiring diagrams, etc. The illustrations have all been made from original drawings, which were made especially for this work.

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12569) G. W. G. says: In a recent issue I saw an article referring to a discussion in the English papers of the meaning of the word "anticyclone." Now, it is an interesting fact to which I would call your attention that the word "cyclone" is used by different people to denote each of the three different kinds of atmospheric whirls, which are distinguished absolutely from one another by meteorologists. In the newspaper vernacular it means a tornado, in French, and by implication the other Romanic countries, it means a hurricane or typhoon, with its proper meaning, according to our American meteorologists, is a broad flat whirl, known more familiarly as a "low." This is designated in French science by the term *Bourrasque*, which popularly connotes merely a storm. Will you not take this matter up, and inform your readers where and by whom the word "cyclone" was originated, and what it originally signified, and how it came to be appropriated to mean three different things. This would make more clear the true and proper significance of the word, as well as, naturally, that of the word "anticyclone," which appears to be used everywhere in its proper significance, for the obvious reason that there is, and can be no such thing as antihurricane or an antityphoon. The word "cyclone" was invented by Henry Piddington, of Calcutta, one of the founders of the modern theory of storms, and first appeared in his well-known Sailor's Horn Book, published in 1848. It was irregularly formed from the Greek word for circle, and was applied by its author to "all circular or highly curved winds . . . without any relation to the *strength* of the wind." Among the winds coming under this generic designation he enumerates hurricanes typhoons, whirlwinds, African tornadoes, simoons, and with a note of interrogation—"some gales of high latitudes." Under the term "whirlwinds" he would doubtless have included what is now called in America a "tornado"—and popularly a "cyclone"—the African tornado being a kind of the second variety. If Piddington were writing to day, he would hardly include the latter among the "cyclones." While, with advancing knowledge of the mechanics of the atmosphere, the application of this word has varied from one general notion of meteorologists to the next current usage in regard to it is nearly uniform in all languages. The "cyclone" of Hann's "Lehrbuch der Meteorologie" (even "Zyklone" by most other Germans) is identical with the "cyclone" of English and American meteorologists, while if our correspondent will consult Hildebrandson and Teisserenc de Bort's "Traité Atlas Général de dynamic meteorology, "Les bases de la météorologie dynamique," he will find that "cyclone" has the same application in French. Modern scientific usage recognizes only the two somewhat different forms of atmospheric whirl, viz., tropical (properly "intertropical") and extra-tropical cyclones, but not to the relatively small and local whirls known as spouts (waterspouts and landspouts—the latter including tornadoes), which are believed to originate in the upper atmosphere, or to the small dust-whirls and the like, due to local convection just above the ground. It must be admitted, however, that many meteorologists are so far influenced by the popular identification of cyclones with violent storms that they avoid the use of this word in the study of the cyclonic wind-systems of middle latitudes, which are not necessarily stormy, *preferring to refer* to those systems as "depressions," "barometric minima," "lows," etc. The same writers freely apply the word "cyclone" to the moving low-pressure systems within the tropics, where such disturbances always assume the character of storms, and are usually so violent as to deserve their alternative name "hurricane." Thus J. Algué's standard work on typhoons is entitled "The Cyclones of the Far East." *The fact that tropical cyclones are always storms—and usually violent storms—probably explains how the word "cyclone" came to be identified, in the popular mind, with a severe wind-storm.* This particular class of cyclones having been the subject of a great amount of practical discussion addressed to mariners, the term probably passed by way of the nautical vocabulary into the vocabulary of everyday life. Popular usage in this country is so nearly unanimous in identifying the cyclone with the tornado that lexicographers have been forced to accord a measure of recognition to this application of the word "cyclone," and it has even received the approval of the law courts. (See an interesting decision of the United States Circuit Court of Appeals reported in the *Monthly Weather Review*, June, 1907, p. 280 fg.) The word "bourrasque" has, as our correspondent states, been applied in French scientific literature to ordinary cyclonic disturbances, but is now obsolescent in this sense, and was never the *usual* term. A "bourrasque" is properly a violent and transient wind, especially a squall. This term belongs to the family of words—including "bora," "burran," etc.—derived from the Greek "boreas"—the blustering north wind blowing down from the mountains.

(12570) E. Q. K. writes: I wish you would explain the discrepancy between theory and observed facts which I have noticed in regard to the vernal and autumnal equinoxes, the period when the days and nights are equal in length. The dates are about the 21st or 22nd of March and September, according to the astronomers, yet the almanacs report a considerably longer day than night on those dates. Are the almanacs wrong, or do they give times of *apparent* sunrise and sunset, and are there reasons why the apparent time is not the real time of these occurrences?

I take the following from the *World* almanac for 1910:

	Sun rises	Sun sets	MARCH.
18th	6.0	6:9	(day and night equal on 18th)
19th	6:7	6:10	(day exceeds night by 3 minutes)
20th	6:5	6:11	(day exceeds night by 6 minutes)
21st	6:3	6:12	(day exceeds night by 9 minutes)
22nd	6.2	6:14	(day exceeds night by 12 minutes)

This would seem to make the 18th the date of the vernal equinox instead of the 21st.

	Sun rises	Sun sets	SEPTEMBER
21st	5 45	6 1	(day exceeds night by 16 minutes)
22nd	5:46	6 0	(day exceeds night by 14 minutes).
23rd	5:47	5.58	(day exceeds night by 11 minutes)
24th	5:48	5 56	(day exceeds night by 8 minutes)
25th	5.50	5.55	(day exceeds night by 5 minutes)
26th	5:51	5:53	(day exceeds night by 2 minutes)
27th	5.52	5.51	(night exceeds day by 1 minute)

Here the autumnal equinox appears to come somewhere between the 26th and 27th of September, while the 21st and 22nd show a large excess of daytime. A The times of sunrise and sunset as given in the almanacs are those at which the upper edge of the sun appears or disappears at the true horizon. As the sun is half a degree in diameter, and in our latitude goes down obliquely, this takes place 1½ minutes earlier at sunrise, and later at sunset, than the moment when the sun's center is on the horizon. This alone would make the day three minutes longer than the night when the sun is at the equinox. To this must be added the effect of atmospheric refraction, which raises the sun, when near the horizon, by half a degree—his whole diameter. This makes sunrise three minutes earlier and sunset three minutes later than otherwise would be the case. The combined effect of these two causes makes the day nine minutes longer than the night on March 21st and September 21st.

(12571) J. E. L. asks: Could you answer the following question to set some minds at rest? In playing baseball with the baseball series just past. You need not be surprised to hear from such a far western country and from people who seem to be so much interested in the American national game. Mostly all of us come from there. The question is. Would a *slow* ball met squarely in the face by a *bat*, rebound farther back than the same ball, being swift, met by the same bat with the same *force* behind? *If* it is possible to give some reasons to explain the natural result, it would set many minds at rest. A *fifty-in* a ball and bat of regulation size and a certain amount of energy between the ball and the bat, the ball will go to a certain distance with a certain velocity. It does not seem to us to make any difference whether the ball or the bat has the energy in equal or unequal portions, if the total energy is the same. That is, if the ball is at rest and is struck with a whole force, it will go with the same speed and to the same distance as if the bat were at rest and the ball struck it with this force, or if bat and ball are both in motion and come together when each has half of this force. In each case the ball will have the same force after rebound. The fact is that such a condition is not realized in an actual game. The batter sees the ball coming swiftly and puts in more force than if the ball were thrown slowly, and this is done instinctively. He must put more force into the bat, so that it may have the velocity necessary to find the swift ball before it gets past him. Balls are pitched swiftly, since there is more chance that a swift ball will be missed, and go to the catcher. The specific question which you propose can now be intelligently answered. The swift ball rebounds from the bat farther than a slow one can if the bat has the same force in the two instances, because the rebound is the sum of the force of the ball and of the bat. The rebound is due to the entire

"Inventors and Inventions"

A NEW BOOK JUST PUBLISHED BY MUNN & CO., 361 BROADWAY, NEW YORK. HANDSOMELY BOUND, 41 X 10½ INS. INTERESTING TO EVERY INVENTOR OR PROSPECTIVE INVENTOR. PROFUSELY ILLUSTRATED. CLOTH BOUND, 12,000 TECHNICAL TREATS AUTHORITATIVELY IN A CLEAR, POPULAR AND ENTERTAINING STYLE THE FOLLOWING SUBJECTS:

How to Invent. Rewards of New Inventions. Methods in a New Invention. Advice to Inventors. The Genius of Invention. Pictures of Famous Inventors. Various Ways Employed to Cheat and Rob Inventors. Present Available Means of Protecting an Invention. Treatment the World accords to Them, and Other Important Subjects.

Modern Foundry and Machine Shop Plant

FOR SALE
IN PROVIDENCE, R. I.

Ideally situated on the water front at the head of the harbor, with excellent deep water dock.

Modern Brick Foundry

with complete and strictly up-to-date equipment. All ready for business.
Foundry and connecting buildings cover approximately 18,000 square feet.

Machine Shop Division

contains complete power and lighting plant, electric and hand cranes. Besides machine shop are patterns and blacksmith shop, drafting room, offices, several small buildings. Well adapted for automobile or light textile business. Ample land for further improvements.
Write for price and descriptive circular to

HENRY W. COOKE CO.
18 Westminster St. Providence, R. I.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

AUTOMOBILES.

A NEW WHITE STEAMER. Model O-O, complete with top. Will be sold at a very reasonable price. Address A. A. Hopkins, 361 Broadway, New York City.

BUSINESS OPPORTUNITIES

TRAVELLING SALESMAN with 20 years' experience in this country good references, wishes to represent in Italy first class American firms. For further particulars address, Italy, Box 773, New York City

A STRONG, old established, manufacturing company in a national selling organization, wants to add a new line of building material or construction specialty to manufacture and sell. Address P. O. Box 94, New York.

FREE SAMPLE zone with the first letter. Something that every firm wants it. Orders from $1.00 to $100.00. Nice pleasant business in this section. Big profits. Write for free sample. Metallic Mfg. Co., 48 N. Clark, Chicago.

GOLD DREDGING MINES rich in Cyaniding. Mining Engineer wishes partner, will give liberal investments, big profits. Address "Mines" care Box 773, New York only. 8 Pinkelman, 32 West 25th street, New York.

A HIGH CLASS INVESTMENT.—Salesman wanted in every City and Town. Best of the kind—Entire River Exclusive territory. Contract will be entered into with men who show evidence as to character, ability, record, etc. (Investment, Insurance and Real Estate men need not apply.) This is a splendid opportunity for trusty business-getters to represent a large Eastern Corporation which is doing a safe, profitable and attractive investment, backed by the strongest references of the financial organizations standing. Address Manager, 507 Metropolitan Bank Building, Washington, D. C.

FOR SALE.

FOR SALE.—Spring Bolt Lock. Patented Oct. 3rd, 1911 in Sunday Scientific American. Said Lock is and is constructed that a wax impression thereof, for the purpose of making a key, would practically be impossible. R. Russell, 320 N. Broadway, St. Louis, Mo.

PATENTS FOR SALE

FOR SALE. Recently patented Railway-Track Construction. Patent No. 1,004,202. Any reasonable offer will be considered. For further information, address Ramapo Takaos, Box 187, Morris, N. J.

REAL ESTATE.

TEXAS INVESTMENTS.—Buy farm orchard garden lands near Houston, the principal and most populous city in the southwest, where values are going up all the time on account of growth in population. Easy terms if desired. Single crop pays for land; investigate. Address R. C. Richardson, 301 Dunn Bldg., Houston, Tex.

WANTED.

WANTED.—A man or woman to act as our information agent in their spare time. No canvassing necessary. Salary to $25 per month. Experience unnecessary. For particulars, Sales Association, 29 Association Bldg., Indianapolis, Indiana.

MISCELLANEOUS.

SUPTUBA. A new patented suction pump in place of the ordinary. Can be operated successfully and inexpensively by landing surgeons. For particulars, address J. L. Rowe, R. D. 1, Tiffin, Ohio.

DIPLANE TO WIN GOULD PRIZE. Cannot fall. Solid quality, low ground travel engine. Will climb 1,000 feet in 1 minute. Will fly for 2 hours. Will win Gould Prize. Kansas City, Mo.

INQUIRY COLUMN

Inquiry No. 9264.—Wanted, the names and addresses of manufacturers of hand tools and gun locks. Also of gun locks for repairing and replacing on guns.

Inquiry No. 9265.—Wanted, the name and address of a manufacturer of small electric motors.

Either type, as above, silk, 50 cents, lisle, 25 cents. At stores everywhere. Sample pair sent postpaid on receipt of price.

Boston Garter

"For thirty years the standard—from first to last the best." Holds up the half hose as smooth as your skin. Guaranteed against imperfections. Look for the moulded rubber button and the trade marks on the loop.

GEORGE FROST CO., MAKERS, BOSTON

A Permanent Edge

You can keep your razor constantly keen, so it will give you a close, comfortable shave every day, if you use our

New Torrey Honing Strop

You don't need any experience or any special skill—the new strop will do it all. The sharpening side is prepared with our newly discovered sharpening dressing. This is our secret and no other strop in the world has it. That is why the New Torrey Strop keeps your razor in so much better condition than any other strop. If your dealer cannot show you the New Torrey Honing Strop—write us for full information. Booklet, all about shaving, sent free on request.

Prices 50c, 75c, $1.00, $1.25, $1.50, $2.00 and $2.50

Get a Torrey Razor—the Best Made.

Every dealer who is not now selling the New Torrey Honing Strop should write at once for our special proposition.

J. R. TORREY CO., Dept. G, Worcester, Mass.

THE EDISON Concrete House

How is it constructed, how much it will cost, is it practical from an architectural and engineering standpoint? These and other important questions relating to the structure are discussed in a good, thorough, illustrated article published in *Scientific American Supplement 1605*. Price 10 cents by mail. Repairing Watches

WE WILL HELP YOU START IN BUSINESS

This is not a correspondence school. It is a big watch factory and repair shop where we give you actual practice. You can step at once into a good position. You can open a shop of your own and make your fortune. WE GIVE INSTRUCTIONS FREE BECAUSE WE WANT YOU TO REPRESENT US.

We mean just what we say. We will furnish you, free of cost, text-books, clear, simple illustrated lessons and photo prints showing the exact way to do any kind of watch repairing. Our regular charges will do the following, free for you until you learn how—so as to take the profits yourself.

IF YOU WANT BUSINESS

We will look you in the face. We will start you right. You will have the benefit of our experience, knowledge and reputation. We will supply you with materials at wholesale prices, and help you in every way to make money. You can commence repairing watches in your spare time, without losing your present position. Our system of instruction by mail is so complete and thorough that failure is impossible. Write for our free book and full particulars.

force at the point of rebound, that of the bat and the ball. The force of the bat is the same both times, but the slow ball has less force than the swift ball. Hence the rebound of the slow ball is with less force than that of the swift ball. The resulting velocity is less, and the distance to which it flies is less

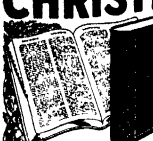
The Current Supplement

IN the current issue of our SUPPLEMENT, No 1874, Marconi, the pioneer of the art of radio-telegraphy, concludes his account of its development.—The largest electric generator in the world has recently been installed by the New York Edison Company on the East River, New York city. An illustrated account of the starting up of this giant turbine and generator furnishes the frontispiece of this issue.—An automatic device for preventing the unduly sudden rise of current on closing the switch of a motor, presenting an important advance in the design of this type of apparatus, is described and illustrated.—The handling of materials, both raw and finished, in manufacturing plants, is a very important problem at all times. Some interesting examples of what has recently been done along these lines are described and illustrated.—A very interesting review of the speed records attained by various methods of locomotion, both on the earth's surface and above it, is reproduced from Nature, in which Prof Hele-Shaw's address before the Royal Institution was originally published.—Mr J J Ide, who has been contributing some very excellent articles on various types of flying machines, this week tells us of the Deperdussin monoplane.—An article containing much useful information on wire and wire ropes in aeroplane construction is reproduced from the *Electrician and Mechanic*.—Our astronomical readers will take interest in an article on the orbit of Beta Persei.—Other subjects tell of the automatic regulation of boiler water, the power derived from ocean waves, and the deceptions to which our senses are subject

NEW BOOKS, ETC.

PRACTICAL APPLIED ELECTRICITY A Book in Plain English for the Practical Man Theory, Practical Applications, and Examples By David Penn Morton, B.S., E.E. Chicago. The Reilly & Britton Company, 1911 12mo, 428 pp, illustrated Price, $2 net; postage 12 cents extra

The manual is addressed to those who wish to acquire a general yet practical knowledge of electricity without going so far as to take a complete course in electrical engineering Only the simplest mathematics are used and an effort is made to weld indissolubly the fundamental principles and practical applications. The arrangement and treatment follow closely the course given in the evening classes of the Armour Institute of Technology, and the manual might be used as a text-book in High Schools and Manual Training Schools. A "Worker Edition" is also issued, in flexible leather with protecting flap, inside pocket, and memoranda pages, at an advance of fifty cents in price over the regular edition.



NATIONAL PROBLEMS AFFECTING THE LUMBER INDUSTRY Tacoma, Washington National Lumber Manufacturers' Association, 1911. 8vo 278 pp Price $1

The annual conventions of the National Lumber Manufacturers' Association are always productive of many timely and important papers and addresses The full proceedings of the ninth annual meeting are given by the present in hand. There are opinions on Canadian reciprocity, able reviews of the business situation, and remarks on co-operation with the leaders of the conservation movement The more important papers deal with such subjects as workmen's compensation, the principles of efficiency, currency reform, the Panama Canal in its relation to the lumber industry of the Pacific Coast, substitutes for wood, and the railroads and the lumber industry Some opposition develops toward the Canadian reciprocity bill, and the measure is condemned as agreeing with no economic theory and as being particularly threatening to the prosperity of the lumber industry of the United States.

HANDICRAFTS IN THE HOME. By Mabel Tuke Priestman. New York: A. C. McClurg & Co, 1911. 8vo; 238 pp. Price, $1 net.

The handicrafts dealt with have been selected with a view to the practicability of their pursuit within the home. The work is written out of the fullness of expert knowledge for the benefit of those who, while desirous of taking up some creative occupation in their leisure hours, either for pleasure or for profit, yet lack the means or the opportunity of placing themselves under personal tuition. No expensive outfits are required for any of the pursuits treated of, and the instructions presuppose no technical knowledge on the part of the reader.

The GREATEST **CHRISTMAS GIFT OFFER EVER MADE $3.50**

WE HAVE the largest printing and book-binding plant in America. It must be kept busy the year 'round, whether times are slack or good. For that reason we have arranged to publish this greatest encyclopedia of modern times and sell it at manufacturer's cost. Two years of tireless research by world-prominent educators have made this wonderful encyclopedia so complete that it gives instant reply to the thousands of questions arising in our daily experience. Printed in large type—easy to read—on opaque India paper—improved methods of binding, bring the two volumes into a thickness of 14 inches each. Contains 2,700 pages, size 8½ x 6¾. Bound in flexible cloth or morocco, lays flat when open. A condensed rival to the best and most expensive encyclopedias published.

Keep them for ready reference—at home—at your office—or any place where you are likely to want practical authoritative information right away. No digging through scores of volumes to get the gist of a subject. Whether Business, Art, Religion, Science or any one of 6,000 subjects—you will find it in these two books—boiled down—brought to a focus—sharpened up so that you can see the point without unnecessary reading. Completely thumb indexed for instantaneous reference. The whole range of knowledge is summed up in these two convenient, flexible cover books.

READ THIS EXPERIMENTAL OFFER

Thousands of these sets have been sold at $6.25 and were well worth it. If we can sell them by the tens of thousands at $3.50, we will do it to keep our plant busy the year 'round. This will return us cost of making and give you the benefit of buying without middleman's profit that the $3.50 offer is only experimental and the price will go up at once unless large sales come back quickly from this advertisement, so order now—this offer may not appear again. Two massive, beautiful encyclopedias, 2 volumes, flexible cloth bound, and dictionary, 30,000 words, same in the large edition, bound in genuine American morocco, gold embossed, $4.00 prepaid. Send no money. If not delighted—send for it and get your money back. If you are satisfied after examination of the thousands to get in on this experimental price of $3.50 you are lucky—by next mail. Be one

HOW TO MAKE A 100-MILE WIRELESS TELEGRAPH OUTFIT

In the following *Scientific American Supplements*, the well-known wireless telegraph expert, Mr A Frederick Collins, describes clearly and simply, without the aid of mathematics the construction of a 100-mile wireless telegraph outfit Complete drawings accompany his descriptions

1605—The design and construction of a 100-mile wireless telegraph set
1622—The location and erection of a 100-mile wireless telegraph station
1623—The installation and adjustment of a 100-mile wireless telegraph station is fully explained
1624—The adjustment and tuning of a 100-mile wireless telegraph outfit
1625—The theory and action of a 100-mile wireless telegraph outfit
1626—The management and operation of ship and shore stations is clearly set forth

These articles constitute a splendid treatise on the construction, operation and theory of wireless telegraph instruments. The complete set will be mailed to any address for 60 cents Single numbers will be mailed for 10 cents Send for a 1910 Supplement catalogue free to any address Order from your newsdealer, or from

Three Unusual Books

THE CHANGING CHINESE

By Edward Alsworth Ross, PH.D., LL.D.

Professor of Sociology in the University of Wisconsin, and author of "Sin and Society," "Social Control," etc.

The first presentment, by a sociologist of adequate modern equipment, of the conflict of Oriental and Western cultures in China.

An interpretation of Chinese society, by the method of first-hand observation. Professor Ross declares, and gives his reasons, that the race mind of the Chinese is not appreciably different from our own

A vivid and fascinating picturing of Chinese life and customs, and so a book of extraordinary interest for the general reader as well as for the student. Over 100 illustrations from photographs which really illustrate, and reproductions of some interesting Chinese cartoons

8vo, 350 pages. Price, $2.40 net, postage 18 cents.

THE SECOND BOYS' BOOK OF MODEL AEROPLANES

By FRANCIS ARNOLD COLLINS

The book of books for every lad, and every grown-up too, who has been caught in the fascination of model aeroplane experimentation, covering up to date the science and sport of model aeroplane building and flying, both in this country and abroad This, and the author's earlier book, "The Boys' Book of Model Aeroplanes," will open a new world to boys

The illustrations are from interesting photographs and helpful working drawings of over one hundred new models.

Price, $1 20 net, postage 11 cents

STORIES OF USEFUL INVENTIONS

By S. E FORMAN

Author of A History of the United States, etc

Sixteen "true" stories, stories of human progress as shown in man's making of the match, the stove, and other inventions which are most useful to man in his daily life, told to stir and hold the interest of the young reader This is the first time these chapters in the history of human civilization have been brought together in a book

The Heavens in December, 1911

(Concluded from page 504.)

and very bright. He is south of the Pleiades at the beginning of the month, and moves slowly westward Telescopically he shows a disk about 19 seconds in diameter, upon which much detail may be seen under favorable atmospheric conditions By the end of the month his distance has increased from 49 to 64 millions of miles, and he appears correspondingly fainter and smaller.

Jupiter is morning star in Scorpio, rising about 5.30 A. M. in the middle of the month

Saturn is in Aries, well past opposition, but still conspicuous in the evening sky

Uranus is in Capricornus, too near the Sun to be observed. Neptune is in Gemini, approaching opposition, but too faint to be seen without a telescope.

The Moon is full at 10 P. M on the 5th, in her last quarter at 1 P M. on the 12th, new at 10 A. M on the 20th, and in her first quarter at 2 P. M. on the 28th She is nearest the Earth on December 6th, and farthest away on December 21st

In her circuit of the skies she passes near Saturn on the night of the 3rd, Mars at 11 P M. on the 4th, Neptune on the 8th, Venus on the 16th, Jupiter on the 18th, Mercury on the 21st, Uranus on the 22nd, Saturn again on the 31st, and Mars once more about three hours after the new year begins

The two conjunctions with Mars are close As seen from Washington, the planet is about 15 minutes south of the Moon's limb on the 4th, and about 20 minutes north on New Year's Eve

Princeton University Observatory

The Manufacture of Yeast

(Concluded from page 496.)

passed between cylindrical rollers which bruise it without grinding it to powder. The product is now mixed with water, whereby the so-called must or saccharine liquid for fermentation is obtained. The preparation of this liquor is carried out in double-bottomed macerating tubs, heated by steam and provided with mechanical agitators The materials fed into these tubs consist of a mixture in about equal parts of flour and barley, the diastase in the malted barley being sufficient to turn into sugar not only the starch contained in the grain itself, but a further quantity, furnished in the form of untreated starch It is, of course, an economy to malt only a portion of the grain and make it do duty for saccharifying both its own starch and a further quantity upon which no malting operation has been performed As soon as the saccharification is complete, the product, in form of a doughy slush, is introduced into double-bottomed copper coolers, in which it is cooled down to 20 deg Cent From the refrigerator the must is distributed to a number of tubs of 220,000 gallons each, arranged in a special room, whose temperature is maintained constant through summer and winter, as this is an indispensable factor for the successful operation of the process The tubs are then inoculated with a quantity of yeast carefully prepared. The temperature of the must reaches 25 deg Cent at the start, and must not be allowed to exceed 30 degrees. It is important to rigorously observe these limits of temperature and to be scrupulously careful in the preparation of the grain, in maintaining the right proportions for the mixture, and in insuring absolute cleanliness of every part of the plant From time to time, until the fermentation is completed, the yeast is gathered from the surface of the liquid in the tub. The yeast is then sifted in order to separate it from the malt and the mucilaginous material admixed with it, whereupon it is passed through a filter press which delivers it in the shape of slabs or cakes. Finally, the yeast is stamped in a briquetting press and made up in parcels of one pound, two pounds, and one-half pound, which are carefully packed in double wrappers for delivery to bakers and pastry cooks

The must, on the other hand, after the fermentation is completed, is carried off to reservoirs in the cellar, whence it is pumped to the stills. By a series of suc-

cessive distillations, the alcohol is driven off, and collected for marketing in the form of "rectified spirits." The residue from the distillation is drawn off to a large tank provided with a stirrer, and is then distributed, while still warm, to be used for cattle food, or it may be collected in large wooden reservoirs and shipped in bulk or in casks. This malt residue contains most of the original nitrogen of the grain and a certain quantity of dextrine and unconverted starch, and forms one of the most nourishing fodders for cattle Another by-product of the industry is the carbon dioxide which is formed in the fermentation process This may be liquefied and placed on the market in steel cylinders

Chinese Wood-oil Tree

To the Editor of SCIENTIFIC AMERICAN.

In your issue of September 23rd, at page 275, you express the opinion that the Tung, or Chinese wood-oil tree, "might flourish in warmer parts of the United States"

My purpose in writing this is to inform you that it does flourish in Louisiana as far north as Red River in the central part of the State of Louisiana Here at Abbeville, in the southwestern portion of the State, near the Gulf of Mexico, I have several trees measuring nine inches in circumference and over twenty feet high, which mature their fruit and are only four years old It is of erect habit, handsome appearance its branches are easily controlled, and I should consider it an ideal ornamental tree for cities where the crowded conditions of tall walls and buildings leave little room for the ordinary trees It flowers early in the spring, and its blossoms are very beautiful and quite fragrant.

Abbeville, La C J EDWARDS

Nitrogen and the Soil

To the Editor of SCIENTIFIC AMERICAN

It has just now come to our notice that in the edition of the SCIENTIFIC AMERICAN published August 19th, 1911, there was a communication from Dr J G Lipman of the New Jersey Agricultural Experiment Station, in which he claims that the priority of discovery that "a legume growing with a non-legume causes the latter to contain a higher nitrogen content than if the non-legume were grown alone" rests with him, or as he expresses it, with the New Jersey Experiment Station If his objection is based on the contention that this fact was announced by him before it was by the undersigned, his position is untenable, as we published conclusive evidence of this in the *Journal of Industrial and Engineering Chemistry*, July, 1910, and also presented it at the Omaha meeting of the American Society of Agronomy December 7th and 8th, 1909 The latest of these was several months previous to the appearance of the article in the *Journal of Agricultural Science*, Vol III, Part III, and the note in the Report of the Office of Experiment Stations for 1909 in which Dr Lipman claims to have made a similar announcement, both of which publications appeared in October, 1910

Our article on "Availability of Soil Nitrogen in Relation to the Basicity of the Soil and to the Growth of Legumes" contained a detailed description of our investigation, including statements of analysis of the non-legumes grown with and without legumes This article was received by the editor of the *Journal of Industrial and Engineering Chemistry* on April 21st, 1910, and appeared in July of that year. The articles published by Dr Lipman in which he claims to have made a similar announcement were the follow ing: "A Method for the Study of Soil Fertility Problems," which appeared in the *Journal of Agricultural Science*, Vol III, Part III, and was received at the Cornell University Library on October 12th, 1910, and a brief note in the Annual Report of the Office of Experiment Stations for 1909, which publication bears the date of issue October 10th, 1910, on its cover.

It will be noticed that both of these publications appeared several months after our article in the July number of the *Journal of Industrial and Engineering Chemistry*. In neither of Dr. Lipman's publications are any figures given to show that the fact had been demonstrated, that legumes may increase the nitrogen content of non-legumes growing with them

We have a high respect for Dr Lipman's work, and have no doubt that he had come to the same conclusion that we had reached as the result of his own work, but we feel that it was only proper that we should make this explanation to show that we announced the fact before Dr Lipman did, and furthermore published our results in detail We regret that a public explanation is necessary, but the communication in the August 19th number of this journal requires this It is altogether probable that Dr Lipman failed to see our article in the *Journal of Industrial and Engineering Chemistry* before he wrote his communication

The Naval Review at New York

To the Editor of SCIENTIFIC AMERICAN

The fleet that was reviewed by President Taft on the second of November was the most formidable ever assembled in American waters, exceeding by a wide margin the allied fleet that participated in the Hudson Fulton celebration two years ago

Comparing the Atlantic fleet of that time with the present, we find that the strength in pre-dreadnought vessels is about the same while the addition of the six all-big gun ships more than offset the foreign vessels that were in the Hudson at that time

The English flagship "Inflexible" would be easily outfought by the "Delaware," while the three remaining cruisers would be mere stationary targets for the powerful 12-inch gun batteries of the "Utah" and "South Carolina" Admiral Von Roesters German vessels would find the lone "North Dakota" more than a match for them The ill-fated "Liberté" and her sister ships "Justice" and "Verité," carrying four 12-inch guns each could make but a feeble fight against the combined attack of the "Florida" and "Michigan." Unaided by the cruisers, the veterans "Indiana" and Massachusetts" could dispose of the remaining foreign vessels with a few effective broadsides.

Upbuilding Our Merchant Marine

To the Editor of SCIENTIFIC AMERICAN

Since writing you within the past few weeks the writer has eagerly scrutinized your correspondence column, hoping to find some manifestations of interest from your readers on the revival of the American merchant marine If all the great journals in this broad land would do as much as you have already done to enlighten the public on this subject, the great mass of the people, in the interior especially, would be much better informed in regard to the actual status of our shipping interests Such information would enable and incline them to send more statesmen and fewer demagogues to Congress, and would result in the enactment of such a shipping law as would stimulate our foreign commercial interests, and at least lay the foundation for such a merchant marine as would command the respect of the nations of the earth.

The situation calls for immediate action, and the friends of American shipping interests should endeavor, if possible, to accomplish something at the approaching session of Congress

THE BEST Christmas Present for $1.75

What other Christmas Present costs so little and means so much?

Fifty-two Crowded Numbers

The Youth's Companion for All the Family

ON JANUARY 1, 1912, the subscription price of The Companion will be advanced to $2.00 a year. When subscribing for your family (at the present price, $1.75) why not include two or three of your friends who will enjoy The Companion during the 52 weeks of the coming year? Every number in 1912 will be filled with reading of the most entertaining and helpful kind. There will be nearly 250 complete stories—stories of wild Indian life, stories of life at sea; stories for men and women, for boys and girls; there will be articles by famous writers, among them Lieut.-General Baden-Powell, founder of the Boy Scouts; Sir Harry Johnston, the famous African traveler and hunter; Frank Bullen, British sailor and harpooner; Hudson Maxim, inventor of high explosives; General Charles King, Jacob Riis, Margaret Sangster, Governor Harmon of Ohio, and many others. Subscribe to-day and receive Free the issues containing the opening chapters of

THE CROSS AND THE DRAGON

By RALPH D. PAINE

A serial story of missionary devotion and heroism in the Chinese Boxer Rebellion. It relates the adventures of Jack Langworthy, son of a missionary, who, with two friends, rescued Barbara Ellsworth and her father from the beleaguered compound in which, with other missionaries, they had taken refuge. It is a story which will enlist every reader's interest and sympathy from the beginning.

All Remaining 1911 ISSUES FREE

IF YOU CUT OUT AND ENCLOSE THIS CHRISTMAS PRESENT COUPON (OR MENTION THIS PUBLICATION) WITH $1.75 FOR A NEW SUBSCRIPTION TO THE COMPANION FOR 1912, WE WILL SEND

1. **All the Issues for the fifty-two weeks of 1912.**
2. **All the Issues for the remaining weeks of 1911, including the Holiday Numbers.**
3. **The Companion's Picture Calendar for 1912, lithographed in ten colors and gold—an extra copy going to every one making a gift subscription.**

All for $1.75

Your last opportunity to get The Companion for $1.75. On January 1, 1912, the Subscription Price will be advanced to $2.00. Subscribe NOW—TO-DAY—and save 25 cents!

THE YOUTH'S COMPANION, BOSTON, MASSACHUSETTS

The United States Navy

Has Every Kind of Work For Ambitious Men

SUCCESSFUL applicants for Navy positions find work, not only as seamen, but as machinists, firemen, stenographers, bookkeepers, musicians, carpenters, blacksmiths, shipfitters, electricians, boilermakers, cooks, stewards, waiters, and others

This is why so many young men who have taken for granted that there was no kind of work in the Navy that they would like, have found, on investigation, more agreeable work and more variety of positions than in civil life

The United States Navy offers a life that is healthy, work that is pleasant; excellent opportunity for promotion, the incentive to save money, and the finest of chances to learn by study and travel And besides these things, companionship of ambitious men of good character

The Navy Department never urges men to enlist, only to investigate Navy opportunities It is worth the while of any man, 17 to 35 years of age, to look into the subject of taking four years' training in the Navy, or of making the Navy a life's work

Call at the nearest Navy Recruiting Station (we'll send address at your request) and ask all the questions you wish Or send for interesting free book, "The Making of a Man o'Warsman" Address

The Importance of the Command of the Sea

THE existing contest between Italy and Turkey, confined as it is to the sea and to the possession of Tripoli, has a double interest. It illustrates on the one hand the gradual yet perpetual process by which a higher civilization impinges upon a lower that is, upon one that is lower in ability, efficiency however in some instances it may have been higher in acquired material comfort, or even in literary and artistic achievement. This tendency can neither be regulated by law, nor brought to the bar of law without injury to the progress of the world toward better universal conditions to which end it is essential that the efficient supplant the inefficient. On the other hand this collision illustrates the importance of the command of the sea. This also it should be noted, has been incidental and determinative in the progress of the world. Through having this command Italy thus far has been able to localize the land fighting in Tripoli and probably can continue to do so, to the great relief of her own resources, and that of a watching and anxious Europe.

It is to this second consideration that I am here limited in my subject—"The Importance of the Command of the Seas" with a somewhat special reference to that importance as touching the United States. The United States in her turn, after having achieved national efficiency by the quenching of internal discord in a bitter and bloody contest, has found herself compelled inevitably into the same path of seeming aggression upon less efficient social and political communities, to bear her part of "the white man's burden" as it has been styled. For in essence this process is not one of *aggrandizement*, but of *responsibility*—responsibility not to law, which always lags behind conditions, but to moral obligation entailed by the particular circumstances of the moment of action.

This moral side of the question is not irrelevant to the military one of the importance of commanding the sea; for granting the end, the moral obligation—the means, if not themselves immoral follow as a matter of course. Of such means *command of the sea* is one. Napoleon said that *morale* dominates war, and it is correspondingly true that a sense of right power unites to reinforce the stability of national attitude and the steadfastness of national purpose. If we have been right morally step by step, in the forward march of the past few years, we are morally bound to sustain the position attained by measures which will provide the necessary means. Of these an adequate navy is among the first, probably in our case, the chief of all.

Here, as always, it is necessary to recur to experience—to the past—in order to comprehend the present and to project the future. Why do English innate political conceptions of popular representative government, of the balance of law and liberty prevail in North America from the Arctic Circle to the Gulf of Mexico, from the Atlantic to the Pacific? Because the command of the sea at the decisive era belonged to Great Britain. In India and Egypt administrative efficiency has taken the place of a welter of tyranny, feudal struggle, and bloodshed, achieving thereby the comparative welfare of the once harried populations. What underlies this administrative efficiency? The British navy, assuring in the first instance British control instead of French and thereafter communication with the home country, whence the local power without which administration everywhere is futile. What, at the moment the Monroe Doctrine was pro claimed, insured beyond peradventure the immunity from foreign oppression of the Spanish-American colonies in their struggle for independence? The command of the sea by Great Britain, backed by the feeble navy but imposing strategic situation of the United States, with her swarm of potential commerce-destroyers, which a decade before had harassed the trade of even the mistress of the seas.

Less conspicuously but no less truly, to what do Algiers and Tunis, and to what eventually will Morocco, owe redemption from conditions barely, if at all, above the barbarous? To the command of the sea by the nation which already has restored the former two to be fruitful members of the world community. That South Africa is now a united commonwealth, instead of two opposing communities, such as the North and South of our own country might have been, is due to the same cause, a local preponderance of force insured by sea power. It may safely be claimed that to the navy of the United States chiefly is owing the present Union, instead of the existence of two rival nations vying or trying to vie, with each other in *military preparations* like the nations of Europe. The four years' struggle of the Confederate States might not have ended in exhaustion, had it not been for the blockade, which shut in their cotton and shut out their supplies.

Contrast this impressive exhibit where the command of the sea has been operative, with the history and achievement of those great States which have not possessed it. Contrast Bosnia and Herzegovina for Austria Alsace and Lorraine for Germany, with the expansion of France, Great Britain Holland and with that which Spain once possessed now lost through an inefficiency, one of the first symptoms of which was the decay of her navy. The magnificent efficiency of the present German Empire strives now, against almost hopeless disadvantage, for the opportunity to exercise that efficiency outside its European limits. Opportunity was lost through the absence of naval force, in the past centuries, when the maritime countries were occupying and in accordance with their respective political aptitudes, were determining the future of immense tracts of the world. Much time must elapse before we shall know the inside history of the still unarranged dispute with France about Morocco, but there is reason to believe that the consciousness of the British navy at the back of France has been one of the large factors in the negotiations. At least it is apparent that *bitterness against Great Britain* has been even more marked than against France.

The lesson for the United States is plain. In the strategic position before mentioned, in remoteness from Europe, in the rivalries of European nations we still have a local and international advantage for preponderance in American waters, but it is not so great as to confer certainty without reasonable provision for *insuring command of the sea*. In the Pacific which is equally our coast line, and to which the future mostly looks, we have no similar advantage. Much as I dislike and reject the phrase "supremacy in the Pacific," it is true that we there have duties which in case of disputes will require the presence of naval force adequate to command. Duty to the mutual support of our two chief coasts dictates full control of the Panama Canal, which from the military standpoint is the key to any broadly planned system of preparation for national defence.

But obligation is no less on account of the Philippine Islands. Having assumed control of these under imperative circumstances we are bound in honor to support an undertaking, our fitness for which is attested by results. To them we are responsible for the maintenance of conditions under which material prosperity can advance, and their dissimilar and discordant inhabitants, reach a homogeneous civilization and political development which will enable them to govern themselves. To Cuba, though independent, we owe by specific guarantees the maintenance of a like internal security. These national and international functions can be discharged, certainly only by command of the sea. The Pacific the Atlantic, and the Caribbean with the great controlling stations, Porto Rico, Guantanamo, the Canal Zone, and Hawaii depend upon this command, the exponent of which is the navy, and in which ships and stations are interdependent factors. To place the conclusion concretely and succinctly, the question of command of the sea is one of annual increase of the navy. This question is not "naval," in the restricted sense of the word. It is one of national policy, national security, and national obligation.

A. T. Mahan
Rear Admiral, U. S. N.

For an Adequate Navy

IN common with all who believe in the ultimate triumph of the best in human nature, we look forward confidently to that enlightened era, in which the exercise of mutual consideration and simple common sense shall have rendered possible the abolition, in part if not in whole, of the world's vast armaments, and the substitution therefor of an international court of arbitration.

For those of us who have learned to look upon questions of international moment from the broadest possible standpoint, however, it is impossible to overlook the fact that the question of arbitration and partial or complete disarmament is intimately, nay essentially, bound up with our relation to that populous Oriental world—Mohammedan, Buddhistic, and Confucian—whose teeming millions are only now being quickened to a realization of the dignified position which, by every right of ancient civilization and their unquestioned mental equipment and physical resources, they seem entitled to fill in the future history of the world.

The awakening of the Orient *to a sense of its latent* powers—ushered in, as it was, by the stupendous drama of the Russian-Japanese war, and echoed in the present unrest in India and China, and the existing struggle between Christian and Mohammedan armies—may well give us pause and confirm in us the conviction, voiced by our President, the most distinguished advocate of international arbitration, that "until peaceful means of settling all international controversies are assured to the world, prudence and patriotism demand that the United States maintain a navy commensurate with its wealth and dignity."

The SCIENTIFIC AMERICAN, then, stands for an adequate navy, not for aggression, but as a reasonable insurance upon the national wealth of the United States, which at the last official estimate, in 1904, had reached the vast total of over one hundred and seven billions of dollars. In the absence of an army adequate for our defense, the protection of our lives and property becomes the duty of the navy, and last year we placed upon the population and wealth of the United States a naval insurance of one hundred and fifty-six million dollars—a very moderate rate of one and one-half per cent. In view of the fact that because of our geographical location we are free from the burden of such enormous armies as are maintained by contiguous European nations, "prudence and patriotism" demand that we carry additional naval insurance, by adding to our line of defense annually, the four capital ships which are deemed necessary by the Naval Board at Washington.

The SCIENTIFIC AMERICAN stands for an adequate navy, furthermore, because we believe there is no national institution in which the best traditions and finest characteristics of the American people are more *carefully fostered* and *conserved*. Nor can we recall any institution, public or private, professional or commercial, in which the national ideals are more lofty, or the measure of their attainment so great. Here, at least, patriotism is divorced from material profit, and here the Flag is scrupulously honored as the sublime emblem of all that is noblest in the past history and future aims of the American people.

The SCIENTIFIC AMERICAN stands for an adequate navy because, as stated by one of the writers in this issue, the navy has been truly designated as a "great American university," in which nearly 50,000 men and youths are being trained in that "respect for constituted authority" to the lack of which, as much, perhaps, as to anything else, are to be attributed the more serious of our social, commercial and political evils.

We believe in an adequate navy, also, because both at Annapolis and in the subsequent routine of official life, the service has developed a body of men who reach a higher professional standard of ethics than can be found, probably, in any of the professions to-day. In his ever-ready subordination of self-interest to the interests of the service, the naval officer stands for the finest traditions of the professional man; and in the matter of zeal and sobriety, we believe that he has reached a higher mark than any recorded in the past history of the United States navy. We speak of sobriety from the standpoint of intimate knowledge, for it was the Editor's privilege recently, as guest in the wardroom mess of one of our ships, to note that, when the wine was served, one-half of the glasses were turned down—this, mark you, on the score that it tended to efficiency.

Lastly, the SCIENTIFIC AMERICAN stands for an adequate navy, because the national funds expended on the construction of ships and their equipment have served to originate and keep alive not a few of the industries of the country. But for the work afforded by the contracts for new ships for the navy, some of the finest shipyards in the country would have closed their gates, and the death blow would have been given to our all-but-defunct merchant marine.

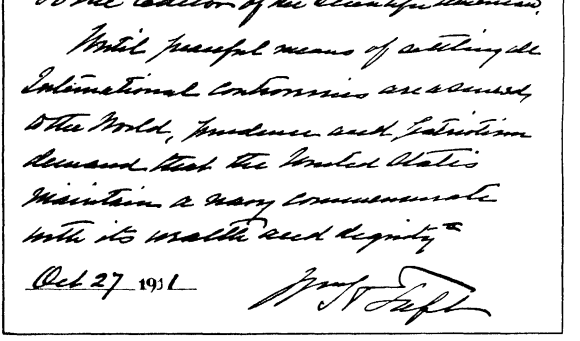
The Business Management of the Navy

By G. v. L. Meyer, Secretary of the Navy

THE essentials of administration are organization, co-ordination and efficient methods.

At the end of the previous administration a beginning was made in consolidating the shops at the navy yards Under the old system, in existence for many years, each bureau had its own shops and its own workmen. Work is now done for any bureau in general shops.

In order that the head of the Navy might be informed and have responsible expert advice, and coordinate the efforts of the bureaus, an organization was put in force December 5th, 1909, with the knowledge and approval of the President, by which four aids were appointed and the bureaus were grouped in divisions of Operations, Material, Personnel, and Inspections. The Aid for Operations has charge of movements of ships, grouping into fleets and squadrons, and preparation of war plans and strategic studies The Aid for Material studies the requirements for repairs and alterations and advises the Secretary as to whether the work in the various bureaus is being co-ordinated and expedited. The Aid for Personnel keeps posted as to the officers and men, and is always in touch with conditions at Annapolis and the training stations.



The Division of Inspections, reporting direct to the Secretary, co-operates with the Division of Material in finding out the condition of the ships and the necessity for repairs, and advises also as to whether repairs and alterations requested will be worth the expenditure of money in final military value. A part of this work was formerly done by the Board on Construction, composed of the individual bureau chiefs Under this board also came the final determination of the qualities of new ships In the present organization, the designs and general military characteristics of ships are determined in a more rational and up-to-date manner The general military features required are recommended by the General Board and are referred to the Bureau of Construction and Repair In case the general requirements asked for cannot be met, they are modified or changed to suit what may be accomplished on a given displacement After the sketch plans are ready, sea-going officers from the fleet and other sources go over these designs, criticise and suggest improvements The modified requirements go back to the Bureau of Construction and Repair for change in the outline plans, which are again submitted to scrutiny. The whole matter has thus been thoroughly gone over and the objections, criticisms and suggestions of the sea-going officers, and the opinions and knowledge of the technical officers have been assimilated. The final designs represent both the best technical knowledge and the sea-going experience of our expert officers. The best naval advice is now placed in the hands of the designer without his efforts being required to reconcile many conflicting opinions, and at the same time the officer who will have to fight the ship finds that his advice is not ignored This method has proved an inspiration to the naval architect, and the present designs of battleships are far in advance of all former attempts.

The Department has been for some time studying the new systems of modern management in commercial establishments, both in this country and in England, with a view to introducing such parts or features of it as might be applicable to our navy yards. Civilian experts who visited the vessels of the fleet found that the highest type of scientific management now exists in our battleships, and they have expressed to me the greatest admiration for the progress so far made and the excellent results accomplished. They found the Office of the Director of Target Practice a fine example of a planning office.

Some form of central planning will probably be added to the present organization, shop methods will be improved, and better determination of the use of machine tools and the efforts of the individual workman will be sought. The Department hopes to secure the best features of successful management and adapt them to navy yard requirements, thus cutting out wastes in time and by better methods securing increased production, with mutual benefit to the government and the workmen If the energy of the workmen is wasted or is not efficiently applied, the elimination of the conditions producing such waste of good energy would be beneficial alike to the government and its employees; for both should share in the benefits of increased production

The Division of Operations has drawn up a new organization for the fleet, to consist of 21 battleships, assigning one to the Commander-in-Chief, leaving five ships in each of the four divisions of the battle fleet But one ship of each division will be at a navy yard for general repair, the other ships coming to the yards only for docking or minor emergency repairs twice each year The efforts to make the ships as self-sustaining as possible have been encouraged, with the result that the work at the navy yards has been reduced The carrying out of these two business-like features in handling the fleet will show more clearly the wisdom of recommendations made last fall that we give up a number of our smaller and unrequired navy yards

One of the chief causes of great expenditures in the Navy is the excessive number of navy yards We have on the Atlantic Coast nine navy yards, where in several instances, money has been expended lavishly, which would not have been the case if the strategic and economic point of view only had been considered

LETTER FROM PRESIDENT TAFT, COMMANDER-IN-CHIEF OF THE UNITED STATES NAVY

Last year, as a beginning, it was recommended to Congress that several stations be abolished which would have brought about a saving, irrespective of the price which the government might have obtained for these properties, of an annual maintenance expense of $1,600,000.

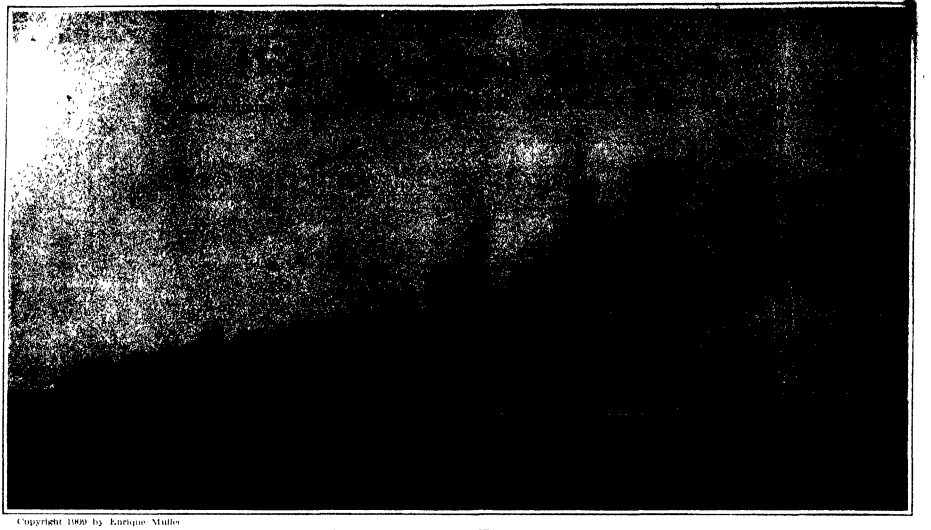
Criticism has been made for my not having recommended the abolishment of any of the Eastern yards, but the reason was that, for the present, the dry docks in the Eastern yards are a necessity to the fleet. The Eastern yards are located at Portsmouth, Boston, New York, Philadelphia and Norfolk, and it might be well to include Charleston. It has been sometimes stated that not more than three or four of these navy yards will be actually necessary, preserving, however, the use of all the large docks for government purposes The question as to which of these yards should be maintained and which abolished is so important that it should be thoroughly considered by an unbiased board of experts, having in mind not local interests but only those of the fleet; as the yards exist for the fleet and not the fleet for the yards As navy yards have no defensive facilities, the army must be consulted as to their protection and defense, consequently, the consideration as to which of these six yards are necessary to the navy from an economic and strategic point of view has been left to a joint Army and Navy Board to determine On their report will be based my recommendations to the President as to the necessity of these yards, and as to which should be developed and continued

When the Panama Canal opens, and the fleet spends probably an equal amount of time in each ocean, the work for the Atlantic yards will be much reduced and it will be even more evident that fewer will be needed By a proper reduction in navy yards, there would be a vast saving of money in maintenance, probably three to four millions a year, and a realization of funds from the sale of real estate If this is not done Congress must assume the responsibility The great importance of the Caribbean Sea as a base of future naval operations, consequent on the completion of the Panama Canal, is now well realized It is the plan of the department to have a naval base in the accessible and suitable harbor of Guantanamo, Cuba, on the direct route to Panama, which is some 700 miles from the Canal, and capable of harboring a fleet of 50 or more men-of-war With a fortified entrance to the canal, a reasonably strong base at Guantanamo, and a torpedo base at Key West, our fleet will be able to utilize its full strength for attack or defense in the Caribbean, and the Gulf of Mexico will be as safe as an inland lake

It is important, during battle maneuvers in peace, or a period of real hostilities, that a vessel should not be called upon to return thousands of miles in order to effect urgent repairs These can be more easily and economically done by the development of Guantanamo as a limited docking and repair station

It is the intention to develop Pearl Harbor, San Francisco Bay, and Puget Sound in order that the entire fleet may be maintained at times on the Pacific Coast

The Department has been working for some time with the President's Commission on Economy and Efficiency toward introducing better business methods in correspondence purchases and other details within the Department itself The introduction of more economical methods in the departments and at navy yards will be facilitated by the new system of accounting which has been established within the last year in the Department and at the navy yards It is now possible to get accurate trial balances, follow the cost of work, and determine with a larger degree of accuracy just what the navy's money is being spent for



It is proposed, also, to reduce to the smallest limits the number of articles manufactured in navy yards, and to buy in open competition, whenever possible, all articles which can be properly and more cheaply made by commercial establishments Naval specifications have recently been simplified and conform more to commercial usage, thus resulting in increased competition and lower prices to the Navy

The occasional building of a battleship or vessel of a special class in a government yard, in order to demonstrate cost, is valuable and instructive, but should be avoided when a large saving ($1,500,000 on a single battleship) can be made On account of the restriction made by Congress in the Naval Act of June 24th, 1910, by which it was provided that one of the battleships therein authorized must be constructed in a government yard, this saving can not be effected

The question of docks for our larger vessels has been, until lately, a serious one It looked for some time as if our latest ships such as the "Arkansas" and "Wyoming," would be finished before any dock would be available to clean their bottoms and have them ready for their trial trips To provide against this, vigorous action was necessary and was taken

Dry Dock No 4, at the Brooklyn Navy Yard, will now be completed in January, 1912, and Dry Dock No 3, at Norfolk, lengthened to 700 feet, was finished in September, 1911 The Pearl Harbor dock and the large dock at Puget Sound, which will accommodate ships of the "Wyoming" class, are being pushed, and the latter is expected to be ready in March, 1912.

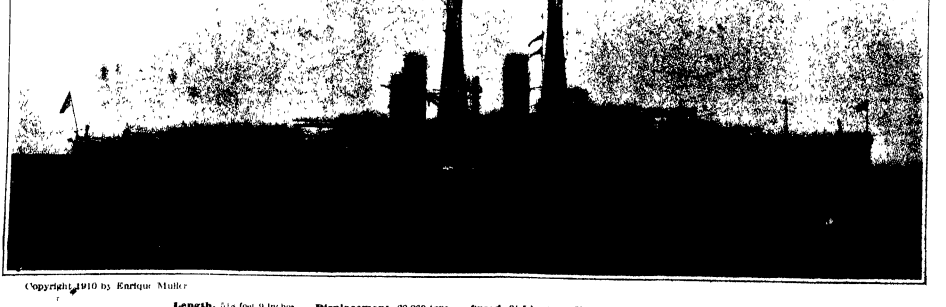
PRE-DREADNOUGHT SHIPS OF THE ATLANTIC FLEET STEAMING IN COLUMN

THE strength of the fleet is commonly measured by the number of battleships and other fighting units on the Navy List. In a way this is correct and yet it may lead to serious error. It is safer to regard the number of battleships, armored cruisers, scouts, destroyers, etc., as only the potential strength, since the efficiency of the fleet, its ability to proceed promptly where needed and engage and overcome an enemy, depends upon many other things than mere ships.



It is pertinent to remind the reader that battleships and even the guns they carry, require years to build, that fighting ships can no longer be built or improvised after the outbreak of war that officers and men can no longer be recruited from the merchant marine and quickly converted into naval crews, and therefore a nation to be ready for war must prepare in time of peace, and if not prepared can have small hope of victory over an enemy more wisely administered. The parable of the wise and foolish virgins is nowhere more applicable than with a naval force. These facts are so often lost to sight, even by many in high places, that it is well to mention them here as a preamble to a discussion which would not be understood or if understood would fail to carry conviction, if they were not borne in mind.

The numerical strength of our fleet, as compared with other leading naval powers, is shown in the tables on page 532.

For several years past only about sixteen battleships have been kept in active service, the remaining vessels of this class together with a number of ships of less importance, being out of commission for overhauling or in reserve for want of a sufficient number of officers and enlisted men to man them. On July 1st, 1911, the battleships in full commission were increased to twenty and shortly afterward to twenty one, while all battleships built, thirty-one in number, will, about the end of this year, be either in full commission, or in reserve with sufficiently large crews to keep them in readiness for service. This great increase in the strength of the fleet is best shown by a comparison of the number of battleships and armored cruisers that were in full commission or in reserve, ready for active service, on May 1st 1910, and the number that will be in readiness about the end of this year, when the reorganization of the fleet being effected by Secretary Meyer will have been fully realized. A similar increase in the effective torpedo fleet, and to a less extent other vessels, has been made, but the most significant fact is of course the increase from 19 to 31 battleships in condition for active service as regards material. A second and no less significant fact is that this large fleet is being created and maintained at a less cost for the entire naval establishment than formerly. The reasons for this are numerous, but the most important may be briefly stated here.

	May 1 1910	Dec 31 1911
Battleships in active service...	16	21
Battleships in reserve, ready for service	3	10
Armored cruisers in active service	10	8
Armored cruisers in reserve	0	2

The most valuable lesson learned from the voyage of the battleship fleet around the world in 1908-1909 was that naval vessels may be practically self-sustaining in matters of repairs, provided the personnel is of a high standard. This fact is the basis of the reorganization lately put into effect, which makes possible the maintenance of the entire fleet in readiness for service. Before the reorganization it was customary to employ ships' crews to only a comparatively small extent in repair work. Vessels once placed in commission were habitually kept actively employed, with frequent visits to the navy yards for necessary repairs, until they deteriorated to such an extent as to require an extensive overhaul, when they were placed out of commission and turned over to the navy yard forces. During their period of commission

major repair work not deemed of immediate importance were permitted to accumulate. This practice resulted in the ships not being in the best condition during the latter part of their commission, in expensive navy yard repairs during their active service; in extremely high cost of general overhaul and refitting after being placed out of commission; and, what is of the greatest importance of all from the viewpoint of preparedness, in the loss of ships to the Navy for anywhere from two to five years during their period of overhaul. In short, the old methods were extremely inefficient and wasteful. Under the system lately adopted ships will not be placed out of commission until they become obsolete and useless for war purposes. They are kept in efficient condition by their own crews and the navy yard work on them is limited to that clearly beyond the capacity of the crews.

The battle fleet is organized in divisions. Each division contains five ships of like or nearly similar tactical qualities. Four ships are required to be ready for service, while the fifth ship is allowed to lie at its home yard for overhauling and repairs by the crew, assisted as far as necessary by the yard force. The ships of a division are given this overhaul period in rotation, or each has about two months' uninterrupted time for repairs once each year. The net result of this is that in a fleet of twenty ships, sixteen are kept ready for service, and the remaining four are in a condition nearly approaching readiness.

Repair work done at a navy yard is very expensive and generally is not of better quality, if as good, as work done by a ship's force. Obviously the difference in cost is very greatly in favor of the ship's force, since the pay of the naval personnel is the same, whether it does the work or stands by and watches the navy yard force do it. As a general rule no one can know the needs of a ship as well as her officers and crew, and no other set of men is as capable as they of doing their ordinary repair work efficiently and economically. But, aside from these considerations, it is essential from a military point of view that the ships' officers and crews shall be habituated to this work in order that they may be able to maintain the fleet in an efficient condition in time of war, when there may be no navy yards at hand. Furthermore, of equal importance is the fact that ships may be kept in practically constant readiness for battle when repairs are habitually taken in hand and completed as rapidly as the necessity arises, while, if a navy yard is depended upon, repairs are allowed to accumulate, and when taken up by the yard require much time to complete.

As stated before, the strength of the fleet and its readiness for service depends upon many other things than mere ships. One of the most important factors is that of keeping all the units in readiness as regards material, as was dwelt upon somewhat at length in the preceding paragraphs, and a second fundamental requirement is that the personnel, both officers and men, must be competent and zealous in their work. Given these two fundamentals, there remain, before the fleet can be called efficient, the constant training of officers and men in their duties, the maintenance of a high *morale*, the inculcation of habits of high moral, physical and mental discipline, the attainment of the highest possible efficiency in gunnery and engineering; and finally, the amalgamation of all the units of the fleet into a composite whole capable of responding to the will of a practised commander-in-chief.

The question as to whether the fleet now meets these conditions and requirements depends upon what are regarded as the standards of efficiency and readiness. In matters of naval preparedness and efficiency the strength of a fleet is ordinarily measured by comparison with those of foreign powers. This method often leads to erroneous conclusions, for, as history shows, the true strength of a fleet can never be accurately determined except by the supreme test of war. The method that tends to the highest state of efficiency is to keep before us a standard of perfection, which if impossible, leads ever to constant improvement.

One of the most potent factors for steady improvement is competition, and to it much of our present efficiency in gunnery and engineering may be attributed. The spirit of competition not only leads to constant efforts on the part of the personnel to excel with the instruments placed in its hands, but stimulates the inventive genius of those charged with the making of the instruments, so that there has been a continual advance in the power and accuracy of guns as well as in the rapidity and expertness of their use. This is exemplified by the remarkable improvement in our gunnery since the Spanish-American war. At that time our fighting range was only two to four thousand yards, and a twelve or thirteen inch gun was fired once in about three minutes, now, our target practice is carried out at a range of ten to twelve thousand yards, and the heavy guns fire two shots per minute, and with this advance in range and rapidity there has been a still more remarkable improvement in accuracy.

The advance in engineering efficiency has been as striking, and almost, if not quite, as important as the advance in gunnery. The reliability of the engines, as shown by full speed trials immediately after long cruisers, is of vital importance, and skill in fitting, with attention to other details, has increased the steaming radius of the fleet from 25 to 40 per cent.

The cruise of the battleship fleet around the world did more than any other one thing to mold our fleet into shape; before that time the fleet may be said to have been an aggregation of units, but the cruise, with its attendant constant exercise in fleet tactics, made these units into one machine-like body. In short the fleet on this cruise found itself. Since then more than ever before, attention has been given to tactical and battle exercises, frequently under conditions simulating war. This more than anything else, except gunnery proficiency, insures readiness for battle. Even the best of ships would meet defeat if incapable of being handled effectively as a fleet.

Twice each year the battleship fleet, the torpedo fleet, and all other vessels available, are concentrated for joint maneuvers and battle exercises under the direction of the commander-in-chief, who thus gains the experience and practice necessary for his final training in the art of war. At other times each year the commanders of divisions of the fleet are given the opportunity to cruise and exercise their commands independently in order to gain experience which will fit them for succession to the command of a fleet.

As previously mentioned, those battleships and other vessels which cannot be kept in full commission, owing to a lack of available men, and to the considerable increase of cost involved, are being organized into a reserve fleet which, as far as their material condition is concerned, will be at all times ready for active service. These vessels are being provided with reduced crews to keep them in condition, and to serve as a nucleus of the full crews which, in the event of war, will be made up from the officers and men employed in time of peace at the shore stations, from the naval militia, and by the re-enlistment of men of previous naval training. This is a long step in advance in the matter of preparedness over the conditions which formerly existed.

The principal requirements of the fleet at present, without considering any increase in its battleship strength, are:

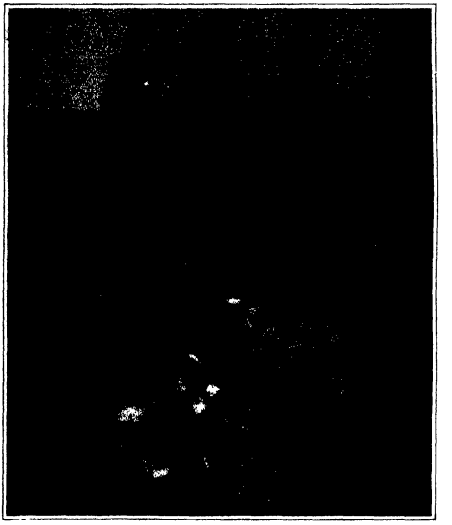
(1) The gradual replacing of worn out or obsolete vessels by newly-constructed ships designed to efficiently meet the needs of the service.

(2) The provision of additional auxiliary vessels, repair ships, supply ships, colliers, tenders to torpedo fleets, tenders to submarines, transports and hospital ships.

(3) Additional scout cruisers, destroyers and submarines.

(4) The organization of an adequate naval reserve.

Battleships have a useful life of about twenty years, during the first half of which they may be considered eligible for the first line, or the main battle fleet, and during the latter half for the second line, or reserve fleet. The comparatively short life of ships is due not so much to deterioration as to the rapidity of development of science and the arts, which renders ships obsolete after ten to twenty years. As a case in point, compare battleships of the "Oregon" class with those of the "Delaware" class, the former launched in 1893 and the latter in 1909. There is not the slightest doubt that one "Delaware" could defeat in action a whole division of "Oregons," or could destroy the entire American fleet of the Spanish-American war. Thus it becomes necessary to replace these obsolete vessels and to relegate them to the coast defense and finally to "scrap" them, use them as targets, or otherwise dispose of them to the best advantage.



Auxiliary vessels are absolutely necessary for the maintenance of a battle fleet. Some such vessels have been provided, and additional ones must be obtained from the merchant marine when war becomes imminent. In this connection our merchant marine is deplorably small and therefore the Navy must be provided with a larger number of regular naval auxiliaries than would be necessary or desirable if enough merchant ships were available.

The necessity for additional scout cruisers of which we possess only three built for that specific use, destroyers and submarines, is apparent from an examination of the tables on page 542 showing the fleets of the several powers. A battleship is dependent largely upon its scouts and destroyers for protection against torpedo attack as well as for the discovery of and attack on the enemy's fleet.

The creation of a naval reserve of officers and men is urgently necessary. The reserve should be composed of men who have had experience on board naval vessels. Thousands of such men pass each year from the Navy into civil life, and while it is expected that a large proportion of them will re-enlist in a national emergency, they should be formed into a reserve in time of peace, so organized that in an emergency they could be assembled at appropriate rendezvous and the reserve fleet manned without undue and possibly fatal delay.

Finally, the whole nation must be awake to the necessity of naval preparedness as a preventive of war. It has been well said that our nation is warlike but not a military one. History bears this out, and it is a fact that all our wars have cost us excessively in life and money because of our unreadiness. Wars are usually of short duration, but preparation is long, and under modern conditions adequate preparation after war breaks out is well-nigh impossible. Our nation leads all others in its advocacy of arbitration. Our propositions are received with respect because of our strength, both actual and potential. To day our interests touch with those of other nations in all parts of the globe, and while good faith and high principles have greater world force than ever, the time has yet to arrive when our national policy, even our national safety, can be held secure without armed forces, and of these an efficient battle fleet is indispensable.

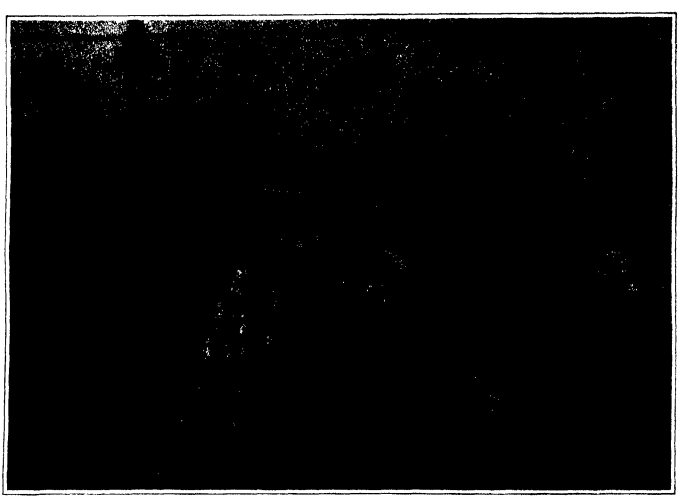
The operations of a fleet are directed mainly by signals from the bridge of the flagship. In the above photograph, at the end of the bridge is seen a semaphore, and above the rail is a signalman with two flags, each of these sends "wig-wag" signals. The signal officer and a signalman are at the rail reading signals from another ship through telescopes.

THE SIGNAL BRIDGE OF A BATTLESHIP

Influence of the United States on the World's Battleship Design

Our Plan of Placing All Turrets on the Center-line Has Become the World's Standard



By Rear-Admiral R. M. Watt, U. S. N., Chief Constructor and Chief of Bureau of Construction and Repair

IT is a well known engineering principle that any design of the first magnitude must be a development of previous practice and based on features gathered from the four corners of the technical world To attempt to trace the origin of many of these features would be a task for a historian and the result would be of small value except as a matter of academic interest In a broad way, however, the history of shipbuilding and designing in the United States shows numerous fields in which Americans have been pioneers or instruments in the highest development of the ideas of others

The well known inventive genius of the American can be recognized as a basic influence in myriad mechanical details incorporated in the great ships of war or peace of all the maritime nations These details though great in their final result, cannot be considered as a direct influence on the design of the individual ship This influence, however, can be found even in the early history of this country when the American clipper ship was the fleetest sailer on all the seven seas From this point to the present day the same influence can be traced through such great events as the marine application of the steam engine, the development of the armored revolving turret for the mounting of heavy guns, the application of electricity to all auxiliary power purposes on board ship, the appearance of the American type of the modern submarine which, in its original form or as a basis for further development, is found today in the navies of England, Japan and Russia, the introduction on war vessels of the many comforts and conveniences of modern life, thereby permitting the fighting personnel to be maintained in the highest state of physical and mental training These and many others are features which, through internal and external sources have influenced, by the agency of American designers, the present-day development of that great fighting machine, the battleship In the consideration of this type it is well to pass over the great events of previous years and the details of today and treat only of those features which, to the naval architect, give a ship an individuality of its own Such a feature is what is now generally known as the "American turret arrangement which it will be interesting to examine in some detail

A battleship has frequently been described as a machine whose output is fighting capacity In the development of any new type of machine, one designer will emphasize some one feature or arrangement, while other designers considering other features of greater importance will make collateral provision for them With the advance of time and increased experience there is a gradual adoption of a standard type of machine, to which all manufacturers more or less conform It is the purpose of this paper to show that the designers of the war vessels of the United States *in their first all-big-gun battleship* adopted as the emphasized feature of the fighting machine a battery arrangement which, after experiment with various other battery arrangements, is now generally accepted by the designers of all nations as the standard battery arrangement (of guns) for the all big-gun battleship In thus setting the standard battery arrangement of fighting vessels, the influence of the United States on the world's battleship design *cannot be overestimated*

The armament—that is the guns upon the number and arrangement of which fighting capacity depends—is the most striking feature of a battleship. In the development of the all big-gun battleship, the designers of the United States naval vessels at once adopted an arrangement of all turrets on the center-line of the vessel whereby at the forward end of the vessel number two turret fired over number one turret and at the after end of the vessel number three turret fired over number four turret In this manner all guns were enabled to fire on each broadside, and naval authorities are practically agreed that not less than 85 per cent of the firing will take place in the arc forty-five degrees forward and forty-five degrees abaft the beam This arrangement was adopted in 1906 by the United States in its first all big-gun vessels, the 'South Carolina,' and 'Michigan,' and the all-turrets-on-center-line arrangement has been followed in all battleship designs for the U S Navy since that date.

All the turrets of our later battleships are located on the longitudinal center line of the ships. This enables every big gun to be trained through a wide arc of fire on either broadside.

THE THREE AFTER TURRETS OF THE "NORTH DAKOTA"

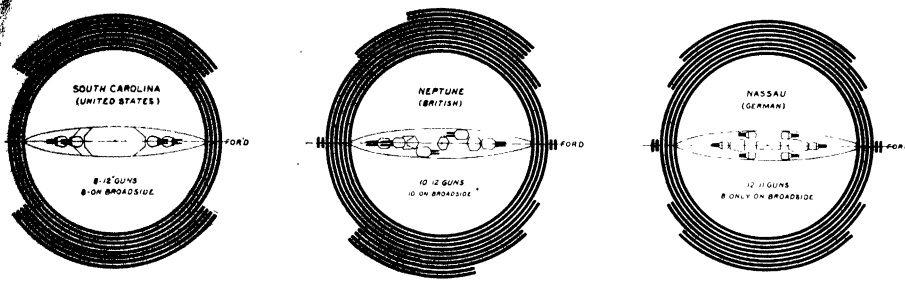
Assigning what we considered undue importance to end-on fire, foreign designers adopted arrangements which gave them end-on fire by the sacrifice of broadside fire to such an extent that from twenty to thirty and more per cent of guns could not be fired on the broadside, where they would most often be required. It should be noted that every battleship of the all-big-gun type in the U S. Navy can fight every gun on the broadside—a provision which does not obtain in any other navy of the world

To-day, however, the wisdom of the "South Carolina" arrangement is generally recognized, and such arrangement is coming into general use in all armored vessel construction

That the importance of the principle of center-line turrets is not merely the view of an interested American naval officer is proven by the following foreign comments

In a paper on "The Armaments of Battleship," contributed by that pre-eminent naval architect, Sir William White, to the American Society of Naval Architects and Marine Engineers in November, 1910, he wrote

"There are two positions for heavy guns which by common consent confer supreme advantages, and are always utilized. These positions are at the center line of the deck; one commanding right-ahead fire, with large arcs of horizontal training reaching well abaft the beam on each side, the other possessing corresponding command right astern and over large arcs of training reaching well before the beam. Until the 'Michigan' and 'South Carolina' were designed it was the general practice to mount one or two heavy guns—two in nearly all cases—in each of these positions. Superposed turrets were tried in some cases, and 8-inch guns were mounted in the upper emplacement; but this practice did not find much favor and may be considered to have dropped out of use. It was a new and bold departure in the 'Michigan' and 'South Carolina' to place two turrets in each of the supreme positions and to arrange for firing the guns in one turret over the top of the other turret. That arrangement proved successful, however, and has been largely adopted in recent ships of all navies When associated with the mounting of guns in pairs this system permits the effective use of eight heavy guns, if three guns are mounted in each turret then twelve heavy guns can be given equal arcs of command, and all the guns can be used on each broadside . . .



"Now there is a marked disposition to place all the heavy-gun stations at the center line of the deck, so that all the guns may be available on both broadsides This is a return to a disposition adopted in the earliest British turret ships built nearly half a century ago. The 'Royal Sovereign' (1863) and the 'Prince Albert' which followed immediately after her, each had four turrets so placed. It may be noted that the United States Navy took the stand in this last movement, and further has the credit of demonstrating the possibility of associating powerful bow and stern fire with the maximum of broadside fire over large arcs of training, by placing some turrets higher than other and firing over the lower turrets on certain bearings"

In commenting on the above paper by Sir William White, *The Engineer*, published in London, says editorially in its issue of December 2nd, 1910:

"In tonnage value for effect obtainable, it is hard to believe that it is possible to improve on the arrangement, first adopted in the United States battleship 'Michigan,' of four twin turrets on the center line, the two inner turrets firing over the two end turrets."

In its annual comments on warship design, "The Naval Annual" for 1910, edited by Lord Brassey, says:

" . . . . The 'Michigan' and 'South Carolina,' of 16,000 tons, have a speed of nearly 19 knots and eight 12-inch guns, all mounted in pairs on the center line, the second and third turrets being on a higher plane than those at the extremities of the vessel, so as to allow of their guns pointing over the end turrets, enabling four guns to be directed right ahead and astern. Now, if they can be so fired without detriment to the outer gun positions, the design possesses the advantage that, with two guns less than our 'Dreadnought,' an equal broadside fire is secured. It only gives, however, an end-on fire of four guns against six. Another novelty in the 'Michigan' and

The eight-gun "South Carolina" of 16,000 tons can deliver a more effective broadside than the twelve-gun "Nassau" of 18,500 tons displacement

is the means whereby elevation is secured for observation, signalling, etc. Masts in some form are required. The tripod method was adopted in the 'Dreadnought.' It is not novel, having been advocated by Cowper Coles and applied to the 'Captain' for sailing purposes It gave less interference with turret-gun fire than ordinary rigging But the three iron masts forming the tripod are of great weight, and probably mainly on this account the Americans have, in the 'Michigan,' placed two masts constructed like an Eiffel Tower of steel lattice work. Though offering a comparatively large target, presumably it is expected that projectiles will pass through without doing great damage; but if the resistance is sufficient to explode a shell a different result may follow"

Jane's "Fighting Ships" for 1907, said

"There is some good reason to believe that taking all things into consideration the 'South Carolina' type is the best all-big-gun ship yet put in hand"

Jane's "Fighting Ships" for 1908, referring to center-line battery arrangement, says

"The disposition of artillery in the 'Delaware' is peculiar, all turrets being in the center line There is little doubt that this design is superior to the echelon system in the matter of training The British 'Invincible' class, though nominally able to bear all eight guns on either broadside, can only do so over a very limited arc of training, while every 'Delaware' turret has a fine arc on either side."

And again in 1910, on page 503 of Jane's "Fighting Ships," Captain William Hovgaard states

"The ideal arrangement of the heavy gun-turrets seems to be the American, first adopted in the 'Michigan,' where two turrets are placed at each end of the ship in the center line, the guns nearest amidships firing over those nearest the ends By this disposition the guns obtain the maximum arc of fire, the position of the upper turrets is commanding and dry, the arrangement of ammunition rooms is simple, and ample room is left amidships for an efficient and well protected secondary and anti-torpedo boat battery With turrets placed on the broadside or on a low level in the center-line between end turrets, these advantages will not be obtained, and notably the relative loss in arc of fire, as in case of the broadside turrets of the 'Dreadnought,' the 'Nassau,' and the new French 23,000 ton battleship, will very considerably reduce the efficiency of the guns

"If then we want to increase the power of the primary battery beyond that obtainable with the 'Michigan' arrangement, and without abandoning the said advantages, three ways are open

"(a) A third twin-turret may be placed on the center-line at each end of the ship inside the two other turrets and firing over these

"(b) The caliber of the guns may be increased

"(c) Three guns may be mounted in each turret"

Commenting on the visit of the United States fleet to Europe, the *Journal of the Royal United Service Institution* for December, 1910, states

"It may be of interest to recall that the two American dreadnought battleships, the 'Delaware' and 'North Dakota,' are vessels with a displacement of 20,000 tons, and in addition to their main battery, composed, like that of our own earlier dreadnoughts, of ten 12-inch 45 caliber guns, they also carry a more powerful anti-torpedo defence armament of fourteen 5-inch Q F guns, which for the most part are mounted in a central battery behind armor protection All the big guns are on the center line of the ship, this being a characteristic feature of the turret arrangements in American designs, two of the turrets being raised above the others in order to obtain a sufficiency of right ahead and right astern fire and this method of placing the turrets in the one now adopted for our latest ships, as giving the advantage that all the guns can be fired on either broadside Thus, while the 'Dakota' and 'Delaware' can bring all ten of their 12-inch guns to bear on either side, our earlier dreadnoughts including the 'St Vincent' and her sisters, can only bring eight On the other hand, the end-on fire of our ships is heavier"

It should be noted that the *same* arrangement of the turrets of the 'South Carolina' and 'Michigan' was not the result of chance, but was adopted only after actual experiments on the monitor "Tallahassee" (then the "Florida") had proven that it was possible to fire a 12-inch gun over a turret without injury to the occupants of the lower turret It is believed that the battery arrangement of the "South Carolina" and "Michigan" will remain a standard arrangement in the future, and that further increases in fighting capacity will be secured by increasing the caliber of guns, or by increasing the number of guns in a turret, or by both measures in the all-center line vertical echelon turret arrangement

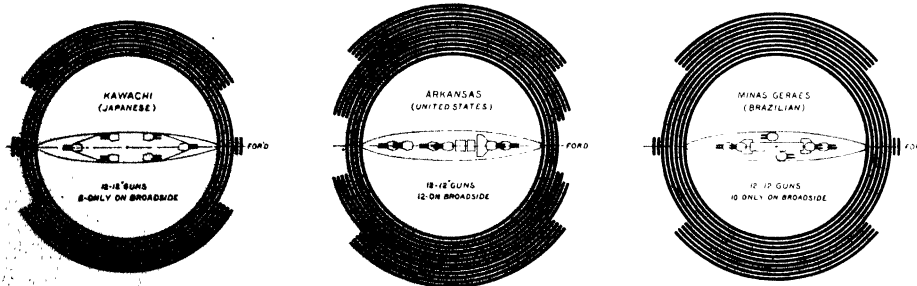
The Business Management of the Navy

(Continued from page 513)

The width of the latest docks has been increased to 110 feet, the same as established in the locks of the Panama Canal

Two contractors having failed to secure results with the New York dock, the second contract was ordered to be cancelled on account of no progress having been made, and competition for the completion of this important work was limited to the six largest firms of recognized engineering ability and financial standing The contract, placed in November, 1909, under these conditions, is being well carried out and the great dock at the New York Navy Yard will be finished in January, 1912

The large dock at the Boston Navy Yard was enlarged slightly, at a cost of only $15,000, so that it now can comfortably dock the 'Florida' and "Utah"



Competition, both in the fleet and at navy yards, has been a great factor in reducing the expenses of a growing fleet The present high standard of shooting is due to the system of competition introduced some ten years ago Comparison between the shooting in 1898 and to-day shows that to-day we are 1,200 times better

Steaming competitions have lately been introduced, so that economy in the use of coal oil, waste, and other supplies, and the efficiency in steaming determine the ships' standing The idea is that a ship must be able, first to get on the battle ground quickly and surely, when she is there, she must be able to shoot rapidly and straight

Instead of having seven store accounts we now have but one, which has simplified book keeping and clerical work The old Naval Supply Fund, which had a capital of $2,700,000 has been liquidated and this sum has been released to the Treasury for other purposes

It is hoped that a correct personnel bill will be secured, by which the ages of our officers may be reduced and greater efficiency brought about The bill recommended will produce captains from 45 to 48 years of age and rear admirals at 55 instead of about 60 It is also desired to add two vice admirals and an admiral, in order that the commander-in-chief of our great battleship fleet should have a position commensurate in importance with his command and that he should not be outranked, when meeting foreign fleets on special occasions, at home and abroad by an admiral of a single ship or of an inferior navy

In conclusion, let me add that the aim of this administration has been to introduce into the management of the navy modern, efficient business methods, to reduce correspondence and cut out red tape Economies have been established and output increased Nor has the department, in its efforts to reduce expenses, forgotten the paramount importance of the highest military efficiency and a preparedness for any emergency. To-day, when needed it holds, to preserve the peace, a larger and more efficient fleet at a smaller cost for upkeep The changes in organization have justified themselves by results and are paying—the final test of all business management

The "Arkansas" can concentrate on the broadside two more guns than the Brazilian "Minas Geraes," and four more than the Japanese "Kawachi."

Propelling Machinery for Naval Vessels

Review of Present Conditions and Future Possibilities in Motive Power

By Rear-Admiral H. I. Cone, U. S. N., Engineer-in-Chief and Chief of Bureau of Steam Engineering

THE advent of the turbine has greatly extended the range of speed at which vessels may be safely and continuously propelled by steam machinery. It is, therefore, particularly suited to high speed vessels.

In the older destroyers a sustained speed of 30 knots necessitated driving the reciprocating engine at or beyond its limit of safety and reliability. As a result the contract speed could rarely be maintained on service, and certainly not for any extended period of time.

To-day the steam turbines of our destroyers can be driven continuously at full power as readily as at the lower powers.

Next below the destroyer in the speed scale is the scout cruiser, of these we have three, the "Birmingham," "Chester" and "Salem," similar in design, except as regards their machinery installations. The "Birmingham" has reciprocating engines, the "Chester," Parsons turbines, and the "Salem" Curtis turbines. The contract trial speeds were: Birmingham, 24.325 knots, "Chester," 26.52 knots, and "Salem," 25.947 knots, thus demonstrating, as in the case of the destroyers, the superiority of the turbine for development of high speed.

A rather unexpected result of our experience with these vessels on service has been the greater reliability of the reciprocating engine. In the case of this type of vessel, where the reciprocating engine is admittedly out of place, it was confidently expected that the turbine would demonstrate its superiority in this regard. Thus far, however, under similar conditions of service, the machinery of the "Birmingham" has required considerably less repairs than that of either turbine vessel, and of the three, the "Birmingham" has always been the one whose availability for service could most be relied upon.

Thus for the scout cruiser, while the turbine is the most suitable type of machinery, its superiority over the reciprocating engine is not so manifest as in the case of the faster destroyer.

As we descend the speed scale into the region of the more important naval vessels of medium speed, the turbine is still less clearly indicated as the best type of propelling engine. This is because of the relatively increased importance of its principal deficiencies which are:

(1) A tendency to disablement to a degree requiring repairs beyond the capacity of the ship's force, thus temporarily destroying the military value of the vessel.

(2) A lack of economy of steam consumption at the lower speeds which affects the cruising radius of the vessel.

Regarding the first of these, there is a tendency to a rubbing and stripping of the turbine blading due to the small clearances necessarily employed, the causes of which are sometimes obscure, and the prevention of which is accordingly difficult.

The reblading of a damaged turbine can be done only at a navy yard, and requires the lifting of the casing and the rotor, which in itself is a considerable item. In our experience this work has seldom been completed within a month.

Improvement in design, greater experience with the operation of the turbine, and better facilities for its repair will doubtless reduce somewhat the extent and importance of this trouble. But at present the reliability of the turbine in service must be considered as probably not as good in a medium or low speed vessel as that of the reciprocating engine in its present development, with forced lubrication of its bearings.

Inferiority of the turbine in its economy at the lower speeds is probably inherent. At the cruising speed of a battleship the reciprocating engine is 20 to 30 per cent more efficient than the turbine.

These failings of the turbine are due in a great degree to the conditions governing its use in naval vessels, and are not manifest in its other applications. When driven continuously at high-speed, as with electric generators, and, to a less degree, in high-speed passenger vessels, its efficiency as compared with that of the reciprocating engine is entirely satisfactory, and in a vessel the nature of whose service is such that the turbines can be kept warm during the short intervals between runs the danger of stripping during the warming-up period largely disappears. The irregular movements of naval vessels however with their frequent periods in port with cold turbines and their considerable cruising at low speeds impose handicaps on the turbine in these two respects.

The peripheral speed of turbines for maximum efficiency should be not less than half the velocity of the steam. To secure this maximum efficiency within practicable limits of diameter of the turbine requires, ordinarily, revolutions per minute of from 1,500 to 3,000. These speeds are perfectly practicable for electric generators, but are unsuited to the marine propeller, whose efficient working requires revolutions, depending upon its diameter, of from 70 to 800 per minute.

There is presented, therefore, the problem of providing a method in which a high-speed turbine may be made to drive a slowly revolving propeller, thus conserving both turbine and propeller efficiencies.

Two methods of accomplishing this are particularly prominent just now.

Reduction-Gear Drive.

The collier "Neptune," built by the Maryland Steel Company at Sparrow's Point, Maryland, has been equipped with reduction-gear machinery constructed by the Westinghouse Machine Company. This collier is a twin-screw vessel, displacing 19,300 tons, with a

The turbines, shafting and propellers of a triple-screw destroyer, assembled in the shops.

speed of 14 knots. Steam at a pressure of 200 pounds is supplied to a Westinghouse Parsons turbine for each shaft, each turbine developing about 3,600 shaft horse power on 1,220 revolutions. Between the turbine and its propeller shaft is mechanical gearing which will reduce the propeller speed to 135 revolutions per minute at about 14 knots. The gear pinions are carried in floating frames supported by oil pistons in such manner as to effectually take up any irregularity in the gear cutting. The oil pressure on pistons is indicated on gages which afford a means of directly reading the tooth pressure, and thus calculating the power being developed. A novel feature of the installation is a provision for operating the propelling machinery from the bridge. The shop tests of the gearing for the "Neptune" have been very satisfactory. The gears have demonstrated an efficiency of transmission in excess of 98 per cent, and have run quietly for long periods with no apparent wear. There is no back lash on reversing.

Extensive trials of the "Neptune" will be held.

Reduction gearing as installed in the cargo steamer "Vespasian" by the Parsons Company has successfully completed a year's trial, during which its durability has been tested under the severe conditions of weather in the North Sea during the winter months. The vessel has made 32 trips, a total of about 20,000 miles, carrying coal from the Tyne to the Continent and returning with water ballast. It is reported that during this time there has been no appreciable wear in the teeth of the gearing, and that there is practically no slackness apparent, although no provision was made of adjustment for wear. A noticeable feature of the installation has been the almost entire suppression of the tendency to racing of the engine, even in weather when the propeller has been entirely out of water.

Electric Propulsion in a Naval Collier.

In the naval collier "Jupiter," a vessel similar to the "Neptune," which is being constructed at the navy yard, Mare Island, California, there will be obtained a trial of a method of electric propulsion. A contract for this machinery has been placed with the General Electric Company. In this system it is proposed to install one turbo-generator running at a maximum speed of about 2,000 revolutions per minute, and delivering current with a potential of 2,300 volts to induction motors, one on each propeller shaft. The power from the turbine will be transmitted to the propeller shafts, electrically, with a speed reduction in ratio of 18 to 1. The efficiency of transmission is expected to be about 91 per cent. The water rate for this installation is stated to range from 12.15 pounds per shaft horsepower at 14 knots, to 15.55 pounds at 10 knots.

In the case of a battleship the proposed form of electric drive contemplates two turbo generators driving two motors on each of the two main shafts. This multiplicity of units combined with a pole-changing device on two of the motors, promises an economy close to the maximum at all speeds above 10 knots.

Comparing the electric with the mechanical reduction gear it is at once evident that the latter has the superior efficiency of transmission. In the case, however, of a vessel in which economy at the lower speeds is required, the flexibility of the electric installation, as outlined for a battleship, might overcome this disadvantage.

As with the scout cruisers, we will, therefore, probably have in service three similar colliers with different types of propelling machinery, the "Cyclops" being already in commission with an excellent installation of reciprocating engines, which on trial developed a horse-power on less than 1.5 pounds of coal per hour at full power.

Combination of Turbines with Reciprocating Engines.

The combination of a reciprocating engine working the steam from boiler pressure down to nearly atmospheric pressure, and a turbine which works from the exhaust pressure of the reciprocating engine down to the vacuum, is a particularly efficient one, because under such conditions each engine is working in the pressure range to which it is best suited. Such combinations are used with great success in power plants on shore and in certain moderate-speed passenger vessels, notably the "Olympic," "Titanic," "Laurentic," and "Otaki." Its principal value is in economy of steam consumption at full power in a medium speed vessel, in which case it probably gives a gain in economy over the reciprocating engine or turbine of not less than 10 per cent. In the case of naval vessels whose cruising speed requires only from 1/7 to 1/12 of full power, the advantage of this combination is not so impressive.

There is, however, a combination of reciprocating engine and turbine which has its maximum efficiency at the cruising speed. This consists in the use of a small reciprocating engine in a manner similar to that of the cruising turbine in a Parsons turbine installation. The reciprocating engine, whose size is limited to that required to pass the steam for the designed cruising speed, exhausts through the turbines. At higher speeds the reciprocating engine is disconnected. The weight of the reciprocating engine, and the space required, are less than for the cruising turbines, and it is probable that the engine will be less prone to disablement than the cruising turbine. The principal difficulty involved seems to be the design of the clutch connecting the reciprocating engine with the turbine shaft.

In another combination which suggests itself, and which, theoretically, has about the same efficiency, there is substituted for the reciprocating cruising element a small high-speed turbine connected by reduction gearing to the main turbine shaft.

The selection of machinery for a naval vessel at the present time, therefore, requires a careful consideration of a number of possible types. The line drawings on page 519 show the approximate appearances of systems which have been considered for a battleship.

Heavy-Oil Engine.

It now seems probable that none of the foregoing methods of propelling medium-speed naval vessels,

...which are forms of steam machinery, will endure. This in consequence of the recent remarkable development of heavy-oil engines of the Diesel type in Europe. Hitherto, oil engines have not merited much consideration for large naval vessels on account of the limited power that could be developed in a single cylinder. An installation of any considerable power required a multiplicity of cylinders. Now, however, we are credibly informed that 1,000 horse-power has been developed in a cylinder about 33 inches in diameter with a 40-inch stroke, at 150 revolutions per minute, in a 2-cycle marine type reversible engine. This engine has a speed control that is satisfactory, and an economy of fuel consumption probably twice that of a steam engine. An experimental double-acting marine engine, with three cylinders, of about this same size, has been built to develop 6,000 brake horse-power at 150 revolutions per minute. In the development of the oil engine, the trunk piston is being abandoned and cross-heads and connecting rods used. It will, therefore, resemble the reciprocating steam engine, and our experience with the latter will prepare us for the operating and repairing of the oil engine.

As in the case of all first installations of whatever type, there will probably be disappointments in the first applications of the oil engine in marine propulsion, and it may be that further development of the engine may be found necessary prior to its extensive adoption. However, the superior economy of the oil engine, together with the elimination of the steam boiler and condenser will cause us to be patient in the face of a considerable amount of trouble.

The extent of the adoption of the oil engine by the nations of the world will be largely affected by the supply of oil available. We are in a particularly fortunate position in this respect, producing as we do two-thirds of the world's supply.

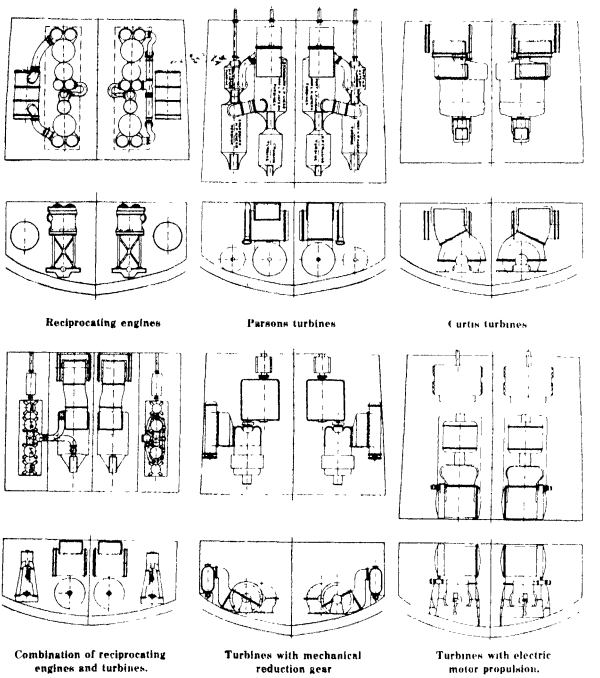
Use of Fuel Oil in Place of Coal.

In our new construction we are greatly extending the use of oil in steam vessels. All our new destroyers are oil burners, and it is hoped to extend its use to the larger vessels, including battleships. Some of the advantages of oil as compared with coal are as follows:

With oil an evaporation per pound of fuel greater than with coal in the ratio of about 14 to 9, and per square foot of heating surface in about the ratio of 10 to 8, is obtained. Fuel oil can be taken aboard readily without manual labor and without interruption to the routine of the ship.

Steam for full power in such a vessel can be maintained as readily as for low power. A vessel burning oil is capable of prolonged runs at full speed limited in length only by the supply of fuel. There is no reduction in speed due to dirty fires or to difficulty in trimming coal from remote bunkers.

There are no cinders and the amount of smoke can be controlled.



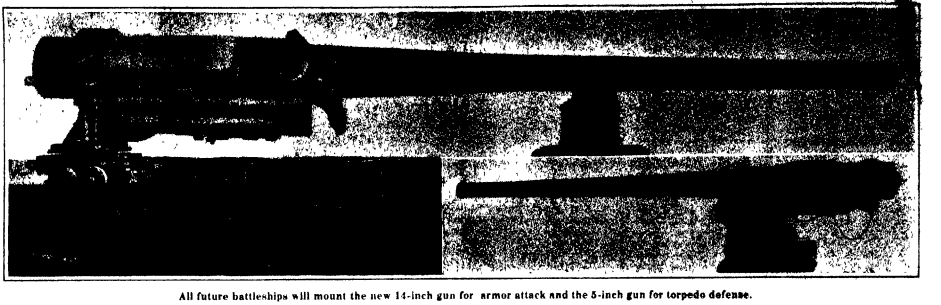
A considerable reduction in personnel is possible, the size of the firemen force required being limited to that necessary for overhaul and cleaning of the plant.

The weight and space required for boilers is reduced first by the reduction in heating surface required and second, by the shortening of firerooms, no space being required in front of boilers for handling the tools.

Coal and ash handling gear is eliminated. This renders unnecessary the piercing of the hull for coal trunks and for discharges from the ash ejectors or ash ejectors.

The stowage and handling of oil is much easier than of coal, and will result in a much cleaner ship and consequent increase in time available for drills.

The mechanical supply of fuel to the boilers gives a prompt and delicate control of the steam supply, permitting more sudden changes in speed than with coal, which is a tactical advantage.



ENGINE ROOMS OF SAME SIZE AS "DELAWARE'S" (RECIPROCATING) EQUIPPED WITH VARIOUS TYPES OF PROPELLING MACHINERY

Speed of turbine, 1,220 revs. per min. Speed of propellers, 135 revs. per min. Efficiency of reduction gear, 98 per cent.

TURBINE AND MECHANICAL REDUCTION GEAR OF THE U. S. COLLIER "NEPTUNE"

All future battleships will mount the new 14-inch gun for armor attack and the 5-inch gun for torpedo defense.

Recent Development in Ordnance

Demand for Higher Efficiency Met by Our Latest Guns and Armor

By Rear-Admiral N. C. Twining, U. S. N., Chief of the Bureau of Ordnance

PROGRESS in ordnance matters during the past year has been rather in the direction of improvement and development of previously existing types than in the line of marked changes. Naval warfare has not been "revolutionized," nor has any such upheaval been even faintly indicated. The increasing efficiency of the submarine boat of the torpedo and of the aeroplane has caused ordnance officials and the navy in general to look ahead to the time when the development of these weapons and methods of attack might demand changes in ordnance or in ship construction to meet them, and tentative plans for such changes have been considered. The aeroplane can not, as yet, be regarded as a material factor in naval warfare, but its possibilities in the future cannot be neglected. The submarine boat and the torpedo have long been elements to be reckoned with, and their usefulness and efficiency are on the increase.

The gun remains the principal offensive weapon afloat and armor the principal element of passive defense. The battle between the two, which has been so often declared lost or won by one or the other, still goes on, though the gun seems to have rather the better of it at the present moment. Already there are rumors of larger and more powerful guns and of armor of greater resisting power. A year ago no modern vessel built or planned carried a gun of caliber greater than thirteen inches, and all of the latest battleships were armed with guns of 12-inch caliber. To-day there are numerous ships building at home and abroad which are designed to carry 13.5-inch and 14-inch guns. Armor's answer to the bigger gun is, so far, increased thickness, but new processes of heat treatment and the introduction of new alloys are rumored, which will restore the former thickness with greater resisting power.

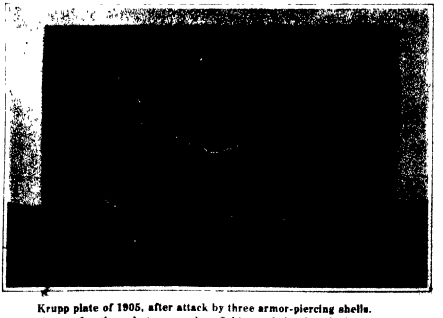
Guns.

The "all-big-gun" battleship of the present day has its prototype in the British "Dreadnought," dating from 1906. Since that date all the principal maritime powers have shown a tendency to confine themselves to battleship design of this type, the main battery consisting of from eight to twelve guns of the largest caliber, mounted in turrets, and the torpedo defense battery of from twelve to twenty or more guns of smaller caliber mounted in broadside.

In the United States Navy the standard heavy gun is at present the 14-inch, 45-caliber gun, while for torpedo defense a 5-inch, 51-caliber gun is used. The following table shows the superiority of these guns over previous types:

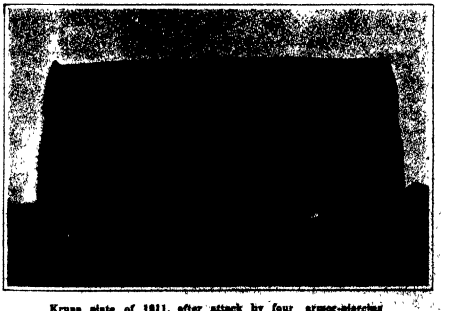
Caliber, Inches.	Length in Calibers	Length in Feet.	Weight in Tons	Muzzle Velocity, Feet per Second.	Weight of Shell, Pounds.	Muzzle Energy, Foot Tons	Extreme Range Striking Energy, Foot Tons	Penetration in Krupp Armor, Inches
5	40	17	3 1	2300	50	1692	7000	8 8 at 6000 yds.
5	51	22	5 0	3150	50	3439	12000	8 0 at 6000 yds.
12	45	45	53 6	2650	870	66894	32000	15 8 at 10000 yds.
12	50	50	56 1	2900	870	81644	36000	15 0 at 10000 yds.
14	45	54	63 8	2600	1400	86587	21000	15 9 at 10000 yds.

An examination of this table shows that the latest turret guns and torpedo-defense guns are markedly superior to their predecessors. The superiority of the 10-inch gun over the 12-inch, 50-caliber gun is due in part to the greater steadiness of the projectile in flight due to its greater weight. The "hitting power" of the gun is greater than that of its predecessor in spite of the fact that its extreme range as mounted on board ship is less.



On page 521 are shown the breech and breech-plug of the 14-inch gun, together with an armor piercing shell and powder charge. The shell shown is of the latest "long point" variety, while the powder charge represents the present practice of putting up smokeless powder in silk bags laced on the side to make them rigid. An idea of the length and general size of the 14-inch gun with the slide in which it is mounted in a turret can be gained from the illustration above.

The latest type of gun and mounting for torpedo defense is shown below the 14-inch gun. This gun may be regarded as effective against torpedo boats at its extreme range of 12,000 yards provided the target is visible, at night or in other circumstances rendering the target invisible, the gun is naturally helpless.



Modern high-powered guns using smokeless powder charges have been proved to have a practically unlimited life under normal conditions of firing, but they erode in the bore very rapidly owing to the high powder pressures they must sustain, and the consequently high temperatures. This erosion is probably due to the action of the powder gases on the metal of the gun as softened by the high temperatures to which it is exposed—about 4,000 deg. F. As the parts of the gun not immediately in contact with the gases suffer no deterioration, the life of the gun may be indefinitely prolonged by renewing the bore. This process is known as "re-lining" and has hitherto consisted in boring out the interior of the gun (to a depth of about one inch in the case of the 12-inch gun) shrinking in a new tube, and then boring and rifling. The facility of re-lining will be enhanced and the cost of the operation will be greatly reduced in the future by building all new guns with conical liners, susceptible of easy removal. The time of re-lining a gun will thus be reduced from seventy-five to twenty-five days.

Gun Mountings.

For a number of years past rumors have been periodically current that this or that foreign country was about to incorporate a three-gun turret in some new battleship. Such advantages as such a system have heretofore presented were mainly in the direction of economy of armor weights, it being readily demonstrable that six guns can be protected with less weight of armor if mounted in two turrets than if mounted in three. There have been, however, countervailing disadvantages in the increased complexity of ammunition supply, turret machinery, concentration of

Krupp plate of 1905, after attack by three armor-piercing shells. No perforation, but excessive flaking of hardened face.

Krupp plate of 1911, after attack by four armor-piercing shells. No perforation and practically no flaking of surface.

SIX YEARS' IMPROVEMENT IN ARMOR PLATE

weight, and other features of the system which have rendered its adoption inexpedient. The time seems now to have arrived when the necessities of ship design and tactical considerations have forced the triple mount and it is interesting to note that Russia, Austria, Italy, and the United States have all incorporated them their latest battleship designs. It is now decided that United States battleships Nos. 36 and 37 will each carry the triple turrets as a part of their main armament. These turrets will embody certain new ideas in gun mountings which have not yet been embodied in any foreign design

For secondary gun mountings compactness and lightness are essential, but to attain them without sacrificing the rigidity which is necessary for accurate firing requires ingenuity. The mounting for the 6-inch, 51-caliber gun, shown on page 520, is the latest type of this kind of mount which has taken concrete form.

Ammunition.

A nitro-cellulose smokeless powder continues to be the standard propellant for use in our naval guns It is extremely satisfactory in stability, ballistic characteristics, and keeping qualities Powder of the same characteristics and composition is used by the army and it may be safely claimed that there is no better smokeless powder in the world. This powder consists essentially of cotton dissolved in nitric acid, then dried, colloided, and pressed into the desired form of grain.

The colloided material is placed in a press, from which it emerges in long strips and rods. These are then cut up into short lengths of the particular size for the powder grain desired The grains are of different sizes for guns of different calibers, being larger, of course, for the larger calibers. Certain varieties of black and brown powder are still in use for loading shell or for saluting purposes The prismatic brown powder was the immediate predecessor of smokeless powder.

The navy powder is manufactured in lots of from 25,000 pounds to 100,000 pounds, depending on the caliber of gun for which it is intended. Methods of manufacture have been so perfected that these powders, when not unfavorably affected by climatic and other unfavorable conditions, retain their qualities and are serviceable for from twelve to fifteen years In case deterioration occurs due to such conditions, ample warning is given by the physical appearance of the powder, so that no spontaneous explosion or combustion is ever to be apprehended; it is, in fact, extremely doubtful whether spontaneous combustion is possible, unless the powder should be subjected to abnormally high temperatures.

Powder which has changed in character to such an extent as to reduce its ballistic value is now re-worked and made over into new powder of the best quality at a small cost. The re-working consists of grinding the grains in water, drying the resulting paste, and then pressing it into rods or ribbons as required; the methods pursued are much the same as those used in original manufacture.

Smokeless powder possesses many points of superiority over black or brown powder) one of the best known is the fact that its combustion produces but little smoke; such as is produced is largely gaseous in nature, containing very little solid matter, and it is, therefore, quickly dissipated This fact gives to the use of smokeless powder a great tactical advantage for military and naval purposes A second point of superiority lies in the fact that the combustion of smokeless powder is practically complete, there being an exceedingly small percentage of solid residue remaining; the whole mass of the powder is, therefore, converted into gas, the expansion of which imparts velocity to the projectile

The particular form of grain in use for all guns of large caliber is what is known as the "multiperforated" form, in which the cylindrical grain is pierced by a number of longitudinal holes When such a grain is ignited the burning progresses both from and toward the center with the result that the burning surface is practically constant until the grain is entirely consumed In consequence of this fact the volumes of gas produced in any two units of time while the projectile is in the gun and traveling toward the muzzle are nearly equal, and the maximum pressure on the walls of the gun is not so much greater than the mean pressure as to require that the breech of the gun be made enormously heavy as compared with the chase and muzzle, as was the case with guns designed for use with quick-burning black powder

The quality of projectiles is being slowly but surely improved. The possible range has been increased by changing the form of the head from the blunt type in general use in recent years, to a long, sharp ogival The above illustration shows the present type of shell for guns of 5-inch to 14-inch caliber The point of the shell, in all except the 5-inch, is a separate piece from the remainder of the shell and is made of soft steel, the body of the shell is of very hard and tough forged steel, containing alloys of nickel, chrome, vanadium and other metals. It is in the quality and composition of the steel used, and in the methods of treatment, which give the shell hardness without brittleness, that the principal improvements have been made in recent years. These points are, in the main, manufacturers' secrets, not disclosed even to government officials.

The function of the soft steel cap is to support and guide the hard point of the shell and thus enable it to "bite" and penetrate the armor on impact. The addition of this very simple device to steel shell increases their penetrative efficiency fully 20 per cent Such caps have been in use for a number of years, it is only their form that has been recently changed

High-explosive bursting charges are a necessity in modern armor-piercing shell The walls of these shell must be very thick in order that the shell may withstand the terrific shock of impact on armor and that it may penetrate, the interior cavity is thus too small to contain a sufficient amount of "gun powder," as commonly understood, to disrupt the shell The use of a more powerful explosive is therefore necessary.

As an alternative to the adopted method of attack on armor i. e., by means of a projectile designed to penetrate and explode inside, the method of attacking with shell exploding on contact has been suggested and has been strongly urged by some persons of undoubted knowledge and attainments The latter method depends for its efficiency on smashing or displacing the armor by the force of the impact and the intensity of the resulting explosion Experiments have been made along these lines from time to time, but, while the damage done to an armor plate by the detonation of a quantity of high explosive in contact with it is admittedly great, it has not yet been demonstrated that a charge of any explosive which can be safely fired from a gun can effect as great damage in this way as can be effected by detonating inside a vessel an equivalent charge of explosive which can be so fired The "Puritan" experiments only confirmed the official opinions previously held on this point

Relative size of naval shells from 5-inch to 14-inch

The powder charge, weighing 370 pounds, discharges the 1,400-pound shell with a muzzle velocity of 2,600 feet per second, and a muzzle energy of 65,687 foot-tons. At 10,000 yards the shell will penetrate 15 9 inches of Krupp armor.

SHELL, POWDER, AND BREECH MECHANISM OF THE NEW 14-INCH NAVAL GUN

Torpedoes.

The torpedo continues to be held in great favor as a weapon of under-water attack, and it must be admitted that no navy has at present an adequate system of defense against such attack if efficiently delivered Torpedo nets as carried by the vessels of some foreign navies are ineffective since torpedoes have been designed which can cut, penetrate or displace the nets The searchlight is ineffective, since a torpedo may be successfully launched at a range beyond its reach Gunfire is ineffective against an invisible target and the torpedo boat can launch its weapon while still invisible to the gun Pickets and scouts are not thoroughly effective, since they may, themselves, be attacked and disabled, or they may be eluded The practical torpedo of the present day may be effectively used at a range of 8,000 yards, a range of 10,000 yards at 27 knots speed is confidently expected in the near future The United States Navy now has in course of building two types of torpedo which will, beyond a doubt, fill these conditions and may exceed them The reliability of the torpedo in the hands of the general service is, unfortunately, still questionable and many failures and wild shots are to be expected There is, however, nothing mechanically impossible in the conditions of the problem of making torpedoes reliable, and recent advances in this direction justify the hope that in the near future a thoroughly accurate long-range weapon will be produced

The "Vesuvius," built for discharging so-called aerial torpedoes, is now employed at the Newport Torpedo Station as a torpedo testing vessel

(Continued on page 534.)

Rank of the United States Among the Naval Powers

Our Present Standing Threatened by the Lack of Colliers and Other Auxiliaries

By Capt. T. M. Potts, U. S. N., Chief of the Office of Intelligence

THIS question has been very often asked of late as to how the United States Navy ranks among the naval powers. Ordinarily, this question is answered by giving a tabulated statement of the effective war tonnage of the various nations and establishing their rank with one another in accordance with the amount of their displacement. This answer is accepted by most laymen as being conclusive, but to naval officers and students of naval affairs it is far from being so. To naval officers two questions naturally arise: What constitutes Naval Strength? How is Naval Strength measured? Therefore, in attempting to fix the rank of the United States Navy with reference to that of other powers, consideration must be given—not only to battleships, but to all the various types of vessels which go to make up an efficient well balanced fleet; to the Merchant Marine upon which a nation must draw in time of war for certain types of ships, and lastly to personnel, active and in reserve, all of which go to make up a well organized navy and measure its strength.

Fleets are created and maintained for offensive operations, and while often spoken of as the mobile defense of a country, the defense lies in the fleet's ability to assume operations against an enemy's fleet, or against the coast or territory of an enemy.

The table below shows the composition of the fleets of England, France, Germany, the United States and Japan, and includes vessels which will probably be in commission or ready for commission on January 1st, 1912.

The launching of the first all big-gun battleship the Dreadnought, in England in 1906, completely revolutionized modern battleship construction—so far as offensive power is concerned. The question of an all big-gun ship had often been discussed and elaborated upon by other nations, but the English were the first to put these ideas to a practical use. All-big-gun battleships constitute a distinct type, and all ships launched since that year have been spoken of as dreadnoughts. The building of this ship placed the navies of all powers upon an entirely different status from that which they had previously occupied, for the Dreadnought completely eclipsed in offensive power all ships previously built. Earlier ships, however, so long as they are employed in the active service of navies, cannot be considered as absolutely obsolete at the present writing, but in a few years, as the number of dreadnoughts increases, they will undoubtedly be relegated to the second line.

Another type of warship, commonly known as the battleship-cruiser, has developed within the last five years and bids fair to be an important factor in all future naval engagements. The first of these ships was launched by England and called the "Invincible," so that the term Invincible is now considered to represent a distinct type of a battleship.

In analyzing the composition of the various fleets of the world, fighting or capital ships, as they are now termed, may be divided into three distinct classes, pre-dreadnoughts, or ships that were built or laid down prior to 1906, dreadnoughts, or all-big-gun-ships, and Invincibles. Battleship-cruisers, with a very high speed, carry a smaller number of heavy guns, of the same caliber as those of modern battleships, and their protection has been somewhat reduced. They must, however, be considered as capital ships.

The table shows that the total warship tonnage of Great Britain is considerably more than double that of any other nation, and, therefore, entitles Great Britain to the position of first in the rank of naval powers. When we come to consider the naval strength of other powers, we find a difference of only about 15,000 tons in the warship tonnage of Germany and the United States, a difference which a layman would probably consider a negligible quantity, or in other words, that these two countries were practically on the same footing. The character of the vessels which make up the fleets of Germany and the United States will, however, be carefully considered by those who wish to determine the exact standing of the two fleets.

Total Weight of Metal of Primary Broadside of Capital Ships, January 1st, 1912.

		Weight of Metal of Primary Broadside.		
	No.	German).	No.	United States.
		Lbs.		Lbs.
Battleships (Dreadnought type)	7	44,340	6	50,220
Battleships (pre-Dreadnought)	21	62,540	25	132,435
Battleship Cruisers	2	11,900		
Armored Cruisers	9	15,130	12	25,500
		133,910		208,155

As pointed out in the accompanying article, the weak point in the U. S. Navy is its limited supply of auxiliary ships, the most important of which is the collier.

NAVAL COLLIER COALING THE BATTLESHIP "SOUTH CAROLINA"

The German battleship fleet will, on January 1st, 1912, consist of seven dreadnoughts, twenty-one pre-dreadnoughts and two battleship-cruisers, a total of thirty capital ships, as opposed to thirty-one capital ships in the United States Navy, composed of six dreadnoughts and 25 pre-dreadnoughts, so that numerically, the fleets will be practically equal. When we come, however, to consider the actual fighting value of the units which make up the two fleets we find that, ship for ship, the United States vessels are decidedly superior to those built at a corresponding period in Germany, especially in offensive power.

The ten vessels of the "Kaiser" and "Wittelsbach" types carry a main battery of only four 9.4-inch guns, while the ten following vessels of the "Braunschweig" and "Deutschland" types carry only four 11-inch guns in the main battery, as opposed to these, all the battleships of the United States carry main batteries of four 12-inch, or four 13-inch guns, supplemented in all except the six vessels of the "Maine" and "Illinois" types of intermediate batteries of from four to eight 8-inch guns.

France will have only twenty-one pre-dreadnoughts ready for service on the first of January, 1912, while Japan will have but thirteen, although the latter nation will on that date have two of the battleship-cruiser type.

Of the thirteen battleships which comprise the fleet of Japan, the "Fuji" is practically obsolete; five are reconstructed and repaired vessels captured in the late war and two are coast defense vessel type. The batteries of the two vessels of the "Satsuma" class—4-12 inch and 12-10 inch guns—are so powerful, however, that these vessels should properly be considered dreadnoughts, and the two vessels of the "Kawachi" type carry batteries considerably more powerful than other pre-dreadnoughts of the same period of building.

The comparison, therefore, between these four countries as to their battle fleets, is decidedly in favor of the United States, and it may be contended that so far as the strength of the battleship fleet is concerned that the United States is decidedly superior to that of either France, Germany, Japan, or any other nation.

Considering the geographical and political conditions in the United States, students are pretty generally of the opinion that, in the event of future hostilities between this country and any other nation, the United States will have to carry on an offensive warfare; in other words, will be compelled to take the initiative and to carry on warfare far removed

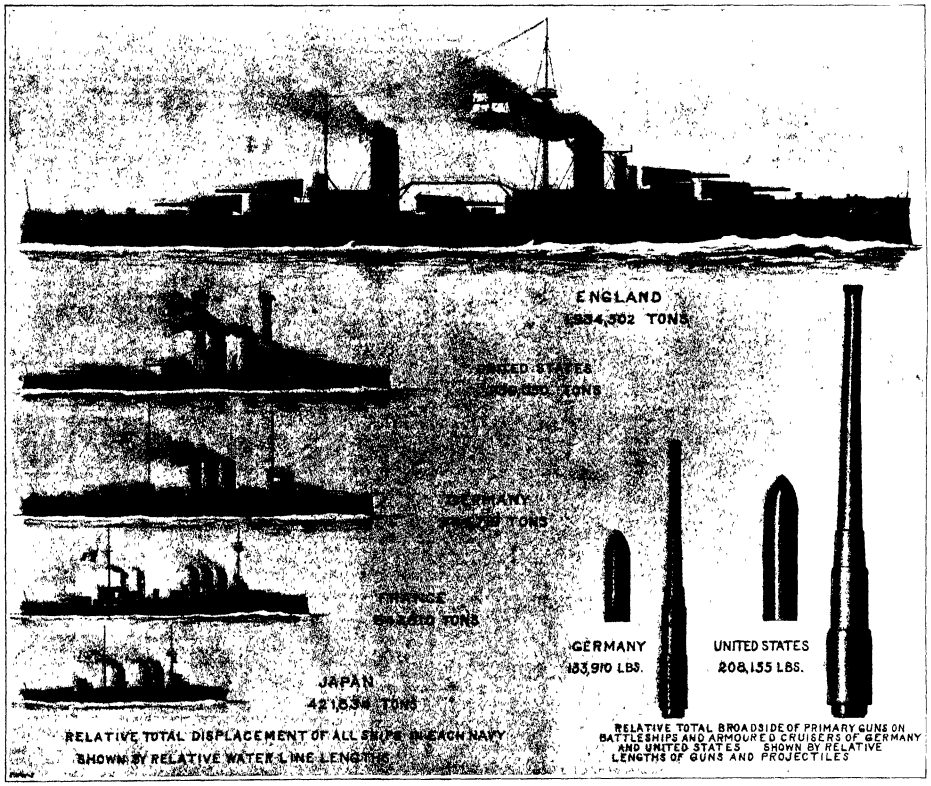
from our coasts or naval bases. This leads up to a consideration of the number and character of the vessels which make up an efficient, well balanced fleet for offensive operations, such as torpedo destroyers, scouts, repair ships, fuel ships, ammunition ships, hospital ships, transports, supply ships and mine-laying vessels—all of which are essential adjuncts of a fleet.

Torpedo Destroyers.

It is considered by students of naval operations that at least four torpedo destroyers are necessary for the defense of each battleship

The rapid development of the automobile torpedo and its increased range render it practically impossible to defend a fleet by means of illumination or the use of searchlights, as the torpedo has now reached a range beyond which, even under the most favorable conditions, the searchlight is of doubtful

Scouts.



The scout is the eye of the fleet, and no matter whether our fleet is operating on the defensive along our own coasts or on the offensive on an enemy's coast, information as to the movement of the enemy is a most important factor in conducting naval operations The scout is in no sense of the word a fighting vessel, and its principal characteristics should be speed, ability to steam at high speed in all weathers and ability to keep the sea for long periods without replenishing its fuel supply

While the introduction of wireless outfits on board modern ships is of the greatest possible value, interference with the successful transmission of a message from a scout to the main body of the fleet is not difficult of accomplishment, and in order to convey important information to the Commander-in-Chief

adequate our merchant ships are for scouting purposes As against the three vessels of this special type, England possesses twenty-three, with nine building, Germany ten, with six building, and Japan four, with three building, therefore, so far as this type of vessel is concerned, the United States Navy is decidedly inferior to those of England, Germany and Japan On the other hand, these three countries possesses in their Merchant Marine a large number of vessels, which in a very short time can be converted into efficient scouts

Fuel and Ammunition.

One of the most important things to be considered in the operations of an offensive fleet is the problem of supplying fuel and ammunition Battleships whose fuel or ammunition supply has been reduced or exhausted cannot be considered very formidable Ar

The greater gun power of the U. S. Navy as compared with that of Germany is due to our pre-dreadnought ships carrying heavier guns in the main batteries Future sea-fights will be fought with dreadnoughts. At the present rate of construction, Germany, in 1917, will possess twice as many dreadnoughts as the United States.

GRAPHIC COMPARISON OF THE RELATIVE STRENGTH OF THE WORLD'S NAVIES

value We must, therefore, depend, for the protection of our battleship fleet, if operating upon an enemy's coast or in proximity to its battleship fleet, upon torpedo destroyers, scouts and other outlying vessels, thrown out as a shield for the protection of the battleships.

An examination of the table shows that on January first, 1912, England will have two hundred and five torpedo destroyers, Germany one hundred and seven, France seventy-two, Japan fifty-nine, while the United States will possess but thirty-six This shows that the United States is woefully deficient in torpedo destroyers, as the estimated number for the protection of a fleet composed of sixteen vessels is sixty-four, and therefore, so far as this element of strength is concerned, the United States ranks below Great Britain, Germany, France and Japan.

of a fleet, it may be necessary for the vessel obtaining such information to communicate with the fleet by visual signals While the scout also forms part of the outposts of a fleet for its defense against surprise and against torpedo attack, its principal function is discovering the whereabouts of the enemy's fleet, keeping in touch with and successfully transmitting information as to its movements—to its own fleet.

The United States Navy possesses but three vessels of this important type, and furthermore, its Merchant Marine does not furnish a single vessel which is in all respects adapted for scouting purposes Few, if any, of our merchant vessels are capable of reaching a speed of more than twenty-one knots, and when it is considered that the modern scout has a speed of at least twenty-six knots, it is clearly seen how in-

rangements must be made for the furnishing of fuel to our battleships at stated intervals either through colliers built for this purpose by the Government or else through vessels bought or chartered for the purpose The United States Navy possesses to-day twenty colliers fit for service, but a large percentage of these vessels has such a small cargo-carrying capacity as to be of little value to the fleet England, Germany and Japan possess few, if any, regular naval colliers, but each of these countries possess a very large Merchant Marine, from which colliers supply vessels and other auxiliaries will be drawn in the event of hostilities We possess no such marine and to-day there are but very few vessels flying the American flag which are at all suitable for naval purposes in any character Unless, therefore, something is done to

(Continued on page 452)

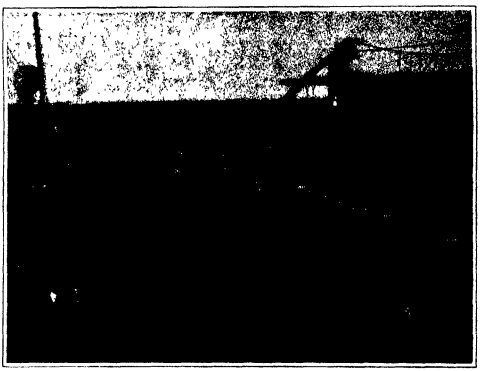
On Board a Battleship

Intimate View of the Life of a Community of One Thousand Souls

By Captain Albert Gleaves, Commanding U. S. Battleship "North Dakota"

LIFE on board ship is but little understood by the general and the ways of the service, if not past finding out, are a closed book to the majority of our fellow citizens. A more intimate contact between the people of the service and commercial people would benefit both with the result that there would be less apprehension for the pocket book when battleships are proposed and less talk of the Angel of Peace hanging his head at the sight of a Building Program. On the contrary, if the Navy and the people knew each other better the "sober citizen" would realize from personal knowledge that he is paying only a trifling insurance on his property for a very real and substantial protection, and the Angel of Peace, instead of protesting would preen his wings for higher flights and chant the ringing notes of an *Io triumphe* as he soared.

Although the Atlantic fleet of twenty to twenty five capital ships and its accompanying auxiliaries, such as colliers, supply and store ships, and repair ships, represent an enormous outlay of public funds the sum is insignificant when compared with the almost fabulous wealth that it protects and the security that it affords. Some one who has a genius for statistics estimates the money value of every enlisted man as $5,000, and places the value of the fleet at 300 millions. If a committee of citizens from all parts of the country could visit the fleet on the Southern Drill Grounds when the ships are cleared for action and just as prepared to engage an enemy as they are to shoot up an irresponsive and insensate target, it would require no argument to prove the need of a navy, nor many arguments to demonstrate the absolute necessity of definite expansion in order to maintain a *vigorous* one. That task, however, is for others. The object of this article is to give some idea to the layman of the *ne intime* on board a battleship in the fleet, how the men live and what they do.



Due to perspective the first view of a battleship may be disappointing. She will probably not appear as big as she has been described, but, once on board, this delusion vanishes. She is a master piece of man's cunning and ingenuity that excites enthusiasm, but she must be studied much and long before she is fully comprehended. Viewed from the taffrail looking forward and upward there is nothing more impressive of the majesty and power of a ship. The eye catches in one glance the armored turrets, the searchlight towers, the broad-bellied funnels, the pendulous cranes and towering above all those prodigies of naval construction the lattice masts—the very latest thing in battleships—called by our sailors "haystacks," and by the English "scrap-baskets."

Each turret with its pair of 12-inch guns weighs about seven hundred tons, but in spite of the inertia of the mass it is so nicely balanced that the guns can be laid to a hairs breadth on the target, and with no more physical effort than is required to turn a wheel of more or less. The guns fire a shell of 870 pounds with a powder charge of 310, and they can be loaded, aimed and fired every thirty seconds, and with such marvelous accuracy and precision, that at a range of five miles they can make twenty per cent of hits on the target, which at that distance appears in the telescope of the gun no bigger than an open umbrella.

A battleship comprises a community of approximately one thousand souls, in which a centralized and autocratic government prevails. The division of labor, exercises and drills, the rules that govern the hours of eating, sleeping and recreation are the last words in routine and organization. Every man has his place and number, and there is not an article on board, from a torpedo to a water breaker that has not its allotted space. Order and system are paramount and the very atmosphere breathes of discipline. At no time is this so apparent as in an emergency, at every signal of danger, whether it be of fire, collision or man overboard, every man instantly jumps to his station, with a perfect knowledge of what is expected of him, but until he gets there, he doesn't know whether it is the real thing or a drill.

The head of this community of sea-people is, of course, the captain. In battle his station is in the conning tower, and under his hand are all the latent Titanic forces of powder, gun-cotton and steam, which may be released only at his bidding. In matters of administration he is judge and jury, and daily at the mast the delinquents are brought before him; he listens to the evidence, and there is no law's delay in his judgments. He messes alone, and his life for the most part is a solitary one. A wise captain will not burden himself unnecessarily; if he would be happy, he must apply to his duties what the Romans used to say of the Praetor, *de minimis non curat*, leaving to others "the mere rude explicit details."

The wardroom mess is presided over by the commander or executive officer, and is composed of the staff officers and the lieutenants. And merry times they have when the rigid discipline of the day's work gives place to post-prandial relaxation of the evening. Then there are the junior officers' mess composed of midshipmen, and also the mess composed of warrant officers, those men of the rank and file who by faithful service have become gunners, boatswains and machinists. Cheeks and Chips as described by Marryat are as dead as Henry IV. The old stories of the wind jammers have passed into oblivion, and the service to-day is unconsciously working out new traditions that will be handed down to the coming generation of sea folk.

Of this most effective corps, each battleship carries two officers and sixty to seventy men.

THE MARINES

Forward of the mast there is a big household, which requires $75,000 per month to care for clothes and feed in their ten-million-dollar home. Nearly all trades are represented in this little kingdom of the sea. Tailors, shoemakers, photographers, jewelers, barbers, and musicians, for the most part a man is allowed to ply his trade so long as there is no interference with his military duties. Regular prices are established by the captain, and as there is no competition, each has a large *clientele*. The galleys have the best possible system of cooking, supplemented with electric potato peelers, electric meat choppers and electric dish washers. The bakery provides bread at all times instead of hard-tack, which was formerly supplied, and furnishes seven hundred loaves daily; there is a laundry, which has a fine equipment of machines run by electricity, and is handled by sailors who are excused from all other work except battle and fire stations, a cold storage with a capacity for provisions for one month for the entire ship's company, and a hospital or sick-bay, well lighted and well ventilated, which is located in a comfortable part of the ship. The hospital contains a sick ward proper with bunks for a score of patients, the isolation ward and the operating room. The last is fitted with every convenience known to modern practice, including an adjustable operating table and a sterilizing plant. Every battleship has a branch post-office in charge of sailors appointed by the captain, which is under the same postal regulations that govern the shore stations. A complete telephone system connects all parts of the ship, and is supplemented by voice pipe communication, which is used principally in action. There is also a wireless installation, and officers as well as the operators are encouraged to become proficient in its use.

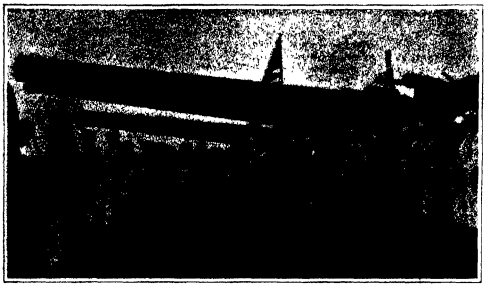
Those who are concerned especially for the moral welfare of the men will be interested in the "brig" as sailors call the prison, and they will perhaps be surprised at the spacious, not to say comfortable *points d'arret* of those who violate the Articles for the Better Government of the Navy. Down below the gun deck are the berth deck spaces, and still farther below are innumerable storerooms, the magazines and torpedo room, ammunition passages and dynamo rooms.

The pay of the men varies from twenty to one hundred and fifteen dollars per month, depending upon the rate, length of service and conduct. Those who wish to save their money may deposit it in the bank with the paymaster, and the government pays four per cent interest. As the term of enlistment is for four years, it is not difficult for a man to save as much as fifty or sixty per cent of his pay during his cruise.

On Sundays after inspection, the bugler sounds the church call, and the church pennant, a blue cross on a white triangle, is hoisted *above* the national colors. Attendance at church is of course not compulsory, but in the words of the Articles of War, "it is earnestly recommended to all officers, seamen and others in the naval service diligently to attend at every performance of the worship of Almighty God." The altar is rigged below decks, and apprentices selected from the Catholic lads act as acolytes, the priest in his vestments conducts the services with all the rites of bell, book and candle, as if on shore. A large percentage of the crew are usually Roman Catholics, and so the temporary church is always crowded.

Of course the whole idea of a ship and its reason for being is to fight, and until a captain can feel that his ship is ready at all times for battle, his task remains incomplete. The nearest approach to action at present is the semi-annual target practice, and the rivalries of the Derby and the Ascot are as nothing compared with the competition between ships for the coveted gunnery pennant and the bronze trophy, that Ark of the Covenant which is the final *cachet* of efficiency and achievement. During the period of preparation immediately preceding the practice, when "days are full of labor and nights devoid of ease," and everybody is under a strain like that of the first public speech, one hears nothing in the mess rooms and about the decks but discussion and arguments relating to "hits per gun per minute," this or that system of fire-control, and the latest suggestions for "plotting and tracking." The ships lose their smart appearance, for there is no time for the paint brush and the holy-stone; men and officers are rarely out of dungarees, they live in the turrets, working day and night to perfect the adjustment of every detail of the mechanism for loading, training and firing. When the day arrives for which the months before have been a training, the ship is cleared for action, and stripped of all superfluous articles until she looks as sleek as a race horse clean groomed from the paddock. The scheme, generally speaking, is this: The ship steams to the firing line far away from the target, then rounds to, and makes the "approach" at full speed. When she comes within range, fire is opened at the target, which looks like a blur in the haze. *It* a division of four ships are engaging a string of targets towed in tandem, it is a sight never to be forgotten. Broadside follows broadside with astonishing rapidity; the thunder of the guns is deafening and would be absolutely destructive to the ear drums, were it not for ear protectors. The people in the turrets and in the conning tower experience no inconvenience from

its cause, but out on the deck in the open, the shock is tremendous, so much so that a broadside of ten guns heels a 20,000-ton ship four degrees. When the firing begins, hot blasts from the guns flick the air, in flame-slitted reddish brown smoke spurts in thick clouds from their "rude throats," but dissipates almost instantly, and the air is filled with the pungent odors of burnt gases. The spotters aloft watch anxiously for the geyser-like splashes, that show where the shot struck, and the sight-bar ranges are quickly changed until the gun-pointers are "on."



There are other drills and many of them; abandon ship, fire, and collision, signals and boats, and in addition there is the never-ending work of the care and upkeep of the ship, which must go on constantly.

But besides being sailormen by profession, the bluejackets are given something more than an elementary instruction in soldiering; they drill as companies, regiments and brigades; they make practice marches, and when occasion offers they go into camp as at Guantanamo.

But it is not all work on board ships; there is some beer and skittles. The routine keeps every one busy pretty much all the time, still there are intervals between drills, and on certain afternoons, when there are no drills at all and the men may smoke and mend their clothes, or get down to their ditty boxes, and spend an hour or so with old letters and photographs. Smokers are a feature of life on board, and there is nothing like the quarter deck of a battleship for the *mise en scene* of a wrestling bout, a boxing match, a song and dance, juggling, slack wire performance, or any other stunts for which there is ample talent in a crew of one thousand men. Then the tops of the turrets are crowded with the bleachers, and officers and crew gather together around the improvised ring. Usually the athletic officer or the chaplain is the master of the revels. It is astonishing how much genuine talent is found in a ship's company, and the artists are always ready to contribute to the entertainment of their shipmates.

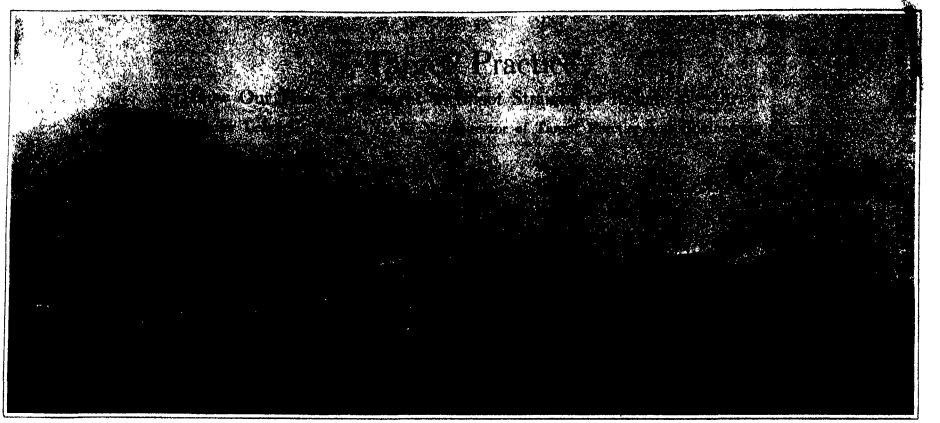
In the evening after supper when the band plays, the men dance and sing or gather around the turrets and "gam" until nine o'clock, when it is pipe down and all hands must turn in. Sometimes there are moving picture shows on the quarter deck, the films are all carefully selected, and as each ship passes here to the next, there is a great variety in the fleet. Those of dramatic and romantic character are the most popular, and always draw rounds of applause. Recently on one ship, when thirty miles at sea, butterflies blown off by the land breeze had fluttered around the ridge-ropes and life-lines all day; but the finishing home touch was given at night, during one of the moving picture shows, by the chirping of a cricket hidden somewhere in the cork fenders.

Very little of the old navy is left in the new, either in equipment, manners or customs. There is even a new terminology. The bow-legged type of sailor with coppery nose, groggy eyes and a collar of whiskers around his face, survives only in the penny-dreadfuls and comic operas. He has given place to bright-eyed lads, lean in the flank, well groomed, quick and ready to meet any emergency. It is worth noting that the average age of the ship's company is less than 25 years. The man-of-war's man of to-day is a self-respecting, intelligent citizen (only about four per cent are aliens) who reflects credit on the flag wherever he may go. In the cruise of the Atlantic fleet to Europe last winter, 12,000 men visited London and Paris, and there were only a few instances of serious misconduct, and although leave was granted to visit Norway, Sweden, Germany and Ireland, there was no instance where they did not return to their ships, and for the most part on time. The appearance of our men drew forth from an English writer a shrieking article commenting on their lankness, lack of physique, and, tell it not in Gath, in some special cases their kid gloves and eye glasses. A French artist in Paris was not more complimentary in his cartoons. However, it is good to see ourselves as others see us, and as we are not responsible for foreign spectacles we may afford to be amused. There is another point. The Honorable Herbert Satterlee recently referred to the United States Navy as the Great American University. The comparison is apt and just. It is a university whose students number 48,000 youths and men from all parts of the country. This ocean university costs the Government 140 millions annually, but in it is taught that which above all things is the corner stone of every great nation, respect and obedience to constituted authority. The hundreds of sailors who yearly leave the navy with honorable discharges, and go out in every day life become, it may be unconsciously, missionaries for the service. They return to their people with the story of those who live between sea and cloud, who pursue their occasions on the sea in craft as different from the ships of yesterday as the ark differed from the Navy of Tarshish. In time their knowledge of the service will spread, and gradually the people will come to have as much pride in their navy as the British people have in theirs, and when that time comes there will be no fear or apprehension as to our future security on the seas. For those who believe that the navy as it is to-day, is all that the nation requires, it will be well to recall what Emerson said of our civilization. "We think it near its meridian, but we are yet only at the cock-crowing and the morning star."

The complement of our latest battleships is one thousand officers and men of whom the greater part are seamen.

THE SEAMEN

Copyright 1911 by Clarke & Muller.



This remarkable photograph, taken from the bow of the "Connecticut," shows only one-third of the total complement of 980 officers and men. Admiral Osterhaus, commander-in-chief of the Atlantic fleet, is the central figure in the second line.

ON THE FO'CAS'LE DECK OF THE U. S. FLAGSHIP "CONNECTICUT"

The Cooling of Ammunition Rooms

THE unparalelled catastrophe by which the French battleship "Liberte" was sunk has brought the question of the temperature of the ammunition rooms once more into prominence. The report of Vice Admiral Bellue upon the temperature of the ammunition rooms of the battleship "Jules Michelet" during the period from April to October has now been published. The Minister of the Navy considers that the temperature of 30 deg Cent at which the powder remained in some of the rooms is altogether too high. The temperature is now to be kept below 25 deg. Cent. Upon some of the battleships such as the "Danton" and "Voltaire," the Leblanc refrigerating system, which was installed, has been giving very good results.

In view of the tragic results which may follow from the deterioration of modern smokeless powders, it is gratifying to remember that our own naval powder has shown a marked stability, and that our own methods of cooling and ventilating the ammunition rooms are giving satisfaction.

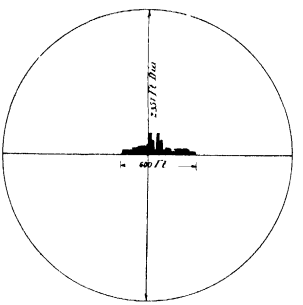
HEAVY WEATHER IN THE NORTH ATLANTIC

A SAILOR'S preparation for battle begins the moment he comes aboard ship. Within half an hour of his arrival, he has been given a station at a gun with some of the oldest sailors to instruct him in his duties. The new recruit is first tried at aiming drill with a rifle, to see if there are any personal errors that are likely to disqualify him from the start. If he passes this preliminary step he is taken immediately to the mechanical instruments, "dotter" and "Morris tube," and is directed to aim at a stationary target. An officer supervises this exercise, and after two or three days' work at a stationary target, the recruit is exercised at a moving target so as to develop his skill in controlling the electrical elevating and training gear in any kind of a seaway that may be encountered in "action." He actually operates the elevating and training gear of the gun he will handle in battle so that his education is practical from the start.



It is easy enough to develop gun pointers to fire from a stationary platform, or to fire in smooth water from a ship under way. As soon as the elements of roll and pitch are brought in, however, an entirely different kind of training is necessary, and it is found that a man who is expert in smooth water may be of no use whatever when firing from a platform, whose motion is as irregular as that of a ship in a moderate sea.

In order that no time may be lost by training gun pointers under smooth water conditions, the motion of the mechanical "dotter" is made to simulate, as nearly as possible the motion of the ship in a seaway, so that the man may not be deprived of this training, should the ship be alongside the dock or in a navy yard for urgent repairs.

The "dotter" is an electrically controlled instrument, so constructed that the target, a miniature ship will have the same motion with reference to the pointer's eye as an enemy's ship would have if viewed from one of our vessels, steaming at high speed in a heavy sea. When the cross wires of the pointer's telescope are exactly on the center of the target the gun-firing key should be pressed causing an electrically operated pencil to make a dot on the target sheet. The target being in motion both vertically and horizontally the pointer's skill is gaged by the rapidity and accuracy with which he places his "dots" when aiming at the center of the target. The "Morris tube" is a somewhat similar instrument with the exception that a small rifle attached to the heavy gun is fired electrically and sends its bullet through the target sheet.

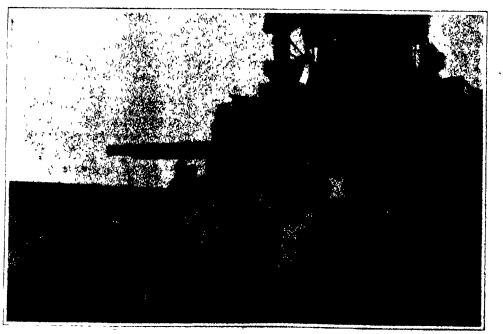
The Navy Department has issued a general order that gun-pointers shall be trained throughout the year several times each week, so that no matter on what duty engaged or in what country the ship may be, guns' crews will be in such efficient condition that they can engage in action at a moment's notice. This order has had a very far reaching effect, for it keeps the whole personnel and material of the ships up to the highest standard of efficiency at all times.

When the gun-pointers have been trained so that they can follow a rapidly-moving target and make hits with great skill, they are taught to fire on signal,

Appearance of battleship at 10,000 yards, as seen through gun-sight telescope.

so that whole broadsides may be fired at the same instant. This requires unusual concentration on their part and a most intimate knowledge of the electrical gear by which the guns are controlled. The pointers are required to fire within a second after the firing signal is given, and when it is remembered that they operate the controlling levers of the enormous 60-ton guns and of the turrets of 500 tons weight each, making them follow the peculiar and mystifying roll and pitch of the ship it can well be seen that constant training and wonderful skill are necessary.

During all the above mentioned training the other members of the guns' crews, the sight-setters who mark the range given by the fire control officers, the men who open the breech-plugs, the men who put in the powder, and the men who hoist and ram home the projectiles are all being daily and competitively trained.



It is this feature of competition that has had most to do with the remarkable development of gunnery in the Navy, for every officer and man is in competition with every other, and at the completion of the target practice or at the end of the year's gunnery work, they receive their rewards in trophies, letters of commendation, and gunnery "E's," which last may be worn only by men of winning gun or turret crews as a special mark of efficiency.

No detail of the training is too small to be given the undivided attention of the officer in charge. The apparently simple motion of setting the sights for each new range has to be watched from day to day, by giving numerous sets of ranges to several men in competition, and noting the rapidity and accuracy with which each accomplishes the work assigned him.

The men who open the heavy breech-plugs, one-half ton in weight, do so wholly by hand-power, as it is found to be as rapid and more reliable than any mechanical means. Even in this particular work the men are placed in competition, for the officer stands by with his stopwatch and starts two plugmen at the same instant withdrawing their plugs, noting the time when each has completed his work. With skilled plugmen this varies from 2 2/5 seconds to 3 seconds for 12-inch guns, and the slower plugmen are given other work requiring less speed and strength.

Every step of the drill is carefully worked out before any two steps are combined. All the men are tried out to see which ones will make the best powder passers, and as this is very trying work during a protracted engagement, only the strongest and most active men are selected for this duty.

The men who ram home the enormous projectiles, weighing 870 pounds, require a great deal of drill, for a slight error of a fifth of a second in applying the necessary force to seat them may well cause

This crew in No. 3 turret made the highest score on Southern Drill Grounds in the spring battle practice in 1911.

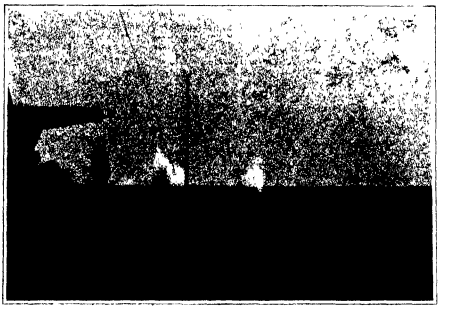
PRIZE WINNING CREW OF U. S. S. "MICHIGAN"

the loss of 3 or 4 seconds in the complete load As it is necessary to deliver the greatest number of hits in the shortest possible time after the enemy is sighted, it will be seen how vital it is that not a fraction of a second should be lost in any of the details of loading or firing. It may well happen in a naval duel between two battleships that one of them will be put out of action within five minutes after the first shot is fired

Although to the casual observer of the daily competitive drills there appears only the keen sportsman's instinct to win, there is also a grim feeling that some day the national honor may depend upon the saving of a few seconds, enabling us to deliver a broadside of highly destructive projectiles into the vital parts of an enemy at a critical moment

The character of the enlisted force of the service has changed remarkably in the last 15 years There is a community of interest between the officers and men The reasons for every order are fully explained, so that the men are thoroughly familiar with the object sought and with the material used. This applies not only to loading and firing the guns but to the whole fire-control and range-finding system, so that when a naval battle is fought, intelligent petty officers may take the place of officers who are killed or disabled The whole service is working together with one end in view, that of efficiency in battle

A recent order of the Navy Department calls for carrying out the drills with guns and fire-control parties during rain, snow and heavy weather generally, so that our men may be prepared for the most adverse weather conditions to be encountered "in action" Crews drilled in smooth water only and in fair weather are worthless when firing in rough weather in the open seas



After the training with the mechanical targets on board ship is completed and after the loading crews are well instructed, a certain amount of ammunition is provided to fire the guns under the same conditions as would obtain 'in action," so that the officers may find out definitely whether or not any particular pointer is "gun shy" During this practice a target is used on which the hits are recorded, or photographic records are kept, so that the final efficiency of the gun-pointer is obtained while the guns are actually firing Should a pointer show any evidence of being "gun shy," he is immediately dismissed from the gun crew The training from now on is a co-ordination of all the units, that is of all the gun crews and fire-control parties, so that when the day comes for the final test of the ship at battle practice in heavy weather, the team work will show how faithfully the individual operations have been performed

At battle practice the conditions are made just as severe as those that would obtain in actual "action" The firing vessel has no knowledge of the course, speed, or distance of the target vessel All the information she has is that somewhere on the horizon at a distance of 10 miles or more is a column of smoke which marks the enemy at which she is to shoot She steams toward it at her best speed and opens fire at whatever range she chooses, but the value of hitting at long ranges is vitally impressed on her by the amount which is added to or subtracted from her score for the shots that hit beyond 12,000 yards or under that mark The whole firing is finished in four minutes and she has no other chance to make good if she has failed in this No excuses are accepted for failure of guns to fire, for breaking down of any gear or for any faults of the personnel or material The instant the target is sighted, the firing vessel must steam toward it at high speed and deliver her salvos in the shortest possible time

Part of the most important training is that given to the "spotters" both officers and men These are detailed in accordance with their skill at estimating distances at which the projectiles fall short or over the target at ranges of from 10,000 to 13,000 yards in the open sea They must show a very high degree of skill, for on their accurate judgment and their cool heads during battle, depend the life of the Fleet and of the Nation They are trained daily at "spotting boards," and at these drills the most skillful are selected to be further trained at the spotting practices where actual projectiles are used against an armored target At the recent spotting practice against the "San Marcos" in Chesapeake Bay it was found that salvos of eight projectiles fired at a distance of 11,500 yards could be placed on any part of the target ship

Though the gun pointers and the gun crews are perfect, their skill is of little value if the fire-control parties are not sufficiently well trained to estimate the proper errors in range and bring the center of impact of all projectiles on the target The demonstration against the "San Marcos" (ex "Texas") was one of the most remarkable exhibitions of team work ever shown in the Navy The theoretical number of possible hits at that range, if all conditions of temperature, atmosphere steadiness of platform, skill of gun pointers, etc., were perfect, was 45 per cent The detailed examination made by the special board showed definite evidence of 43 per cent of hits, the board further stating that so much of the ship was shot away, it might well be that many other projectiles hit the "San Marcos" without leaving a definite record

The prizes for gunnery work on elementary practice are of little value and in the annual battle practice each year, where the keenest interest is displayed by every officer and man in the fleet the only reward is a little piece of red bunting with a black ball in the center, floating proudly at the mast head of the winning ship

FORWARD TURRET OF THE U. S. BATTLESHIP "MINNESOTA"

A Landsman's Log Aboard the Battleship "North Dakota"—V.

"The Greatest Game in the World"

By J. Bernard Walker, Editor of the SCIENTIFIC AMERICAN

"And there, glasses on the target, his mouth at the telephone, is the man upon whom, more than any other, depend the fortunes of the day—the spotter. A natural aptitude and long experience enable him to judge with marvelous accuracy by how much the splashes of the shells are short or over, to right or to left of, the target."

"TELL you sir, it's the greatest game in the world" We were in the fore top of the 'North Dakota' which, having just completed the autumn practice with her 12 inch guns, was steaming in to take a look at the target The other occupants of the platform had disappeared through the trap door in the floor and only the Lieutenant who had done the spotting and I were left 'A great game, but dangerous, I suggested, 'no protection, ricochet shots, high explosive shells—these masts, if the enemy can shoot like the 'North Dakota' must come down early in the action" The officer was removing his telephone headpiece, he stopped, turned, and quick as a flash came the response 'Then it's the grandest way to die'" and as he climbed down the chain ladder, leaving me alone, the words of the old Roman passed through my mind Dulce et decorum est pro patria mori' (Sweet it is and altogether fitting to die for one's native land)

"Yes" I thought 'there is the whole story The greatest game—the grandest death—an epitome of the fine spirit of our navy'

How has it come about that this target practice, once a drudgery (I had almost said a joke), has become to the officers and men of our navy "the greatest game in the world"—great in the excitement and keen competition of the preliminary training, and great in all that it stands for as the final arbiter when peaceful means have failed, of the fate of a nation?

If the reader of this log would know, let him fellow me, this fine October morning as I squeeze through a door in the overhanging floor of No 3 turret, and then scramble down as best I may, until I stand on the double bottom of the ship 23 feet below the surface of the water and some 56 feet below the pair of 12 inch guns Here I find myself in a compartment 20 feet square Rising from its center is the base of the rotating turret structure attached to which, and turning with it, are two elevators or "hoists," whose shell and powder cars stand ready for loading Water tight doors lead from this handling room into several surrounding compartments At the invitation of the ensign who has charge of the crew I enter one of these compartments the shell room Here I see two after tier of the huge, 12-inch 870-pound shells resting in strong steel racks Overhead and leading out to the ammunition hoist is a trolley rail, carrying a traveling chain hoist Returning to the handling room, I enter another compartment in which, neatly stored in racks, are the powder charges each sewed up in a silk bag and inclosed in a copper case The walls of these compartments are heavily lined with asbestos, and refrigerated air circulates throughout them maintaining the ammunition at a constant, predetermined temperature

I am down here to witness the drill with dummy shells and dummy bags of powder of the same size and weight as the service shells and powder which for weeks past has been carried out daily as part of the ship's routine A dozen or fifteen men stand at their stations The shell-room door is open; within it the chain hoist hangs ready for service The powder-room door is shut, it has a circular opening, large enough for the passage of a bag of powder, which is closed by a hinged brass flap—this to prevent any accidental spark or fire from passing to the magazine

The ensign borrows my watch 'Load'" A shell is gripped and hoisted from the rack—three men push it, on the run, to the hoist—a catch is released, and the 870-pound mass drops with a crash into the car' Meanwhile three men grab, in succession three bags of powder, as they are thrust through the flap-covered hole in the powder room door, run with them to the hoist and drop them into the car, which, with a whirr, swoops up in a swift dash to the guns above

"Rotten'" shouts the ensign, "lads this will never do, you took 15 seconds, try it again" Down comes the car and the dummies are returned to their racks Some changes are made in the stations of the men "Load'" Another wild rush, in which a powder-bag man over-runs himself and sprawls, hugging his bag, causing the loss of a precious moment "Twelve seconds' that is better, but you won't beat the 'Delaware' at this gait Try again" Once more I see these eager young men (they are green hands—not many months ago they were at work on farm and in factory) standing tip-toe with eager excitement "Load'"—"Ten seconds' Bully, lads—that will do"

A day or two later, by the courtesy of the turret officer, I stood within this same turret during the firing with full service charges, on the target practice run My position was against the rear wall, immediately back of the right-hand gun To the right of the gun, at the front of the turret and immediately back of the sloping port-plate, 12 inches thick, stood the gun-pointer, his eye at the eye piece of a periscope, whose object glass was outside the turret in a little armored hood on the side wall The pointer's left hand was on a trigger If that missed fire, there was another close beside it Should that also fail, a foot-pedal would do the trick His work was to keep the horizontal wire on the target This he did by a lever in his right hand, which operated a powerful and wonderfully sensitive differential oil motor of variable speed Under his hand the muzzle of the gun rose and fell as though it were a shoulder piece instead of a 50-ton mass of metal The turret (and therefore the guns) was moved to right or left (trained) by a man whose position was between the two guns. He also was immediately behind the port-plate He grasped a wheel (much like an auto's steering wheel), and by a differential-gear motor moved the huge mass of the turret and guns, weighing several hundred tons, as swiftly and lightly as though it were a one-pounder. He also saw the mark through a periscope, and he steadily kept the vertical wire of his telescope on the center of the target

Back of our gun-pointer stood the sight-setter, telephone clamped over his ears To him, from the central station below the protective deck, came the "range" (elevation) and the "deflection" (corrections for speed of enemy, wind, side drift of shell due to its rotation, etc.). His duty was to turn a disk till the pointer stood at the range as announced to him; and to turn, also, a little cylinder, until it registered the proper deflection.

Back of the sight-setter was a lusty and powerfully-muscled young seaman, who grasped the handle of a crank, by which, through a worm gear, the massive breech-block was opened and shut Next to him was the primer man, with his rows of primers standing conveniently to hand in a case on the turret wall Immediately back of the breech-block was the turret captain To the rear of him sitting on one of a row of 12-inch shells, with his back against the rear turret wall, was I, gathering material for this log To my left was a junior lieutenant, in charge of the crew When I had last seen him he was in his immaculate whites and shoulder straps—now he was in dungaree trousers and a sleeveless undershirt To his left, in line with the bore of the gun, was the electric rammer To the left of the rammer was a man grasping the control of the electric motor that drives the rammer Ahead of him was another man, with his hand on the control of the ammunition hoist

A steel bulkhead separated the two guns and their crews, placed there so that an accident or a bursting shell in one compartment would not "rattle" the crew in the other In the extreme rear of the turret communicating through a small shutter in the door that led to each gun compartment, was a little room (booth) in which was seated the turret officer, a senior lieutenant He was in telephonic communication with the fire control officer (the executive officer in the conning tower, who under the captain, fights the ship) In front of him were some electric switches and cut-outs (normally open) which the turret officer closes on notification to be ready to fire Until he closes them the guns cannot be fired

We are now on the range The command is given to load. The young Hercules whirls his crank—the breech block opens—with a rush the ammunition car comes up from below, stopping with the shell opposite the open breech—the rammer jumps forward, thrusting home and seating the shell—the rammer returns—a bag of powder falls from the car in front of the rammer and is thrust into the open maw of the gun—then another, and yet a third—340 pounds in all Our young Hercules whirls his crank—again the massive breech-block swings into place, and all is ready for the 'buzzer," sounded from the conning tower, at whose notification the gun-pointer will send the shell on its long flight to the mark

Suddenly there came a clash and jar of the turret, not unlike the noise and shock when a train backs up rather briskly to couple up the railroad car in which one is riding; and the huge bulk of the gun jumps back some three feet, and instantly returns with a crash into battery (its normal position), the recoil occupying but a fraction of a second Then follows a blast of air—the compressed air-blast blowing the gases out of the gun—and the breech is open for the next loading.

Thus, with clock-like regularity we fired—six times in swift succession—and the run was over. At point-blank range, with no delay in waiting for the spotter's corrections, these 12-inch guns can be fired three times a minute.

I heard very little of the report of the guns—I was to hear that from the fire-control platform on the next run Outside of the railroad-coupling shock and the swift recoil and return of the gun, there was nothing to tell me that, at each discharge, 50,000 foot-tons of energy had been let loose within a few feet of me—enough to lift that gun 1,000 feet into the air!

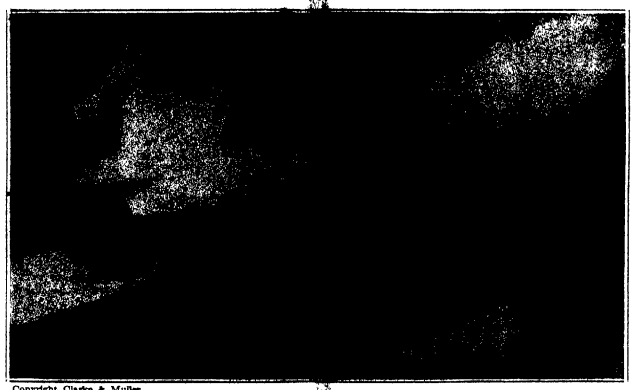
Then I left the turret, went forward and climbed the chain ladder that zig-zags inside the forward cage mast and lets you through a trap door onto the fire control platform Just here, in passing, let me tell you, fellow landsmen that if you wish for a really novel sensation in climbing, you can get it when swinging 100 feet in mid air from an abominably flexible chain ladder, from which you look down into the black hell mouth of a smokestack that is doing its best to destroy your fast-expiring sense of balance by belching at you large volumes of hot furnace gas

But, once arrived at the coveted perch—what a spectacle! Below is the good ship 'North Dakota,' her deck turrets and guns seen in plan, and looking curiously like those line-cut deck plans of Uncle Sam's ships which you and I have seen at times on the pages of the SCIENTIFIC AMERICAN All around and gently convexing to the far horizon, is the sea—"calm as" the proverbial "mill pond"—reflecting in deeper tone the glorious blue of the cloudless heavens And there some seven miles away, is the target—a tiny dull-gray patch, doing its 10 knots some 350 yards astern of the towing ship

The platform is roomy, eight by twelve feet, I judge What I see is typical of what I saw on other ships Here, an officer is telephoning the compass readings to the fire control station below decks Another stands at the range-finder and calls into his mouthpiece the automatically recorded distances to the target A seaman at a kind of typewriter arrangement presses buttons, which serve to display the range in big numbers on the under side of the platform

Here stand the umpires from other ships, and there, glasses on the target, his mouth at the telephone, is the man upon whom, more than any other, depend the fortunes of the day—the spotter A natural aptitude and long experience enable him to judge with marvelous accuracy by how much the splashes of the shells are short or over, to right or to left of the target

The speed is raised to 15 knots we are closing in to the minimum range, for reduced charges, 9,000 yards We may go closer than that, but if we do the results will be penalized In monotonous tone the ranges are called off, 11,000 yards, 10,000, 9,700, 9,200 and then 9,000 I look over the breast high rail at the guns, when suddenly there comes the flash of the first ranging shot Fifteen seconds or so later there is a splash at the target, which, to my unaccustomed eyes, appears to be but a few feet in front of it and, surely, at its very center I am wrong, for I hear the spotter call into his mouthpiece "Two hundred up—two left," which means that the shot has dropped 200 yards this side of the target and two "knots" or say about 40 feet to the right of the mark



Down to the central station and thence to the gun, go the corrections Mentally I can see the sight-setter adding 200 yards to the elevation and 40 feet to the deflection But there goes another gun followed by another cry of the shell, and another splash, this time beyond the

(Concluded on page 532)

"Later, a four-gun salvo went clean through the target, tearing a large part of it away and throwing up the characteristic pale columns of water just beyond."

Copyright Clarke & Muller

"The plate herewith shown bears dramatic evidence of the power of the mighty gun blast. The photographer had the temerity to stand on the forward bridge of the 'Michigan,' to take a four-gun salvo. After the discharge, he lay on his back, his camera smashed, but his picture saved, except for the diagonal crack, which is visible on the plate, running from left to right - mute evidence of the mishap."

Copyright Clarke & Muller.

"Later in the day the wet screen which covered the target was brought on board, where it was carefully combed over by the umpires, the ordnance-officer, and the spotter, who searched every square foot of it, looking for the coveted ragged hole, with as much care as a prospector looked for a color of gold in his pan."

"Here, an officer is telephoning the compass readings to the fire-control station below decks Another stands at the range-finder and calls into his mouthpiece the automatically-recorded distances to the target. A seaman at a kind of typewriter arrangement presses buttons, which serve to display the range in big numbers on the under side of the platform."

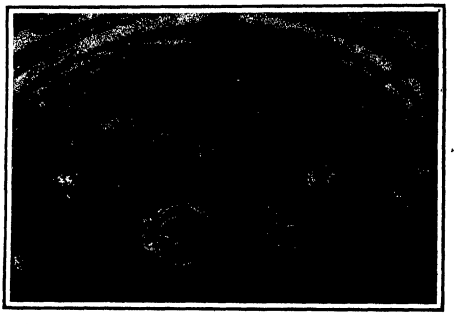
The Modern Submarine

A Seaworthy and Deadly Craft, Which May Ultimately Dominate Naval Warfare

By Lieut. D. C. Bingham, Assistant Director of Target Practice, Etc., Late Commander Third Submarine Division

THE influence of sea power on the rise and fall of governments is well understood. In the most sea power has been won and held by vessels that cruised and fought on the surface of the seas, and the logical outcome is the enormous displacements of the fighting ships of all countries. Within the last decade three weapons of warfare, which in future struggles for the control of the seas are to be of great importance, have been undergoing development. These three weapons are the automobile torpedo, the submarine and aero-craft. Too much stress cannot be laid on their influence on sea power; the submarine carrying the automobile torpedo as the destructive agency, the aero-craft acting as a scout.

A number of erroneous ideas exist in regard to the modern submarine, which prevent a thorough understanding of that type of vessel—its achievements and its future development. A few of the causes and conditions producing the above result will be dealt with briefly.



The policy of secrecy that has been maintained in the development of the submarine has led to its being looked upon as something mysterious. So long as the popular idea of a submarine is one of mystery, just so long will it fail to receive the recognition it deserves. Many unreasonable claims are made for new inventions, even those barely out of the experimental stage, and the submarine has not escaped, although now it has passed beyond the experimental stage, a fact which the progressive programmes of construction, especially in Great Britain, prove most conclusively.

Those who do not know the submarine quickly bring to your attention certain dangers to which it is exposed, that are supposed to make it as much of a menace to itself as to other vessels. These dangers are generally grouped under the head of "explosions" and "collisions." A few moments' reflection will reveal the fact that these risks are not peculiar to the submarine, except in the case of a collision when the submarine is rising from a complete submergence. These dangers are avoided by submarines in the same way as by surface vessels, although there is more care exercised aboard the submarine than on any other type of vessel. The danger of explosion lies in the storage battery and the fuel oil, which are the sources of power respectively for submerged and surface cruising. Thousands of power boats, automobiles, etc., use gasoline without fear, and the same is true of the storage battery except as to numbers. The danger of collision is no greater for the submarine than for surface craft, except in the case when the submarine is changing its depth from sixty feet or more to one of about twenty. At sixty feet the submarine is clear of the hulls of shipping, at twenty the shipping can be observed through the observation tubes, or periscopes. The time to rise from sixty feet to twenty is but a few seconds, and before the ascent is made it is the practice to carefully "listen in" on the submarine bell receivers for the noises made by the propellers of passing vessels, and a submarine commander is almost assured that no danger lies above before changing depth. Even the danger from collision is not so great as is generally supposed. The submarine may be divided into compartments, any one of which may be flooded without destroying the flotation, furthermore, being built to run under the surface, it is stronger in construction than those vessels designed solely for surface cruising.

The phrase, "The Mother and her Chicks alongside," which often appears in the press cannot fail to leave an impression of weakness and helplessness. The battleship divisions of the Atlantic fleet to-day do not assemble without their repair ships, supply ships, colliers, tugs, and tenders, all of which are "Mothers," and as an effective force they cannot move away from the coast without them.

Diving to avoid collision has its share in building up the mysterious atmosphere about the submarine. It sounds well as a subject of conversation and gives a thrilling touch to a story, nevertheless few submarine commanders ever consider that method of avoiding imminent collision.

During the last half century the advance in hull construction and in propelling machinery has made of the submarine a vessel that can cruise and maneuver on the surface, that can change its depth of submergence with safety and rapidity, and that can readily maneuver submerged. Its tanks, to which water is admitted when a submergence is made, are constructed to withstand the pressure due to a depth of two hundred feet, and they are fitted with simple and quick means of admitting and discharging the water. Air pressure and large pumps driven by electricity are generally used when it is desired to free the tanks of water. Compressed air is carried in strongly constructed tanks for expelling water from the tanks and for renewing the air in the vessel during a submergence, although air renewal is not necessary for runs of under three or four hours' duration. The motive power on the surface is the fuel oil engine, under the surface it is the electric motor driven by the power of the storage batteries. In making passage from one point to another the modern submarine uses the same methods appliances, landmarks, etc., as surface vessels. When cruising submerged with the tops of the periscopes exposed, the methods, etc., are the same, except that the bearings and observations are taken through the periscope, and when totally submerged the conditions as regards vision are the same as those aboard a surface vessel cruising in a fog, as it is impossible to see more than a few feet through the waters of the sea. The depth under water is registered on a number of water-pressure gages, and there is never any doubt as to the distance of the vessel from the surface.

In the center are the two torpedo discharge tubes. To the left is the electric motor and gear by which the doors in the nose of the submarine are opened for discharge of torpedoes.

INTERIOR VIEW ON MAIN FLOOR OF SUBMARINE "NARWHAL"

View looking forward from the bridge, showing the ample deck space.

THE SUBMARINE "NARWHAL" MAKING 14 KNOTS AT THE SURFACE

The operation of making a submergence in the modern submarine is comparatively simple and is readily understood. First, the upper deck is cleared of bridges, life lines, etc., although in time of war and maneuvers this gear is not rigged. This material is stowed inside of the submarine and can be unrigged within eight minutes. Second, the vessel is completely sealed; an operation that requires only a few seconds. The large holes in the hull are covered by doors with rubber fittings and are made watertight by the throw of a lever, the smaller holes are closed by a turn of a valve handle. Third, water is first admitted to one or more large tanks to destroy the major part of the floating power of the vessel, then to the tanks forward or aft to level her, and finally to tanks in the center of the vessel. The water admitted to the last tanks does not materially change the inclination of the vessel, and it is admitted in small quantities until the floating power is reduced to from six hundred to a thousand pounds. Gages record the results of each stage. The submarine in this condition exposes about ten feet of her periscopes and is ready for running submerged. The electric motors are then started, and the resistance of the water acting on horizontal rudders and the deck, forces the submarine below the surface. The desired depth is obtained by giving the proper inclination to the rudders and the vessel. In fact, the control of the submarine in changing and maintaining its depth is very similar to the control of a surface vessel when making a passage on the surface. The modern submarine, starting with its main tanks free of water, can totally submerge within three minutes. Such a weapon is not and cannot be a mystery.

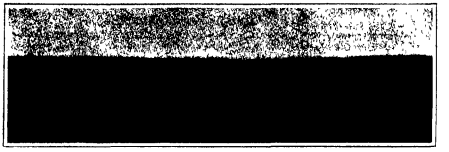
What the Submarine has Accomplished.—The record of the "Davide" before Charleston during the civil war, when a blockading squadron was kept on the move for over a year, three ships injured, and a

urth sunk, proved at that early date the value of the submarine. The radius of action of the "Davids" was limited, that of the modern submarine is almost unlimited. The Division of Submarines now in commission on the Atlantic Coast was actively engaged in cruises, maneuvers, and target practices, from March 1st to November 1st of this year. During that time the Division cruised from Annapolis, Md., to Portsmouth, N. H., and familiarized itself with all harbors along the coast. The harbors of Chesapeake Bay, those of Newport, Provincetown, Boston, Gloucester, Rockport, Portsmouth, and Vineyard Haven Sound were successfully navigated by the submarines in the submerged condition, and, at times, much to the surprise and astonishment of the unsuspecting shipping. The submarines were often separated from the tenders for periods of two to four days and severe weather conditions of gales, snowstorms, and fog were encountered. As the conditions were successfully met from time to time, officers and crews gained confidence in the reliability of the weapon placed in their hands.

While the Division was in the waters of the Chesapeake, three- and four-day cruises away from the tenders were made for the purpose of thoroughly developing the crews. On one of these cruises a gale, accompanied by snow and hail, struck the Division when at anchor in the lower Chesapeake. The blow continued throughout the night and the following day. Two submarines lost their anchors and were forced to keep under way throughout the night, the others rode out the gale without experiencing any serious trouble. All returned the following day to Annapolis against high head winds and seas, that covered the vessels with frozen spray from the tops of the periscopes to the water lines. The ice-covered submarines were such beautiful marine pictures as they came into the harbor that the discomforts of the run up the bay were soon forgotten.

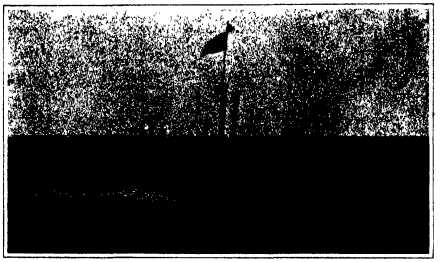
Nantucket Sound and the waters of Massachusetts Bay were repeatedly navigated in fogs. During the operations in Cape Cod Bay, twenty to thirty torpedo vessels, submarines, and surface craft would enter Provincetown harbor at night and in dense fogs. In due course of time after such an exercise, the wireless would flash the signal that all vessels of the submarine Division had returned. The most successful cruise of the Division in a dense fog was a run in close formation from the inner harbor of Gloucester to that of Provincetown without any navigation landmarks having been sighted, and except for a few minutes, the submarines were not visible from one another, although they were less than 100 yards apart. The Division had spent the week-end at Gloucester and the run was made in order that it might report ready for the night attacks on the battleships.

A run, that in many ways simulated war conditions, was made during June from Newport, R. I. to Gloucester, Mass., when practically the entire distance of 190 miles was made by the submarines in the submerged condition. Two stops were made, one at the entrance to Nantucket Sound, the other at Provincetown. The longest time of any one submergence was about twelve hours, and the greatest distance submerged on any one run was about fifty-five miles. During the entire run the submarines were separated from the tenders and were self sustaining in every respect. Less than sixty hours were taken for the run, although no attempt was made to make a record. The battleships, the torpedo craft, and naval militia engaged in combined maneuvers off Newport from July 18th to 20th. The part assigned to the submarine Division approached war conditions almost perfectly. All harbors from Gay Head to Montauk Point that could be used as bases by an invading fleet had to be protected. The disposition of the seven submarines was made accordingly, and they were successful beyond the expectation of the most enthusiastic. In the day problem two succeeded in attacking before the battleships anchored, the others within three hours after they had anchored. In the night attack the invading force pierced the line well to the eastward and only two submarines were successful. The exercise was declared finished before the submarines at the entrance of Long Island Sound had time to come up. The readiness with which the modern submarine can deliver an attack was vividly demonstrated on the morning of the 19th. At 3.40 P. M. on July 18th the "Grayling" anchored on the outer line between Block Island and Gay Head, ready in every respect for quick work. At night lights were screened and a watch of three set. At 4.10 A. M. of the following morning the lookout reported an armored ship to the southward and eastward, distant several miles, and standing to the northward. "All hands" were called at once, hammocks lashed and stowed, thirty fathoms of anchor cable hove in and anchor secured, and preparations made for running submerged. At 4.24 A. M., just fourteen minutes from the time of receiving the first report, the "Grayling" was submerged and running at seven and one-half knots to intercept the armored ship, which proved to be the scout "Washington." At 4.58 A. M. an attack was delivered. The scout was then standing rapidly to the eastward but later returned, and another attack was delivered. After the second attack the "Grayling" rose to the surface in order to impress the scout with the utter folly of carrying on scouting operations so near the enemy's coast. The operations of July and August in Cape Cod Bay were a continuation of the successful work in the sham battle off Block Island.



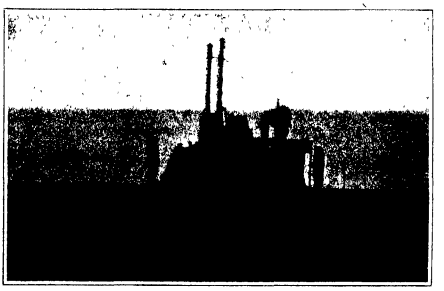
A method of attack developed by the "Narwhal" and "Grayling" off Gloucester is worthy of note as showing the reliance that can be placed in the modern submarine. The "Narwhal," cruising at depths of from seventy to one hundred feet directly under the "Grayling," which was submerged to a depth of fifteen feet, was directed by the "Grayling" for over two hours. The speed of both vessels was seven and one-half knots and the means of communication was the submarine bell apparatus. When the "Narwhal" rose to the surface in obedience to a signal from the "Grayling" she was in her designated position.

The mobility of the Division is shown by the distance cruised during the eight months away from the navy yards viz. 25,000 miles on the surface and 3,800 submerged. The achievements have been accomplished with submarines developed by a commercial company and it is reasonable to suppose that they will be greater when their development is undertaken by the navy.



In view of what the submarine has done can anyone doubt its future?

The Submarine Compared to Other Types of Warships.—The essential military characteristics of a man-of-war are, seagoing and sea-keeping qualities, invulnerability and powerful and destructive armament. A man-of-war to be seagoing and sea-keeping must be seaworthy and habitable in all condition of weather and sea, its motive power must be reliable, it must be readily handled and maneuvered, and it must have a large radius of action. The modern submarine is built to stand the great pressure due to 200 feet submergence,



(Continued on page 656.)

Running submerged, conning tower awash.

The diving rudders are depressed, causing the boat to dive

Knocking down and sending below bridge and deck fittings, preparatory to submerging.

At the surface, showing conning tower, bridge and periscopes.

The Fleet and Its Readiness for Service

[1] Battleships having a main battery of all big guns (11 inches or more in caliber).

[2] Battleships, first class: are those of (about) 10,000 tons or more displacement.

[3] Armored cruisers having guns of largest caliber in main battery and capable of taking their place in line of battle with the battleships. They have an increase of speed at the expense of carrying fewer guns in main battery and a decrease in armor protection, also called battleship cruisers.

[4] Include all unarmored cruising vessels above 1,000 tons displacement.

[5] Includes small battleships and monitors. No more vessels of this class are being proposed or built by the great powers.

[6] Includes vessels of colonies.

Vessels Building or Authorized

[March 1, 1911]

	Battleships, Dreadnought Type	Battleships	Armored Cruisers, Invincible Type	Armored Cruisers	Cruisers	Destroyers	Torpedo Boats	Submarines
England[1]	10		5[2]		18[3]	80[3]		18[3]

Austria	2[6]	1						6

[1] England has no continuing ship building policy but usually lays down each year 5 armored ships, with a proportional number of smaller vessels.

[2] Includes 3 vessels of colonies.

[3] Germany has a continuing shipbuilding program governed by a fleet law authorized by the Reichstag in 1911 there are authorized 3 battleships, 1 armored cruiser, 2 cruisers, 12 destroyers. Eventual strength to consist of 28 battleships 20 armored cruisers, 38 cruisers, 144 destroyers.

[4] $7,550,000 authorized for experiments and further construction.

[5] One more battleship, 2 more armored cruisers, 1 more cruiser and several destroyers and submarines authorized to be laid down and completed by 1916.

[6] Building under agreement with navy department before authorization by legislatures.

NOTE. The following vessels are not included in the tables. Those over 20 years old unless they have been reconstructed and rearmed since 1900; transports, colliers, repair ships converted merchant vessels or any other auxiliaries vessels of less than 1,000 tons except torpedo craft, torpedo craft of less than 50 tons.

A Landsman's Log Aboard the Battleship "North Dakota"—V.

(Continued from page 574)

target. "One hundred down," says the spotter. "What next?" I ask of an officer standing near me. "A six-gun salvo—have you got your ear-protectors in place?" I am raising my hands to press the little bulbs more snugly in position, when there bursts forth a Titanic crash! My whole frame feels as though some unseen hand had struck it a violent blow, and I find myself flung, in the effort to keep my footing, entirely across the platform in the direction of the target (the effect of the recoil) and then flung backward, and then alternately forward and backward, until the fierce whipping of the *mast subsides*.

The spotter looks over his shoulder at me and points at the sky and there I see six, sharply-defined, circular, black spots, symmetrically disposed, in pairs, on a long horizontal line across the heavens—the six shells.

"Baron Munchausen?"

Nay, good reader, question not my veracity, it is a common phenomenon and may be seen at any big-gun target practice when the weather is clear, as it was that day. Steadily, the little ink-black spots diminished and drew together under the influence of the perspective, rising gradually to the highest point of their trajectory, when they faded from sight.

The fire-control platform has quickly steadied to absolute quiet, and we listen with keen attention for the spotter's verdict. Up go those magnificent, flashing bursts of pulverized water, and I hear the spotter call into the mouthpiece: "A straddle," which means that some of the shells have dropped in front and some beyond, making the average of the whole six a hit on the target itself.

Later, a four-gun salvo went clear through the target, tearing part of it away and throwing up the vast tell-tale geysers just beyond.

The physical effect of the blast of these 12-inch guns is something that defies description; but the plate shown on page 583 bears dramatic evidence of the power of the mighty air-wave. The photographer had the temerity to stand on the forward bridge of the "Michigan" to photograph a four-gun salvo from turrets 1 and 2. After the discharge, he found himself on his back on the after side of the bridge, his camera smashed to fragments, but his picture saved, except for the diagonal crack which will be noticed in this illustration, running from left to right—mute evidence of the mishap.

Dramatic in every way is a salvo of the main batteries of a modern battleship. Its appeal to the eye may be judged from the handsome photogravure insert which is inclosed within the present issue.

Later in the day, the net screen which covered the target was brought on board, where it was carefully combed over by the umpires, the ordnance officer, and the spotter, who searched every square foot of it, looking for the coveted ragged rents with as much care as ever a western prospector looked for a color of gold in his pan. The four-gun salvo that carried away a part of the target cost the "North Dakota" dear; for a considerable portion having disappeared, by the rules of the game, and indeed by the necessities of the case, any later shots that may have passed through the gap did not count. For this and other reasons, I could not understand the disappointment of that ship's company when they learned the result—*four hits and six ricochets*. Credit should be given for the fact that since for economy, three-quarter powder charges were used, the sight-bar range was actually about 13,000 yards, or between six and seven miles. To me at least this was a fitting and altogether satisfactory climax to that never-to-be forgotten cruise aboard the "North Dakota."

If the present log has served to give the people of the United States a clearer knowledge of the fine work which is being done in the United States Navy, not only by the "man behind the gun" but also by the man behind "the man behind the gun," it will not have been written in vain.

The landsman's thanks are due to George von L. Meyer, the Secretary of the Navy, to Admiral Hugo Osterhaus, Commander-in-Chief of the Atlantic fleet, and to Capt. Albert Gleaves and the officers of the good ship "North Dakota" for the many courtesies extended during my stay with the Atlantic Fleet on the South ern Drill Grounds.

(*End of Landsman's Log. For earlier chapters see issues of October 14th and 28th and November 11th and 25th.*)

Our Rank Among the Naval Powers

(Continued from page 581)

increase the number of merchant vessels flying the American flag, the navy will have to depend upon its own colliers in time of war, or purchase or charter merchant vessels in foreign countries—probably the former, as the risks under charter would be considered too great. Such a procedure would be most uneconomical, as greatly increased prices would no doubt be demanded, our needs being known.

In the event of actual hostilities, the supply of ammunition to a fleet is the most important factor. The battleships of the present day carry ordinarily about 100 rounds for each of the heavy guns. In the event of hostilities by stowing magazines and shell-rooms to their fullest capacity, this amount would probably be increased to about 120 rounds per gun.

When we take into account the rapidity of fire of the heavy guns of a modern battleship, and the range at which an action will begin, it would not seem improbable if the total amount of ammunition would be shot away in an engagement with an enemy without either fleet gaining such a marked advantage as to make the action decisive and final.

If such action takes place in close proximity to the shores of the enemy, it would not be very difficult for its fleet to withdraw temporarily to a fortified basis and replenish rapidly its magazines and shell-rooms. The question presents more formidable difficulties for a fleet operating at a great distance from a base. Ammunition must be carried to the fleet in properly equipped ammunition ships, ships so fitted as to be able to rapidly discharge their ammunition into the battleships. Arrangements can be made by which a limited amount of ammunition can be carried by all auxiliaries, including colliers, supply ships, repair ships, transports, etc., but these ships must be especially fitted for carrying the ammunition, and at the best can carry but a limited quantity.

Other necessary adjuncts of a well balanced fleet are repair ships, hospital ships, transports and mine laying vessels.

Repair Ships.

It is believed that if any fleet is accompanied by a sufficient number of properly equipped repair ships, it will be necessary for said ships to visit our dock yards only at very distant intervals, primarily for cleaning their bottoms. Numerous small accidents to the machinery or appurtenances of a modern battleship can be readily and efficiently repaired by a properly equipped repair ship. After an action between two fleets, the value of a repair ship cannot be over-estimated. Many ships of the fleet may be damaged in such a way that they can be temporarily repaired and fitted to take their place again in the line of battle by a repair ship.

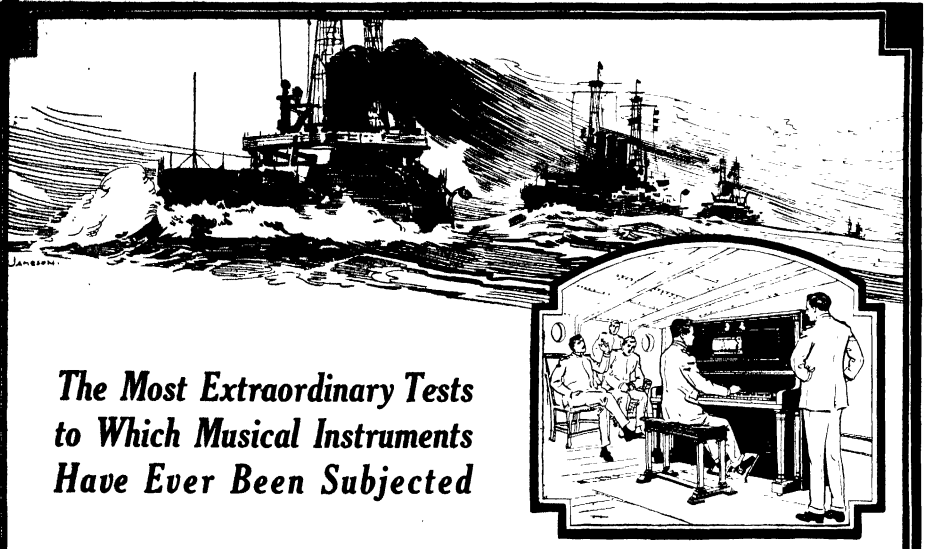
The United States possesses but one ship of this type as opposed to three in England and two in Germany, and while the Merchant Marine of this country may possibly furnish a number of ships suitable for this purpose, time will be required to install in such ships a proper equipment.

Hospital ships, while a necessary adjunct to the fleet, can undoubtedly be acquired by purchase or contract of vessels under the American flag or in foreign countries, as said vessels act under the Red Cross Agreement and are not to be considered as subject to capture so long as they perform the duties for which they are designed. Transports for the conveying of bodies of troops and advanced base outfits can probably be acquired by purchase or contract preceding hostilities, and will probably only be needed in the event of distant operations of the fleet, where it becomes necessary to seize and defend a base, to which vessels of the operating fleet can repair at intervals for coal, fuel, ammunition, or other supplies.

Submarines.

In the present state of naval development, the submarine is essentially a vessel designed as an important part of the mobile defenses of our coasts or outlying possessions. It is understood that the French Government is now designing and building a type of submarine, which it is believed will be able to accompany the fleet even in distant operations, its radius of action and habitability having been developed to the extent which makes such a use of this type of vessel a probable success. Of this type, the submarine, England possesses seventy-four, Germany fourteen, United States twenty-six, France sixty-six, Japan ten, and Russia thirty-one.

Personnel.



When we come to consider the number of commissioned officers and enlisted men available for duty in the fleet, we find that the United States Navy is sadly deficient. Although the number and size of our vessels of war have increased very largely in the last ten years, there has been no proportionate increase in the commissioned personnel of the Navy. If the Navy Department were called upon to-day to commission all of its fighting vessels now in reserve, and which, in the event of war, it would be necessary to place in service, it would be impossible efficiently to officer and man these vessels. Of late, when it has been found necessary to commission some new battleship cruiser, or even torpedo destroyer, it has been found equally necessary to place some vessel of the same type in reserve or out of commission, in order to provide the personnel for the new ship.

It is difficult to compare conditions between countries which have compulsory military service and countries where service in the navy is purely voluntary. England, although compulsory military service does not exist, maintains a very strong reserve of both officers and men. In all other European navies compulsory service exists, so that these countries are from year to year building up a reserve of officers and also of trained men, who have served at least three years with the colors.

In Germany this is a most important factor, as with their system, which carries a man along either in active service or in the reserve until he reaches the age of 45 years, a very large body of trained men is available, in the event of hostilities, for commissioning all ships in reserve, or for other purposes. So far as the commissioned personnel of the United States Navy is concerned, it compares most favorably in education, training and experience with that of any other country, but in numbers it is wholly inadequate for the present and future needs of the Navy.

The analysis of the composition of the various fleets, by which their strength and relative rank is measured, shows that Great Britain holds, beyond a shadow of a doubt, the first place. Considering the navies of the United States, Germany, France and Japan, it is clearly seen that the United States outranks France and Japan, as the superiority of our battleship fleet is so great as to offset every advantage they may possess in the other elements which make up naval strength.

To establish the relative positions of Germany and the United States is more difficult. Our only superiority lies in the battleships themselves; in all other essentials of fleet strength, we are outranked. Giving due weight, however, to all factors, it would seem that at the present writing the margin of superiority rests with our fleet, a margin so slight that, considering vessels building and authorized, two or three years will undoubtedly relegate the United States to third place among the nations.

The Most Extraordinary Tests to Which Musical Instruments Have Ever Been Subjected

Twenty-six Pianola Pianos on the 45,000 Mile Cruise of the American Battle Fleet

When Admiral Evans' fleet began its memorable cruise around the world from Hampton Roads, there were twenty-six Pianola Pianos distributed among the different ships.

The Battle Fleet covered over 45,000 miles in its trip, crossing the equator four times. It passed from the extreme cold of the Straits of Magellan to the heat and humidity of the tropics.

During target practice in Magdalena Bay and at Manila every object on board was subjected to terrific strain. In one instance, the force of concussion as the big guns were fired, was sufficient to bend in the steel bulkheads of one of the mess-rooms, where a Stuyvesant Pianola Piano was installed.

In two cases, during the storm encountered between Manila and Yokohama, Pianola Pianos broke loose from their fastenings and were hurled to the other side of their mess-rooms, before they could be secured.

Yet the Pianola Pianos in these rooms when examined four months later needed only slight adjusting and were very little out of tune.

These Pianola Pianos were the common property of the different messes to which they belonged. They were not played by one or two people as would be the case in a private home, but were used by anywhere from a dozen to a hundred or more different individuals.

According to the testimony of the officers and men, the different Pianola Pianos were played almost continuously during the whole fourteen months of the cruise, and shared with the big guns the interest of all visitors who came aboard.

On the return of the fleet, a special representative of the Aeolian Company was sent to Old Point Comfort to inspect these instruments. *Without exception every Pianola Piano examined was found in excellent playing order.*

Besides tuning and such slight regulation as fourteen months constant use would naturally involve, they were practically in *as good condition as when the fleet departed.*

* * * * * *

It is of the utmost importance that the distinction between the Pianola Piano and other so-called Player-pianos be understood. Only pianos containing the genuine Pianola and bearing the word "Pianola" upon the fall-board are Pianola Pianos. In the means it provides for artistic playing—in its musical quality as a piano and in its durability as assured by the thoroughness and fidelity of its construction—the Pianola Piano occupies a class apart from, and superior to all other instruments of its type.

Recent Development in Ordnance

(Concluded from page 581)

Armor.

There has been no important advance in quality of armor since the Krupp process of hardening was introduced about fourteen years ago, during this period the side armor belts of our battleships have been of from nine to eleven inches thickness To meet the increasing power of guns and penetrative effect of projectiles, a tendency toward increasing this thickness to twelve or thirteen inches is evident, and the Bureau of Ordnance has even had one experimental eighteen-inch plate made and tested with a view to possible future demand for armor of that thickness

That the art of armor making has not stood still, in spite of there having been no radical changes in methods is shown by the two photographs on page 520 The former shows an armor plate produced in 1905, and the latter a plate produced in 1911, against each of which three projectiles have been fired In the one case the flaking of the hard surface was excessive, in the other almost nil It will be noted that neither plate was completely penetrated

This plates, which are not technically classed as armor, have been much improved in resisting power by changing the alloy used, a nickel-chrome-vanadium alloy has been adopted, and this when specially treated produces turret and conning tower tops of great resistance

Experimental Work.

Much valuable information has been obtained by experimental firing at the U S S "Katahdin" and "San Marcos" (formerly "Texas") Each of these is a vessel of small military value, but capable of affording an actual target for experimental firing The "Katahdin" was fitted with armor plate targets erected on her upper deck, one target represented the side of a battleship, the other a turret barbette, and in both the armor plate was braced by appropriate framing and structures Firing was conducted with a 12 inch gun on board the U S S "Tallahassee" at ranges of 7,700 to 8,500 yards, using service ammunition, but not with explosive shell, as the object was solely to determine penetrative effect Two hits were scored on each target with resultant complete penetration of the armor, as was expected in accordance with theoretical calculations The results of this test also proved that a projectile while in flight is at all times tangent to the trajectory

The 'San Marcos' furnished a target for more extensive firing the greater part of which was conducted by the U S S "New Hampshire" for purposes of gunnery training of the personnel The most striking lessons of this firing were

(1) The fact that, at ranges of 10,000 and 12,000 yards, the "New Hampshire" could place her shots on any portion of the ship at will, thus proving the accuracy of her spotting and pointing

(2) The tremendous havoc wrought in the "San Marcos" by the passage or bursting of entering shell

Modern Submarines

(Concluded from page 581)

therefore it is apparent that none of the surface elements can damage it Its natural subdivision into tanks for submerging purposes gives it a safety which every surface craft strives for by putting in double bottoms There is no smoke, no leaky or hot steam pipes, or any other of the numerous disadvantages of the ordinary surface vessel The reliability of the motive power, the internal combustion engine, is assured, and the modern submarine being a twin-screw vessel is readily maneuvered The radius of action of submarines now under construction exceeds 5,000 miles on the surface and 100 submerged, the maximum speed on the surface being 13½ knots, that submerged 10½ knots Ten miles is the farthest that a submarine can be seen on the surface, and its submerged radius of action is such as to permit many hours of maneuvering unseen and unsuspected, beneath the surface The comfort of the crew depends entirely on the weather and sea as it does in all craft. The submarine may escape from heavy weather

Admiral Mahan's New Work
NAVAL STRATEGY
Compared and Contrasted with the Principles and Practice of Military Operations on Land
By ADMIRAL A. T. MAHAN
This new work, just issued, contains the results of almost a lifetime's study of the subject, by the world's foremost authority on naval matters.
With 13 Maps and Plans. 8vo. Cloth, $5.00 net.

The Edison Storage Battery

"Built like a watch but as rugged as a battleship"

AS GREAT AN ADVANCE IN WORLD PROGRESS AS WAS THE

Edison Incandescent Lamp

Tremendously superior to all other storage batteries because:

It embodies an entirely new and correct principle.

It is lighter and vastly more durable.

Excessive vibration and concussion do not affect it.

No damage done by prolonged and oft repeated overcharging.

No injury from remaining idle in a charged or totally discharged condition indefinitely.

Extremely small loss of charge while standing idle.

Contains no acid, therefore no acid laden gases evolved.

No injury to metal work from gases.

No personal discomfort from gases.

It prevents asphyxiation of a submarine crew in event of prolonged enforced submersion, because of the affinity of its solution - potash - for carbonic acid gas.

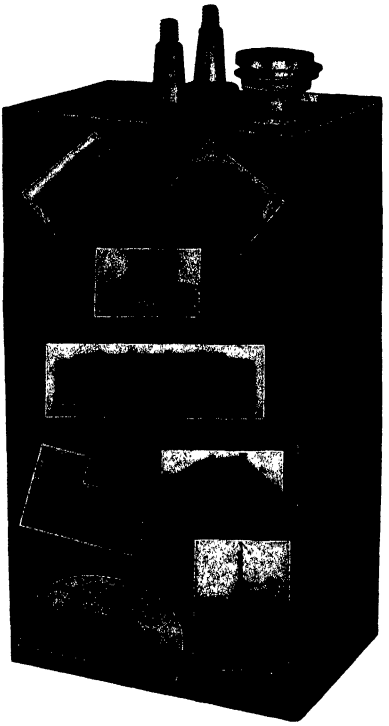
Short-circuiting does it no injury.

It maintains its capacity for many years.

No buckling or growing of plates.

No plate renewals.

No shedding of active material.



No sediment in jars.

No cleaning of jars.

No breaking of jars.

No sulphation or corrosion of parts.

No expert attention required.

It has changed the entire aspect of the electric pleasure vehicle situation.

It makes the electric truck a profitable investment by eliminating battery repair and renewals and ensuring reliability.

It banishes unsightly trolley wires for street car propulsion.

It makes the electric locomotive a safe proposition in mines and powder mills.

It renders expensive railway terminal electrification unnecessary.

It changes taxicab operation from loss to profit.

It solves the train lighting problem.

It has added new use to country house lighting.

It practically doubles the strategic efficiency of the submarine and will outlast any boat in which it is installed.

It can be relied upon for power in emergency, for illuminating magazines and handling rooms, hoisting ammunition, operating turrets and laying guns.

It is dependable for sight lighting and gun firing, even if charged only once in six months, and is the only storage battery made that will stand up to concussion of gun fire.

IT WILL OPERATE YOUR KLAXON HORN ONE YEAR ON ONE CHARGE; WILL LIGHT YOUR CAR, RUN YOUR IGNITION SYSTEM, FURNISH POWER FOR YOUR ELECTRIC SELF STARTER AND LAST FOR MANY YEARS.

Manufactured in Sizes from 1 Ampere-Hour Portable to the 15,000 Ampere-Hour Submarine Types

We are running an interesting continued story on the Edison Storage Battery Development, Theory, Construction, and Application, in the advertising columns of the Army and Navy Journal, Beginning with the weekly issue of October 21, 1911, and addressed to the personnel of the Army and Navy. They are of general interest, judging from the widespread favorable comments we are receiving.

34 YEARS' EXPERIENCE IN THE MANUFACTURE OF HIGHEST GRADE MECHANICAL VEHICLES

ALCO
Motor Trucks

65 Per Cent of all Alco Trucks are Owned by Million-Dollar Companies

And 62 per cent of all Alco Trucks are Re-orders

BIG concerns own Alco Trucks—big concerns like the American Express Company, Gulf Refining Company, Barrett Manufacturing Company, Gimbel Brothers, Standard Oil Company, Singer Sewing Machine Company.

Big companies, like big men, don't make many big mistakes.

They are shrewd. They know.

Sixty-five per cent of all Alco Trucks are in the service of companies rated in Bradstreet's at $1,000,000 or more.

This is only natural, for the American Locomotive Company is itself a big company. Capital $50,000,000. And of considerable transportation experience—dating back to 1865. Builders of 50,000 locomotives.

Knowing this, these big companies felt that the American Locomotive Company *ought* to build a good truck. It had experience no one else possessed, extensive capital, large physical equipment, an organization already at work. Whether or not it really *had* built a good truck must be determined by actual service.

This was the logical reasoning upon which nearly every single big company made its *first* Alco purchase.

And since its first purchase every single big company has ordered *more* Alco Trucks! Every single one!

And sixty-two per cent of all Alco Trucks were purchased on such repeat orders!

In the service of Department Stores 78 per cent are re-orders; Oil Refiners, 74 per cent; Express Companies, 64 per cent; Packers, 53 per cent; Brewers, 50 per cent—the five lines of business in which motor trucks are most used today.

Repeat orders speak with eloquent emphasis of satisfied owners—stronger than mere claims—*powerful* testimonials.

These are compelling facts. They tell the smaller business man that he can avoid an unwise purchase if he selects the Alco.

They are evidence which must determine the verdict.

Our new book is full of vital facts. Write for it today.

AMERICAN LOCOMOTIVE COMPANY

1886 Broadway *Builders of Alco 6-cylinder and 4-cylinder Motor Cars and Alco Taxicabs* New York

Movers of the World's Goods since 1836

Capital, $50,000,000

by remaining under the surface. This was actually done by the "Snapper" in 1916, when she remained on the bottom off Boston Light Vessel in seventy feet of water for 12½ hours.

The invulnerability of the submarine is well nigh perfect. In its approach, after sighting the enemy, its invisibility affords better protection than any armor or watertight subdivision that has been put abroad in surface vessel. The exposure of as much as five feet of one or more periscopes, each six inches in diameter, is necessary, in an attack, for periods of two to five minutes, although with that amount of the periscopes exposed there is still fourteen feet of water over the hull, which is ample for protection.

The armament consists of the torpedo tube and the torpedo. History teaches that the gun has always decided the naval battle, and admitting that to be true, may there not be a change in the character of the gun? It is a very simple matter to designate a torpedo tube as a gun and a torpedo as a projectile. In fact the similarity is so marked that it is surprising that they were not so named at the beginning.

Let the world become imbued with the belief that in the modern submarine there is nothing wonderful, weird, or unusual, and that duty aboard is not a hazardous undertaking, and a new era in the development of naval warfare will have commenced.

A Geographical Excursion Across the United States

IT is announced that the American Geographical Society, which celebrates its jubilee next year, is planning in connection therewith a transcontinental excursion for the purpose of geographical study, in which delegates from the geographical societies of other countries will be invited to participate. The party will be "personally conducted" by Prof W M. Davis, of Harvard, who has lately had experience in carrying out similar undertakings in Europe. It is expected, also, that the American members of the party will, so far as they are able, act as guides for the foreign visitors. While the natural features of the landscape are to be the principal objects of observation, attention will also be paid to the agricultural and industrial development of the country.

It is expected that the excursion will leave New York some time in August, 1912, on a special train, and will spend six or seven weeks in traversing the country. The itinerary, as now planned, is to include, among other points of interest, the highlands and gorge of the Hudson, Niagara, the shore-lines of old lakes in Ohio, the southern end of Lake Michigan, with its artificial outlet into the Mississippi system, the upper Mississippi and Missouri, the Yellowstone Canon and National Park, the Rockies of southern Montana, the Cascade Range, Seattle, and Puget Sound. The return will probably be made by a southerly route.

Fishing With a Steam Pump

ONE of the most singular fishing devices imaginable was discovered by accident in France. Though extremely simple, the system is revolutionary.

A pond on the farm of La Marlequette, bordered by rocky shores, was drained one year by the aid of a steam pump. Each stroke of the piston drew up twenty-five gallons of water and the pond was emptied in a few hours, and not only was the water drawn off, but all the fishes also were transferred to a new element.

This was a revolution. The owners of ponds in the neighborhood followed suit, and the proprietor of the pump made a specialty of this sort of work. He "let" one of his pumps, modified for the purpose. The peasants of the region called it "the fish pump." Each stroke of the piston brought up torrents of water, in which were fish and crawfish, together with mud and débris.

One pond of several acres was cleared of fish at an expense of 36 francs, or $7.20. The process was ingenious, but as one cannot have his fish and eat it, too, and as such rapid consumption would have led to equally rapid extermination, the local authorities were obliged to take measures to stop the practice.

The "Cravenette" (Reg. U. S. Pat. Off.) PROOF

"Cravenette" *is a proof, not a cloth*

It is the only proof that will make any cloth *permanently rainproof without the use of rubber.* It permeates every fibre of the yarns of which a cloth is woven, rendering them **thoroughly rain proof.**

This proof prevents a cloth from becoming water-logged, soggy, heavy or wet from rain, snow, fog or dampness of any kind. It is permanent, contains no rubber and does not change the appearance of the cloth in the least.

This circular registered trade mark is stamped on the back of every yard of "Cravenette" proofed cloths

For further information write us.

Cravenette Co., U.S.A.

Factory, Hoboken, N. J. N.Y. Office, 100 Fifth Ave.

Jaeger SANITARY

The many who have worn **Jaeger Underwear** do not need to be told of its merits. The few who have not should lose no time in adopting it, as it benefits pocket as well as health in the end.

All weights for all wants

Dr Jaeger's S. W. S. Co.'s Own Stores
New York: 306 Fifth Avenue, 22 Maiden Lane.
Brooklyn: 504 Fulton St. Boston: 228 Boylston St. Philadelphia: 1516 Chestnut St. Chicago: 126 N. State St. *Agents in all Principal Cities.*

CONGRATULATIONS PIPE SMOKERS

Here's a pipe you can keep clean and dry without taking any time or doing any dirty work. It means good health to you and improved flavor to any tobacco. A wonderful gift for every smoker. No knocking or scraping to keep this pipe right. One twist of the patent bowl and it's ready for another smoke. The cleaner is part of the pipe—can't be mislaid, takes no space.

"DEFI" SELF CLEANING PIPE

The briar bowls used in all "Defi" pipes are seasoned by a scientific secret process.

"Defi" superSorbty.

Four styles, straight or curved stems. French briar bowls. Rimm solid rubber bit. Send 75 cts. Style E. Style G. $1.00. Style N selected French briar, sterling silver mounted. $1.50. The name "Defi" is on bit and bowl.

For Christmas. Style M, genuine cather bit, beautiful silver mounting in a handsome leather case, with hologist pouch. $2. *Correspondence from clubs solicited.*

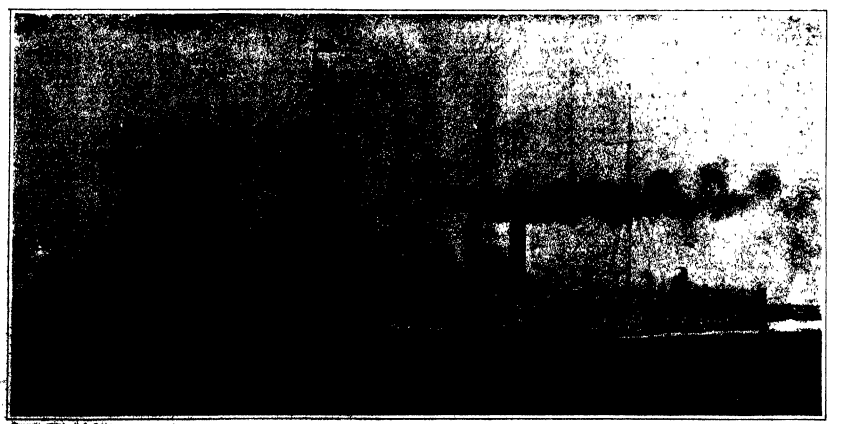
DEFI PIPES, Dept. 84, 131 W. Austin, N.Y.

EVERSTICK INVISIBLE SHOE

Insures foot comfort, health, prevention and good appearance. They keep feet dry, warm in cold weather and dry in cold weather, and can be worn all day long without discomfort or discomfort. EVERYBODY NEEDS EVERSTICKS. Always for sale where good shoes are sold. ACCEPT NO SUBSTITUTES. THE ARCH & FORD CO. Cleveland, Ohio

U. S. Torpedo Boat Destroyer "Reid"—*Fastest vessel under American Flag.*

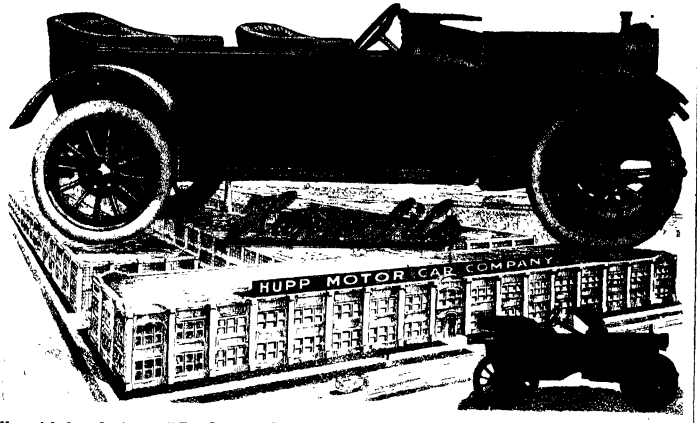
Making 34.58 knots Built by Bath Iron Works Limited



Bath Iron Works, Ltd.

BATH · MAINE · U · S · A

Builders of Torpedo Boat Destroyers, Torpedo Boats, Fast Steamers and Yachts



Parsons Marine Steam Turbines and Normand Water Tube Boilers
Specialists in Light Construction and High Speed

Estimates cheerfully furnished to meet the most difficult requirements

Length, 420 feet. Beam, 47 feet. Displacement, 4,750 tons. Speed, 26 knots. Maximum coal supply, 1,450 tons. Armor: Deck 1½-inch
Guns: Two 5-inch; six 3-inch. Torpedo tubes, two 21-inch.

U. S. Scout Ship "Chester"

Hupmobile Long-Stroke "32" Five Passenger Touring Car—$900

F O B Detroit, including equipment of windshield, gas lamps and generator, oil lamps, tools and horn Three speeds forward and reverse, sliding gears Four cylinder motor, 3¼ inch bore x 5½-inch stroke Bosch magneto 106-inch wheelbase 30 x 3½ inch tires Color—standard Hupmobile blue

The new touring car will be first exhibited at the Grand Central Palace, New York, Jan 10 17, and subsequently at the principal automobile shows throughout the country

Hupmobile Runabout—$780 f o b Detroit, including top wind shield gas lamps and generator, three oil lamps, tools and horn Four cylinders 20 H P sliding gears Bosch magneto

In the new Hupmobile plant, now nearing completion, which will have when finished a capacity of 15 000 to 20,000 cars a year the Runabout—sleeves a car of unprecedented popularity will continue to occupy the same large part in our manufacturing plans that it does at present.

Hupmobile Coupe—Chassis same as Runabout—$1100 f o b Detroit

Hupmobile Roadster—Chassis same as World Touring Car—$850 f o b Detroit

A totally new idea of what you ought to get for $900

A new and larger Hupmobile which immediately thrusts upon your attention a score of *tangible superiorities* which set it in a class apart from cars of its price.

A five-passenger Touring Car for $900 which *rejects every characteristic of commonplace construction;* and makes clear its invasion of the field above that price; by points of difference and departure which no motorist can mistake.

Evolved out of the experience which has built thousands of the Hupmobile Runabout the quality car today, as it always has been, of the runabout class.

Designed by E. A. Nelson, Chief Engineer of the Hupp Motor Car Company since its inception and designer of the original Hupmobile Runabout. To him and the skilled shop organization which he has continuously maintained, we owe the inimitable lines, the marked simplicity, the efficiency and the high quality of workmanship incorporated in the Runabout.

Impressed with the same strong individuality as the Runabout; and still further removed from comparison by:

First, the small-bore, long-stroke motor. Second, the body design and construction which attains the purpose of the "underslung" and avoids all of its disadvantages; and Third, the Americanization, after close study abroad, of invaluable *engineering principles* entirely new to this country.

These highly specialized features speak so plainly of greater structural soundness, more progressive engineering principles; and costlier and more careful shop practice, that it is obvious, they proclaim a product without precedent at the price

Small-bore, long-stroke motor—3¼x5½ inches—60% more pulling power for mountain work and heavy roads, 4 to 50 miles of speed, ability to pick up quickly without feeling the weight of the car, or throttle instantly to a walking gait

Unit power plant

Cylinders cast en bloc, with three bearing crankshaft (found only in other cars selling upward of $2500) instead of two Bearings extra large, having bronze back, Babbit lined.

Valves enclosed by pressed steel cover, keeping oil in and dirt out—noiseless, minimum wear, minimum adjustment.

Thirteen-inch multiple disc clutch, action positive, smooth and easy.

Transmission gears of 40 H P size, run slowly and quietly.

Full floating rear axle, amply strong for a seven passenger car.

Aluminum crank and gear case; drawn steel used in parts where lightness and strength are requisite.

4½ x 8½ Photogravure Free

Write for detailed description and the 4½x8½ photogravure of the new touring car

Hupp Motor Car Co., 1233 Jefferson Ave., Detroit, Mich.

Classified Advertisements

Advertising in this column is 7½ cents a line. No less than four nor more than 13 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

AUTOMOBILES.

A NEW WHITE STEAMER. Model O-O, complete with top. Will sell at a very reasonable price. Address A. A. Hopkins, 963 St. Nicholas Ave., New York City.

AUTOMOBILES AND MOTORCYCLES.

AUTOMOBILES, $50.00 up; Motorcycles, $30.00 up; guaranteed for one year, shipped freight prepaid. Largest list and lowest prices in the world. Ellis, Automobile Broker, Dept. S. A., 215 West 125th Street, New York City.

BUSINESS OPPORTUNITIES.

A STRONG old established, manufacturing company, with a national selling organization, wants to add a new line of building material or composition specialty to manufacture and sell. Address X. Box 775, New York

FREE SAMPLE goes with the first letter. Something new. Every firm wants it. Orders from $1.00 to $1000. Nice pleasant business. Big demand everywhere. Write for free sample. Metallic Co., Co. 438 N. Clark, Chicago.

GOLD DREDGING MINES very rich in Colombia. Mining Engineer wishes partner, will give liberal inducements, big profits, best of references. Address (e mail only), S. Pickelmann, 30 West 8th street, New York.

INVENTORS.—Send a copy of your patent to us and we will send you our pamphlet outlining our liberal manufacturing offer. For further particulars address, Atlantic Supply Co., Long Branch, N. J.

HELP WANTED.

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly. No former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a profitable business. No soliciting or traveling. This is an exceptional opportunity for a man in your locality to secure a lifelong business without capital and become independent for life. Write us today for full particulars. Address E. R. Marden, Pres., The National Co-Operative Real Estate Company, L 84 Marden Building, Washington, D. C.

PATENTS FOR SALE.

BASIC PATENT No. 961,057 of a "Inner-Illuminated," two-light interchangeable-ad., Revolving Sign, for sale, outright, royalty or stock rights. It is the most attractive and inexpensive sign invented. No competition, fully developed, and the market demands it. "Inventor," 1008 Broadway New York.

PROPOSALS.

PROPOSALS FOR BRICK DORMITORY, CENTRAL STEAM HEATING AND POWER PLANT Department of the Interior, Office of Indian Affairs, Washington, D. C. November 16, 1911. Sealed proposals, plainly marked on the outside of the sealed envelope: "Proposals for Brick Dormitory, Central Steam Heating and Power Plant, for the Rapid City Indian School, South Dakota," and addressed to the Commissioner of Indian Affairs, Washington, D. C., will be received at the Indian Office until 4 o'clock, p. m., December 26, 1911, for furnishing materials and labor for the erection of a brick dormitory, central steam heating and power plant, at the Rapid City Indian school, South Dakota, in strict accordance with the plans, specifications and instructions to bidders, which may be examined at this Office, the offices of the Supervisor of Construction, Denver, Colorado, the American Contractor, Chicago, Ill. Roth the American New York City, the Improvement Bulletin, Minneapolis Minn., the Journal, Rapid City, South Dakota, the Bee Hive, Mpls., Minn., the United States Indian Warehouses at Chicago, Ill., St. Louis, Mo., and Omaha, Nebr. the Builders And Traders Exchange at St. Paul, Minn. and at the school. For further information apply to the superintendent of the Rapid City Indian School, Rapid City, South Dakota. C F Hauke, Acting Commissioner

REAL ESTATE.

TEXAS INVESTMENTS.—Buy farm orchard garden lands near Houston the greatest and most prosperous city in the southwest, where values are going up all the time and fortunes made in real estate in short while. Easy terms if desired. Single crop pays for land; several crops annually. Address R. C. Robertson, 301 Kiam Bldg., Houston, Tex.

WANTED.

WANTED—Purchaser for Lilley's patent Bracket. Patented in five countries. A very low price will be accepted. For further particulars address, Bracket, Box 775, New York.

WANTED—One chemist at $6.00 per diem, two first-class laboratorians at $5.00 per diem; one second-class laboratorian at $4.00 per diem and two fourth-class laboratorians at $3.00 per diem. Such a competitive examination will be held January 8, 1912, at the Navy Yard, Washington, D. C., for filling the above positions at the Naval Proving Ground, Indian Head Md. For further information address, "Commandant, Navy Yard, Washington, D. C."

MISCELLANEOUS.

RUPTURE. A new patented device worn in place of the ordinary truss. Simple, comfortable, and most positive. Endorsed by leading surgeons. For particulars address J. D. Rowe, M. D., Tiffin, Ohio.

FREE TUITION BY MAIL. Civil Service, Drawing, Engineering, Electric Wiring, Agricultural, Poultry, Normal, Academic, Bookkeeping, Shorthand Courses. Matriculation $5. Tuition free to first applicants. Apply to CARNEGIE COLLEGE, ROGERS, OHIO.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture such goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service, except that it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated. MUNN & CO., Inc.

Inquiry No. 9040.—Wanted, addresses of owners of locomotives now running not less than 60 inches gage.

Inquiry No. 9041.—Wanted, addresses of owners of locomotive cranes suitable for heavy castings.

Inquiry No. 9042.—Wanted, addresses of makers of bar yarns.

Inquiry No. 9043.—Wanted, address of maker of Spratt's dog biscuits.

Inquiry No. 9044.—Wanted, addresses of manufacturers of radiators, tanques, and driers suitable for making tannic acid.

Inquiry No. 9045.—Wanted, the name and address of manufacturer of lead pencils suitable for use as a stencil for marking on oil.

Inquiry No. 9046.—Wanted, to buy a patent solicitor, a hydraulic ram which would be purchased on a royalty basis. It must be about four inches [illegible]

Inquiry No. 9047.—Wanted, the addresses of persons having [illegible] for the manufacture of [illegible]

Inquiry No. 9048.—Wanted, the address of a firm that manufactures [illegible]

The Diesel Engine and the American Merchant Marine

To the Editor of SCIENTIFIC AMERICAN

In a recent issue comment was made in your columns on the failure of the American inventor to keep pace with his European rival

In the issue of October 7th, a very interesting article appears on the Diesel engine and its economy over the steam engine, especially when applied to ocean-going steamers

One of the remarkable, as well as regrettable conditions, as far as our shipbuilders are concerned, is the indifference displayed to improvements in hull and motive power, particularly motive power, that have appeared in foreign-built tonnage in the past few years

Foreign steamship builders are experimenting with the producer-gas engine, seeking to ascertain its economy as compared with the usual type of three-cylinder engine used generally in steamships, the oil-burning motor marine engine has been given a long test by foreign marine builders, and several steamers to be operated with gas engines are to engage in the trans-Atlantic trade this coming year, and possibly this fall will see one or more gas-driven ocean liners headed for our shores. These steamers that promise to run across this year will be passenger as well as freight

Europe has no oil or fuel, it has to be imported, while the United States is the greatest producer of oil in the world, and yet our shipbuilders lag far and away behind the foreign steamship builder in applying the oil and gas engine to marine service

It is fair to speculate on what causes the paralysis of the American shipbuilder, and one of the apparent causes is that it is shielded too much from competition

The coasting trade—and by the coasting trade is meant every port in the United States and Alaska—from Eastport, Me., on the extreme northeast to farthest Alaska, in the northwest including Porto Rico, is called American coasting trade, and only American built vessels can engage in the trade now, this gives a monopoly to the shipyards of the United States, and shielded from foreign competition the necessity for developing new and improved types of engines and steamers is not found necessary

As to seeking to compete with the foreign builder in the steamship trade of the world, the American gave that up long ago; the only way that he can see, to get even the smallest footing in that trade, is for the government of the United States to pay him for making the attempt

This attitude is the more surprising, as we make iron and steel far cheaper than can any other country in the world, while our exports of iron and steel the past year have been of tremendous volume and the competition of foreign nations in these articles is of no avail against the American manufacturer It is also true that the report to the Stanley committee made by the United States Steel Corporation showed that it sold steel plates $8 to $11 per ton under the domestic prices

That, evidently, is one reason why our shipbuilders cannot compete with the foreign builders; that condition can be remedied by putting steel and iron on the free list, and with these commodities free, Independent yards would be started that would not be so conservative in applying the most modern development in marine engineering to ocean tonnage

The Panama canal will be opened in a couple of years; already one American line is to bid on the contract offered by the Postmaster-General for a line between the American and Pacific ports of the United States, and already it is given out that the steamers this line will require to carry out the contract if secured will tax the capacity of our coast yards, when combined with the government work. Further government contracts must be considered only on a different basis.

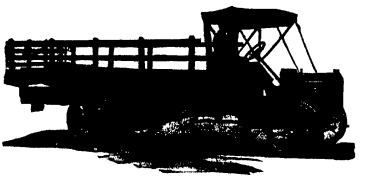
[illegible] that, in a few years, will show all a tremendous rate. Alaska has mineral stores that will keep a mighty fleet busy, to say nothing of the trade between Honolulu, Philippines and the United States It is true that the Philippine carrying trade is not yet confined to American built steamers, and it is lucky it isn't, for there is no American tonnage to-day that would engage in it except at prohibitive freight rates

If ever there was a time propitious for the restoration of the American flag to the deep sea trade, it is now. The new development in marine engineering will make the vast foreign tonnage built up to the present time practically obsolete. As stated in your issue of October 7th the economy of the Diesel engine is so great, that no coal-burning steamer can compete with the motor-driven And yet we have still to learn of any interest being taken in this new marine departure by any American shipbuilder It was the same with the turbine engines We followed far behind Europe, even in the experimental state

We were far behind Europe in taking up the automobile and the airship It is true that we came to the front with a rush, and we may do so in shipbuilding eventually What our iron and steel industries need is, less coddling by the government, the stimulus of competition will enable us to achieve a place in the deep-sea carrying trade of the world that subsidies will never secure for us

And again it becomes apparent that the tonic of free ships would be of immense benefit to our deep-sea foreign trade A free ship bill now would allow our people to invest in these modern motor-driven ocean steamers and establish the American flag in the carrying trade of the world, and the old bugaboo of the American wage scale would be of little consequence in this type of steamers as the coal heavers would be a thing of the past

Chicago, Ill CHARLES DEPEREE



Nitrogen and the Soil

To the Editor of SCIENTIFIC AMERICAN:

I am in receipt of a copy of the letter of Drs Lyon and Bizzell of Cornell University

Their contention that they were the first to announce the fact that non-legumes may secure a part of their combined nitrogen from legumes (when the two are growing together) should be qualified According to their own admission, their first article was received by the editor of the *Journal of Industrial and Engineering Chemistry* on April 21st, 1910, and appeared in July, 1910 The inclosed letter from Prof A D Hall, Director of the Rothamsted Experiment Station, and editor of the *Journal of Agricultural Science*, will show you that my article was received by him in August or early September of 1909 Unfortunately, however, the issue of the number of the *Journal of Agricultural Science* containing my article, was delayed for more than a year, and the article in question appeared in print, therefore, in 1910, instead of 1909 In this article of mine, I state distinctly that the non-legumes, separated by a porous wall from the legumes, were able to obtain very considerable quantities of combined nitrogen Furthermore, the photographs show distinctly the benefit derived from the association I did not submit analyses, even though those had been made, since I did not regard it necessary to submit figures in a preliminary publication Furthermore, the bulletin published by Drs Lyon and Bizzell, and entitled "A Heretofore Unnoted Benefit from the Growth of Legumes" is dated March, 1911. In other words, this was submitted to the printer several months after my article in the *Journal of Agricultural Science* appeared in print According to the admission of Drs. Lyon and Bizzell, the number of the *Journal* containing this article was received at the Cornell University Library in October, 1910. Hence, they were not justified in designating their bulletin as they did by the title given above.

It will be shown by the writer (in his

What Motor Trucks Mean

IF you are not using motor trucks, we take it for granted that you do not understand the benefits to be derived from them. Possibly you have the wrong viewpoint—perhaps you have been making too many comparisons with the horses and not really investigating what the truck meant to you as a machine to perform certain work. The individual or firm that has a better delivery system has an advantage—the kind of business doesn't matter—service is appreciated universally. If The White Company can place in your hands a more efficient means of making deliveries, they have given you an opportunity of extending your field—of broadening the horizon of your product—of making good—where you had been unable to go before.

White Trucks Known for Performance

GO into any large city in the United States—ask the men who have the largest delivery problems, to see what they know about these White trucks. Almost regardless of whether they own them or not, you will find that they know their record for splendid performance. To the man about to invest in trucks, a list of White owners will appeal as almost a directory of the big business men. They have invested their good money in White trucks and their endorsement is the fact that they are continually increasing their equipment. No one buys and buys again the thing that fails to stand the test. We could tell you why—because it is all in the designing—in the building—in the care we take in the production of the truck. The important thing to you is that they do perform—that White trucks satisfy their owners—and, therefore, must be the kind that you want.

1500-lb. delivery wagons, 1½-ton, 3-ton and 5-ton trucks—all with a universal type of power plant.

Let us submit a solution of your delivery problem. It will entail no obligation

The White Company

838 East 79th Street, Cleveland, Ohio

Poultry Secrets Disclosed

We offer to all poultry raisers the essential knowledge and secret methods of many of the most successful poultrymen of America. As a rule these secrets have been guarded with extreme care, for it is on them that the great successes have been built. They have cost years of labor and thousands of dollars. They will cost YOU only a trifle and a few minutes to write us.

How We Obtained These Secrets

Michael K. Boyer, Associate Editor American Poultry Advocate, has had exceptional opportunities and the closest friendship with poultrymen all over the country. They have freely told him many of their most jealously treasured secrets, many others we have bought, and this scattered material, together with several of Mr. Boyer's own valued methods, has now been collected in book form. It must be clearly understood that **every secret printed has been obtained in an honorable way.**

"Poultry Secrets"

First published in 1908, this collection of the carefully guarded secrets of famous poultrymen created a sensation in poultry circles. It has run through thirteen editions, and is still selling at a lively rate

READ WHAT PURCHASERS SAY

I received Farm Journal and "Poultry Secrets," and am very much pleased with both. The secrets are worth their weight in gold. Why, I paid $5.00 for the sprouted oat method. You certainly give a fellow over his money's worth. Andrew F. C. Morey, Utica, N. Y.

I purchased a copy of "Poultry Secrets," and find many helpful ideas in it, especially Dr. Wood's Egg Hatching Secret.
Mrs. F. T. Darnell, Westfield, Ind.

By putting within our reach these "Poultry Secrets," you are doing a more philanthropic work than giving alms or endowing hospitals, for you make it possible for us to make both ends meet.
L. Boyce,
Milwaukee, Wis.

Received your book of "Poultry Secrets." It's an exceptionally instructive work, and worth $10 to any progressive poultryman. I would not care to take that for my copy if I could not get another.
Robt. F. Kingsland,
Montville, N. J.

The Farm Journal came to hand, and later "Poultry Secrets," also arrived, all of which I was very glad to receive and have been greatly interested in reading same, and think you are doing a glorious work in diffusing such valuable knowledge for so little money.
F. B. Meade,
Boston, Mass.

As to "Poultry Secrets," I will say I have lectured on the subject over the greater portion of the state for the past fifteen years and have about every book that is published on this subject in my library, and I consider the book of yours the most valuable I know, by far, for the general public.
L. A. Richardson,
Maine, Ill.

14th EDITION
NOW READY
Revised and up-to-date

Profusely illustrated, with many fine drawings and diagrams. 64 pages
Have you use for such a book? Then read the Offer below.

The **POULTRY SECRETS BOOK** is sold in combination with the Farm Journal, Philadelphia. The **FARM JOURNAL** is the standard paper for every one who lives in or near the country, or ever has, or ever expects to. A partial list of its poultry department, more valuable than most poultry papers: 33 years old, 750,000 subscribers and more. Goes everywhere. Clean, clever, cheerful, amusing, intensely practical. Cut to fit everybody, young or old, village, suburbs, or rural routes. Unlike any other paper and always has been.

AMERICAN POULTRY ADVOCATE, the great New York State paper, published at Syracuse, and full of good reading matter, is always welcomed by the subscriber. Now in its 19th year. Has come edited to be one of the best poultry papers published in the United States. We'll edited by recognized authorities on the subject of practical poultry raising. Has a guaranteed circulation of 45,000 copies per month.

SPECIAL OFFER For $1.00 (cash, money order or check) we will send prepaid the **Poultry Secrets Book** and the **Farm Journal** for two years and **American Poultry Advocate** two years, all for $1.00 (in Canada $1.00, foreign countries $2.00) if order is sent at once to

AMERICAN POULTRY ADVOCATE, 175 Hodgkins Block, Syracuse, N.Y.

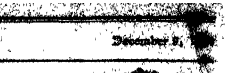
forthcoming bulletin) that the beneficial effect of legumes or non-legumes, was noted and recorded many years ago; in fact, empirical observations on this subject were recorded more than one hundred years ago in English books on agriculture. Hence, the writer does not claim that he was the first to observe this effect. Nor are Lyon and Bizzell justified in making this claim for themselves. It is the contention of the writer that he was the first to demonstrate in an exact and scientific way (by properly controlled pot experiments) that diffusion of nitrogen compounds, out of the roots of legumes takes place, and that these nitrogen compounds may diffuse through sandy soil and through porous earthenware, and may be absorbed by non-legumes separated from the legumes in this manner.
JACOB G. LIPMAN, Director.
New Jersey Agricultural College Experiment Station, New Brunswick, N. J.

Wooden Shoes

To the Editor of SCIENTIFIC AMERICAN.

In your issue of October 28th, 1911, under the caption of "Wooden Shoes," the United States Vice-Consul at Amsterdam, Holland, is made to say that Lancaster County, Nebraska, is a large importer of wooden shoes from Holland. For the benefit of your readers, and particularly the enlightenment of the Honorable Vice-Consul, we would like to have it understood that Nebraska is thoroughly civilized and we have the lowest percentage of illiterates of any State in the Union. The United States Custom House was opened in Lincoln twenty years ago, and a search of the records of importations fails to disclose a single shipment of wooden shoes for any firm in the State.

You might be interested in knowing that the largest wooden (shoe) sole factory in this country is located at Columbus, Nebraska, sixty miles north of Lincoln, and that the entire output is consumed in the territory lying east of Ohio and north of the Potomac River.
W. S. WHITTEN,
Secretary Lincoln Commercial Club.
Lincoln, Neb.



Lieut. Rambaldo—The End of a Promising Career

SOME months ago the SCIENTIFIC AMERICAN mentioned the daring project, conceived by Lieut. A. E. Rambaldo, of the Dutch navy, of exploring the interior of New Guinea by drifting over it in a balloon. This plan found many warm supporters in Germany, where it was chiefly promoted, but had at length to be given up, as the necessary funds were not forthcoming.

Recently news has been received that Rambaldo met an untimely death in Java on August 5th, while making a balloon voyage, in company with Lieut. van Steyn, also of the Dutch navy, from Soerabaia in the direction of Semarang. In attempting to make a landing in a forest, Rambaldo had climbed into the upper branches of a tree; a sudden upward movement of the balloon pitched him to the ground, while his companion was carried away in the lightened balloon. His lifeless body was recovered the following day. Van Steyn effected a safe landing.

Rambaldo, who was not yet thirty-two years old at the time of his death, was an aeronaut of the type that is common in Germany than elsewhere. He was a keen student of the new science of aerology, and spent many months in studying the methods of upper-air research at Lindenberg Observatory and at other aerological stations. Subsequently he made a long and valuable series of kite observations during a cruise to the West and East Indies on board the Dutch man-of-war "De Ruyter." Having been ordered to duty in Java, he founded an aeronautical society in that colony, and took an active part in inaugurating the aerological work of the Batavia Observatory, the brilliant results of which during the last few months have added much to our knowledge of the upper atmosphere.

At the time of his death he was planning to return to Europe to take a course in aviation, and had recently published in the German aeronautical press the outline of a project for introducing this art on an extensive scale in Java, for scientific and practical purposes.

The Dean removing scale from the tube of a return tubular boiler.

SCALE

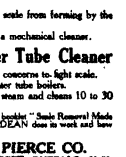
plays havoc with a boiler and digs deep into the coal pile.

And you can't prevent scale from forming by the use of chemicals.

You must remove it by a mechanical cleaner.

The Dean Boiler Tube Cleaner

is used by over 12,000 concerns to fight scale. It cleans fire tube or water tube boilers.



It is operated by air or steam and cleans 10 to 30 tubes an hour.

Suppose you write for our booklet "Scale Removal Made Easy," which tells you how the DEAN does its work and how it can save you money.

Little Things that Make a Big Winner

L. C. Smith & Bros. Typewriter

(BALL BEARING, LONG-WEARING)

Typebar ball-bearings made like a watch. Carriage, to move at a feather touch and stand at any point, unshakeable. Escapement, lightning swift, in its getaway from the operator's nimble fingers. Touch, smooth, sharp, with snappy response. Shift-key lightened to one-third ordinary pressure.

Careful, painstaking application to such fine details of construction have given you a typewriter that gets *big results* and does satisfactory work—all kinds of it—without a bit of fuss or needless effort.

Your stenographers will like the L. C. Smith & Bros. Typewriter because it enables them to do better work, do it easier, and do more of it. You'll want it, yourself, for the same reasons and also because, on account of the ball-bearings throughout, it keeps in better order and gives much longer service.

Send for "Another Decision by Experts" telling how the Savage Arms Company chose a typewriter equipment.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12572) S B. asks: If a meter were attached to the wire of a five-horse motor, and the current (500 volts) turned on for, say, one hour, running only single motor, would it use as much juice in one hour as if the motor were doing full five horses' work? A. If a five horse-power electric motor is run without load, it will only require the current to turn it which is able to overcome the friction of the parts of the motor. If full load is put upon the motor, it will then require five horse-power to turn it. This is exactly the same as any other machine, a grindstone, for instance. A boy can turn it swiftly when there is nothing grinding upon it, but if a man holds a scythe upon it, bearing down with all his force, even a man might not be able to keep the stone in motion. Power must be furnished to any machine in proportion to the work called for from the machine.

(12573) G W M asks: 1. What are the chemical elements found in the atmosphere? Is there any chemical change when subjected to heat? A. Atmospheric air is made up of 21 per cent of oxygen, 78 per cent of nitrogen, about 1 per cent of argon and a minute trace of helium, xenon, neon, krypton hydrogen. No chemical change is produced by simply heating the air to any moderate degree unless some other substance is present which can be burned with the oxygen. At the temperature of the electric arc the nitrogen and oxygen combine and form nitric and nitrous oxides. 2. How is commercial oxygen used in medical science, produced? A. Oxygen for industrial and medical purposes is made from chlorate of potash or from binoxide of sodium. The former is heated in a retort with manganese dioxide, and the latter is simply dropped into water.

(12574) E J L asks: Will it be too much bother to advise me the number of cubic feet in a perch of stone? The dictionary and printed authorities all seem to agree on 24¾, but masons here claim that there are only 16½. A. A "perch" of masonry is not a measure whose value is everywhere the same. It seems to be usually 16½ feet long and 1½ by 1 foot which would make it contain 24¾ cubic feet. It is often taken at 25 cubic feet. It has other values in different parts. If such peculiar measures could be dropped and our work measured in feet, yards, etc., it would greatly simplify matters.

(12575) J B C asks how to oxidize silver. A. 1. Add four or five thousandths ammonium sulphide or potassium sulphide to water at a temperature of 160 to 180 degrees Fahrenheit. When the articles are dipped into this solution an iridescent coating of silver sulphide is produced which, after a few seconds, turns blue black if allowed to remain in the bath. Remove, rinse, scratch brush and burnish when desired. 2. There are two distinct shades in use, one produced by a chloride which has a brownish tint, and the other by sulphur, which has a bluish-black tint. To produce the former it is only necessary to wash the article with a solution of sal ammoniac (ammonium chloride). 3. A much more beautiful tint may be obtained by employing a solution composed of equal parts of copper sulphate and ammonium chloride in vinegar (or dilute acetic acid). The fine black tint may be produced by a slightly warm solution of sodium or potassium sulphide. 4. Bromine, 5 gr.; potassium bromide, 5 dwt.; water, 10 oz.; boil the silver in this usually 2 to 5 minutes, then polish with rouge. 5. Dissolve sulphate of copper, 2 dwt.; nitrate of potash, 1 dwt.; ammonium chloride, 2 dwt.; in a little acetic acid. Warm the article and apply the solution with a camel's hair pencil and expose to the fumes of sulphur in a closed box. Parts not to be colored must be coated with wax. 6. Dip the clean silver article in a solution of sulphide of potassium (liver of sulphur), 2 dr. to 1 pt. of water. Heat this solution to a temperature of 170 degrees Fahrenheit. Immerse for a few seconds only, when the article becomes blue black. For a velvet black, dip the article, previous to oxidizing, in a solution of mercurous nitrate and water, and rinse. Then dip in the sulphide solution as above. For a brown shade, oxidize the potassium sulphide as above, then dip in a liquid composed of 10 parts of blue vitriol and 5 parts of sal ammoniac to 100 parts of vinegar. After oxidation, brush with a scratch brush very lightly, to brighten and variegate the surface. There are many other methods, among which will be found the following: 7. Expose to the vapor of chlorine. 8. Use a solution of equal parts of copper sulphate and ammonium chloride dissolved in vinegar.

Waterman's Ideal Fountain Pen

Always Acceptable

WATERMAN'S IDEAL is one of the very few gifts which the receiver can put right in pocket or purse for constant use. If everyone had the selecting of their own Christmas presents this is the kind that would be purchased. As a gift to *anyone*, or for yourself, there is not another article that shows better purchasing discretion than Waterman's Ideal Fountain Pen—it is a compliment to your taste.

This pen is made in a very wide range of sizes and styles in order that the pen technique of every writer may be individually suited. Your selection may be exchanged until satisfactory. Whether you buy a plain Waterman's Ideal or one studded with diamonds, the quality is of that same successful standard which the careful workmanship and Waterman patents have brought to continued perfection. This is the gift for people who are hard to suit.

NEW BOOKS, ETC.

THE UNITED STATES NAVY. A Handbook By Henry Williams, Naval Constructor U S. Navy New York. Henry Holt & Co , 1911 228 pp. Illustrated with numerous half-tone engravings and line cuts Price, $1.50

A naval constructor, above all men, is furnished for the task of telling the layman just the very things he wishes to know about the United States Navy For not only is he absolutely familiar with the construction of the ships from keel to fire control platform, but, due to his having spent several years at sea in perfecting himself for his profession he is thoroughly acquainted with the operation of these ships at sea and the routine life of the officers and men both ashore and afloat The author was prompted to write his book after answering many of the letters which came to the Department requesting information regarding the Navy The work is intended primarily for the information of persons having some interest in naval affairs—and Mr Williams has succeeded in writing a book which does not without being too technical The Handbook is written also with a view to supplying newspaper men with the information they so frequently apply for. Furthermore, the writer has had in view the desire of the friends of enlisted men from the interior States for information regarding the ships and the service The work has been well done It opens with a brief history of the Navy Then follow chapters on The Navy's Organization, The Navy's Personnel, The Man-of-War in Commission The Different Classes of Ships, A Description of the Equipment, etc., of Our Ships; High Explosives under which are treated mines, torpedoes, and aeroplanes, The Designing and Building of a Warship and the Drydock The work closes with a chapter on "The National Defense" in which the paramount importance of an adequate navy is clearly proved We give this work our hearty commendation

THE CORSICAN A Diary of Napoleon's Life in His Own Words By R M Johnston Boston and New York Houghton, Mifflin & Co 526 pp Price, $1 75

This book is to be welcomed as a distinct and valuable addition to the already enormous mass of biographical literature which deals with the life and character of Napoleon I In the endeavor to get a true perspective of that most extraordinary man of the eighteenth and nineteenth centuries, the historian and biographical writer have tried many points of view Perhaps, after all, the most effective method of putting one in touch with Napoleon is to let him speak for himself and this Mr Johnston has done by presenting the diary of Napoleon's life written in his own words A perusal of this work puts us in very intimate touch with the man himself, and one lays it down with the conviction that not the least among the qualifications of this exceedingly versatile genius was his ability to speak and write fiercely and with a great power of thunderation Commencing with his earliest days in the military schools, these extracts, judiciously chosen from his diaries, correspondence private and political, and proclamations to the army and the people, give a view of Napoleon quite devoid of distortion, which is inseparable from a partisan biography Perhaps the most marked impression left by this book is that of the intense humanity (as distinguished from the attributed lack of humaneness) of the great soldier He had his full share of the vanity and pettiness of human nature Never, until reading this work did we appreciate how largely Napoleon's genius was due to the fact that he was an engineer It was the practical and constructive in the man that won him lasting honor as the promoter of great public works, and carried him like a thunderbolt through the best armies of Europe

NAVAL STRATEGY Compared and Contrasted With the Principles and Practice of Military Operations on Land Lectures delivered at United States War College, Newport, R I, between the years 1887 and 1911 By Rear-Admiral A T Mahan, D.C.L., LL.D., United States Navy, author of "The Influence of Sea Power Upon History, 1660-1783," "The Influence of Sea Power Upon the French Revolution and Empire," "The Life of Nelson, the Embodiment of the Sea Power of Great Britain," etc Boston Little, Brown & Co., 1911 475 pp., 8vo Maps and plans Price, $3 50

The author of this work needs no introduction Always well known in the U. S Navy as an able lecturer on naval strategy, he was but little known abroad until the appearance of his great work, "The Influence of Sea Power upon History," which brought him international repute At once he was recognized abroad, and particularly in Great Britain, as the foremost authority on the great question of the importance of the command of the sea as the deciding factor in the struggles of the nations for supremacy.

This new work contains the results of almost a lifetime's study of the subject. Admiral Mahan has here prepared for book publication his lectures on naval strategy delivered at the Naval War College, Newport.

Admiral Mahan has given the historical

Amazing "DETROIT"

The "DETROIT" is the only engine that handles

methodical revision, developing them to include present conditions, and showing the conclusions to be drawn from the three most recent wars in which navies have borne an active part Japan and China in 1894, United States and Spain in 1898, and Japan and Russia in 1904 The contribution of each war to the subject was considerable, the last named being especially fruitful in furnishing examples of correct and incorrect naval strategy He shows the principal strategic strongholds existing to day, tells how the balance of power on the sea is maintained, and how it may be readjusted if Germany continues to increase her navy He takes up the subject of coast defenses both as protection to the country and as bases of supplies, remarks upon distribution of fleets and explains the changes and tactics made necessary by recent devices such as the wireless Defining naval strategy simply as "the proper use of means to attain ends," his analysis of the naval events of history from this view point brings a subject supposedly technical and difficult within the comprehension of the average reader.

COST-KEEPING FOR MANUFACTURING PLANTS. By Sterling H Bunnell, Ph B, M E New York D Appleton & Co., 1911 8vo, 232 pp Price, $3 net

To reach its highest efficiency a manufacturing plant must be watched as a doctor watches a patient It is the cost-keeping department that must point out the weak spots and indicate a remedy Without accurate knowledge of weak spots—that is, of instances where the cost of operations exceeds or approximates the selling price—remedies are mere guess work On the other hand, there is so much of complication and red tape about many cost-keeping systems that manufacturers hesitate to adopt them Mr Bunnell while avoiding in great measure the encumbrances incident to these systems, sacrifices nothing of efficiency He answers the debt of cost-acquisition in a general way, gives some valuable counsel on the introduction of an adequate system, and then proceeds to sustain and amplify the general principles by reducing them to practical application All the necessary accounting forms are drawn and their uses explained so that the routine of cost keeping may be established with the least amount of labor and worry, and may result in accurate and progressive knowledge of vital facts and details He clearly demonstrates that the efficiency of this department and the prosperity of a business are very closely related It would be hard to find a more enlightening or sensibly-written work on the subject

MOEDEBECK'S TASCHENBUCH FUR FLUG TECHNIKER UND LUFTSCHIFFER Berlin Verlag von M Krayn, 1911 920 p, 238 illustrations

It was in 1905 that the late Capt. Moedebeck issued his admirable aeronautic handbook When we consider that the dirigible at that time had hardly developed much beyond the experiments of Renard, and that Lilienthal alone had made any experiments in dynamic flight, we can readily understand how bold an undertaking Moedebeck's was Yet he carried through his scheme with good judgment and with such foresight that his book proved a boon when the dirigible really took its place in our daily lives In the first edition it was almost out of the question to devote much space to the flying machine for the simple reason that the flying machine as we know it did not exist In the second edition, issued in 1903, the remarkable performances of the dirigible still took up the major portion of the book Unfortunately Capt Moedebeck was not spared to revise this last edition that task has been intrusted to Prof Suering, of the Royal Meteorological Observatory at Potsdam That he has done it ably follows almost as a matter of course from his scientific standing As it now comes to us, the book is divided into the following chapters Gas (The Physical Properties of Gases and Technology of Gases); Atmospheric Physics, Aerological Observations, Kites and Parachutes, Balloon Technics, Navigating a Balloon, The Basis of Balloon Navigation, Practical Aspects of Balloon Navigation; The History of the Airship, Airship Construction Practical and Experimental, Navigation of Air Vehicles, Animal Flight, Gliding Flight, Technics of Flying; Engines for Airships and Flying Machines; Aerial Propellers, Society News, Tables

ARTISTIC HOMES. By Mabel Tuke Priestman. New York: A. C. McClurg & Co., 1911 8vo; 148 pp; illustrated Price, $2 net.

There is a steadily increasing appreciation of sensibly-planned and at the same time artistically satisfying houses that is encouraging to those of us who would have America surpass her older rivals in modes of taste as well as in business methods A home that is pleasing and restful to the eye contributes substantially to the contentment and education of mankind, and costs no more in the long run than many of the pinnacled and castellated atrocities we see around us. The growth of this appreciation of the truly beautiful and useful in home-making has been fostered to no small degree by such works as Mrs. Priest's "Artistic Homes," in which are described and pictured ideal dwellings visited by her in this country and in England, with concise statements of their cost and all the essential details of their construction.

"SWAN SAFETY" Fountpens for Christmas

They are made for continuous practical service and for that purpose are unexcelled. The construction is simplicity itself. There are no complicated parts to break or get out of order. The *"Ladder Feed"* and the *"Gold Top Feed"* furnish the exact amount of ink required, and automatically prevent flooding or skipping. The *"Screw Down Cap"* creates an ink tight chamber around the pen point and renders leaking or sweating absolutely impossible no matter in what position the pen is carried. The nib is of 14 karat gold, tipped with iridium and is *practically wear proof.*

Made in a variety of Sizes and Styles to suit all requirements.

For the man who wants a pen for practical work none can equal the "Swan Safety" A pen for every purpose. Nibs to suit the requirements of all styles of handwriting

For the *Bookkeeper* the Posting pen is unexcelled, and for ladies a large assortment in gold and silver is offered.

SWAN SAFETY FOUNTAIN PEN

may be depended on for years of satisfactory service and on account of its absolute reliability is indispensable to the owner.

FOR XMAS A *"SWAN"*

is always an ideal present and one that will recall pleasant memories of the donor for years to come. *Not a Toy* but a real help for busy men and women.

Prices, $2 50 and up, at all Stationers and Jewelers.

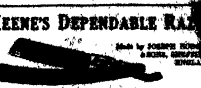
Huge Icebergs of the Southern Ocean

THE September *Monthly Meteorological Chart of the Indian Ocean*, published by the British Meteorological Office, contains a most useful account of the icebergs of the Southern Ocean, as reported by ships of all nationalities during the twenty years 1891-1910

In the southern hemisphere icebergs attain dimensions far exceeding that attained by similar formations in the northern hemisphere They may be fallen in with anywhere poleward of the parallel 30 deg S As many as 4,600 different bergs have been actually counted in a run of 2,000 miles; estimated heights of from 800 to 1,700 feet are not uncommon; and instances of bergs having lengths ranging from 6 to 82 miles are numerous

The most northern ice of the Southern Ocean, so far as the records from the beginning of the nineteenth century show, was a fragment of a berg sighted by the barque "Dochra" in 28 deg S., 26 deg W., in April, 1894 Icebergs are seldom sighted on the regular trade routes south of Australia, between the west coast of South America and the meridian of 80 deg W, and between the Falkland Islands and the east coast of South America

As to the abundance of icebergs in certain years, besides the case above mentioned of 4,500 bergs seen in one voyage, several other remarkable records are cited Thus in March, 1910, the "Prima" passed between 2,000 and 3,000 icebergs in two days, while steaming from 54 deg S 36 deg W to 47 deg S 38 deg W



The many flotillas of icebergs passed by vessels during the prolific period 1892 to 1897 included some of the loftiest on record In January, 1893, when 400 miles east of the Falklands the "Loch Torridon" passed many bergs varying in estimated height from 500 to 1,000 feet, and one of 1,500 feet The "Charles Racine" sighted a berg 1,500 feet high, midway of the Cape and Australia, in December, 1896, and one of the same height was sighted from the "Zinita, In November, 1904, about 120 miles south of the spot where that of the "Loch Torridon" was observed The loftiest berg on record, which had an estimated height of 1,700 feet above sea level, was passed by the bark "Emil Julius" in June, 1884, when in 44 deg S 49 deg E Since the beginning of 1889 there have been reported 39 instances of bergs from 800 to 1,700 feet in height, and 16 of these had an altitude of 1,000 feet So far back as 1840 a berg 1,000 feet high was sighted not far from the Cape of Good Hope

Since the beginning of 1884, 42 ships have reported bergs having estimated lengths of from 6 to 82 miles In May 1892, the "Strathdon," in 44 deg S 30 deg W., sailed 40 miles along the side of a berg This ice-island was 1,000 feet high In January, 1893, the "Loch Torridon," in 50 deg S 45 deg W., by sailing along the side of a berg determined its length to be 50 miles, and two months later, about 200 miles farther west, the bark "Æthelbert" is said to have passed one which was 82 miles long! Some of the extreme lengths reported in good faith are however, perhaps based on optical illusion; as a berg is sometimes unwittingly viewed through a gap between two other huge bergs, situated on either side of it, and overlapping its ends A case of this kind was observed during the "Challenger" expedition

A cubical iceberg will float with about one-ninth of its total height above the water It is not difficult, however, to imagine a lofty pinnacle berg having its base spread over a large area, and the under water depth comparatively insignificant In the majority of bergs the vertical heights of the submerged and visible portions seldom vary directly as the corresponding volumes.

Throughout the five months ended April, 1855, a book-shaped ice-island drifted about between the parallels of 40 deg. S and 44 deg S and the meridians of 20 deg W. and 28 deg. W The longer side stretched 60 miles, and the shorter parallel side 40 miles Between the two was a bay quite 40 miles from side to side at its widest part. Several ships entered this *cul-de-sac* under the erroneous supposition that there was an exit; and one was lost with passengers and crew. In 1892 and 1893 the "Urmodia," [illegible]

KEENE'S DEPENDABLE RA[illegible]

Made by JOSEPH RODGERS & SONS, CUTLERS TO HIS MAJESTY

MARK OF MERIT

This razor is absolutely perfect, both in shape and shaving qualities. Its fine quality of steel can possibly be purchased elsewhere, but never has 100 years of quality behind it. Each razor is personally passed, hardened and tempered individually, ensuring a perfect and even lasting shaving edge.

You simply cannot buy a better razor than this.

MONEY BACK GUARANTEE

The price of Keene's Dependable Razor is $2.50 and the value for your money in all to the keenest razor ever sold. Order one and if you don't find it the keenest razor you get, the money due for it will be sent back to you at once, no questions asked, and the razor kept, and we will return your money. This razor is warranted for 50 years.

Razor, price of razor, or if you prefer, send for our catalogue of Joseph Rodgers & Sons Razors, Pocket Knives and Scissors.

SCIENTIFIC AMERICAN

Annual Motor Number

Annual Motor Number

JANUARY MAGAZINE NUMBER
of the SCIENTIFIC AMERICAN
Issue of JANUARY 6th, 1912

In what respect do leading types of motor trucks for 1912 differ mechanically? How can the owner best protect his investment in motor trucks? What is the cost of operation as compared with horse-drawn trucks? Can truck chauffeurs be made of ordinary teamsters? These are vital questions to the intending purchaser of motor trucks, which are ably discussed in an article entitled **"Selection of a Motor Truck."**

The pleasure vehicle has now become so standardized that the **Riding Qualities of an Automobile** (the subject of an another article) now receive more thought than heretofore. The springs, the upholstering, the balance and hang of the body, all enter into the making up of a comfortable car. Other matters now of paramount importance to the motorist are the **Abolition of the Starting Crank, Lighting Systems,** which make automobiling at night safe and pleasurable, and the efforts to solve the **Tire Problem.** These form the subject of three special articles.

The Comparative Cost of Light and Heavy Cars is debated by a man who has made a painstaking comparison of every detail of his personal expenses in connection with the two types of cars.

The various phases of the automobile industry are discussed.

dale," and "Ranee" had a like experience At daybreak one morning the "Wasdale," northeast of the Falkland Islands, was discovered to be in a bay, of horseshoe shape, hollowed out of the side of an ice-island This bay was 20 miles long It varied in width from 10 miles at its broadest part to 4 miles at the entrance, and swarmed with large loose bergs

Recent Views on Road-Tarring

By Dr. Guglielminetti

SINCE the author made the first tests as to the tarring of macadamized and other roads about ten years ago, the question has been taken up in France by the Dust Prevention League, and the results were discussed at the International Congress of Roads held at Paris in 1908 and at the Brussels Congress of 1910 Since that time, it may be said that surface tarring has entered into standard practice As regards the question of hygiene, it appears that the desired end has already been reached, inasmuch as the amount of dust is much lessened The other point to be considered is that of cost All road engineers are agreed that tarring has the effect of lessening the wear of roads and increasing the life of the pavement, to say nothing of the reduction in street-cleaning expenses, including watering, mud removal and sweeping

But it was somewhat difficult up to the present to give any good figures for the economy realized on any given road In fact, it requires a certain time to estimate the economic results as to upkeep of a road where the nature and amount of traffic vary considerably from one year to another At present we are able to give some figures relating to the Avenue du Bois de Boulogne, a wide avenue leading out to the large park of the same name The figures are given by M Bret one of the city engineers This avenue is one of the finest in Europe, measuring 0.93 mile in length and 53 feet in width, and being bordered by a riding track and a footway The total surface is 25,466 square yards It was newly macadamized in September, 1906, and was first tarred in May, 1907 Since then it has not been macadamized, before the tarring was adopted it had to be relaid every three years The figures for expenses were drawn up for three and one half years preceding the tarring, then for four years afterwards Comparison of the figures shows that the annual saving up to the present is 11 cents per square yard, or about 25 per cent on the relaying and upkeep expenses alone not counting the economy on cleaning expenses It is noticed that the road was tarred only once in 1907, and after 1908 it was tarred twice a year, in spring and autumn The author, who is a leading official of the league, arranged with the city engineers so as to have tarring done in autumn in order to have a fresh surface for the winter traffic The result was striking, and in the spring following it was found that the surface was still in a very good state and the tar had remained on the greater part of the road surface, except in the middle where it had commenced to wear off

The economic question involved appears to be settled, and the life of the road may be considered as doubled, so that the tarring expenses are more than made up by the increased wear, as above shown On the other hand, the frequent relaying of ordinary roads, which requires two months, causes great disturbance in the traffic, while the tarring process needs but a few days in order to allow the tar to dry

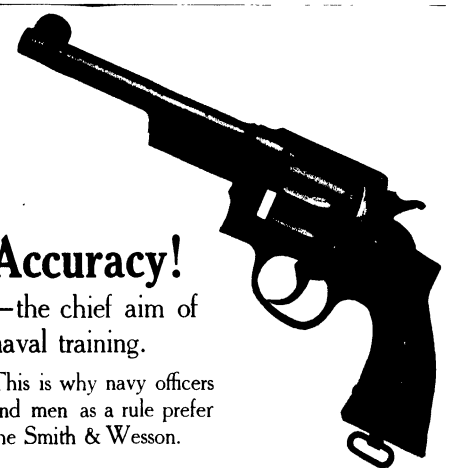
As regards the efficiency of the process in laying dust, the results are remarkable Before this, the avenue in question had to be frequently sprinkled in the hot season every two or three hours, but one washing per day is all that is now required, and no one complains of the dust Many thousands of automobiles per day pass over the avenue, so that at certain times, it used to be almost impossible to carry out the sprinkling, hence arose great clouds of dust and much discomfort and spoiling of clothes At present this has disappeared, and all agree as to the benefits of the tarring process

It would be too much to say that tarring could be carried out with equal advantage on all kinds of macadamized roads; for in the present case the traffic,

"No—Thank you! Pummo Soap for Mine."

ONCE tried, PUMMO SOAP is indispensable to mechanics and other workers who need a soap that will remove dirt, grease, grime and stains more thoroughly and quickly than ordinary toilet soaps. PUMMO will make the skin cleaner and whiter than any ordinary soap—in half the time.

PUMMO SOAP is composed of pure vegetable oils, glycerine and finely powdered Italian pumice. While its cleansing action is quick, searching, thorough, it leaves the skin soft, white, refreshed.



If your dealer does not have PUMMO, fill out and mail the coupon underneath and we will gladly send you free sample

Try the Wonderful Columbia Kerosene Engine at our Risk

Test it out on your own place for fifteen days. Give it the hardest engine test you can think of. Compare it with any other engine. If the Columbia doesn't develop more power at less cost, send it back quick. No conditions. We are willing to let you be the judge and jury. Kerosene (common lamp oil) is by far the cheapest fuel today. The price of gasoline is climbing all the time, while kerosene remains the same, and in the right engine, it lasts longer and produces more power per gallon than gasoline. You get ALL the power when you use a Columbia, because it is the right engine. It is the one really simple and perfect kerosene engine. It never balks when you need it most. It is always on the job.

Write for Particulars of Our Big Special Offer

We are going to double our output for next year. We can do it easily. It is just a matter of getting engine users to test the Columbia for themselves. So we are making a great special money saving offer on Columbia Kerosene Engines. This offer is liable to be withdrawn at any time, so write today for full particulars for it is a money saver you would hate to miss. Free Book No. 26 full of engine facts you need to know, sent free.

though dense, consists exclusively of light private vehicles, as the road is closed to heavy conveyances. In considering the question we must see what roads are best adapted to the tarring process. The failure properly to take into account this factor may explain the want of harmony between the city engineers having charge of streets and the engineers occupied with country roads, which was noticed at the Brussels Congress. The city engineers favored the suppression of macadamized roads in cities and considered that such should be paved with stone, wood, or asphalt as traffic increases. Opposed to this opinion were the other road engineers of nearly all the nations represented, and they showed the good results which road tarring had given, claiming that in towns having a lighter traffic this could be used to advantage. To conclude, a judicious choice should be made, and the tarring should not be done on macadamized roads where the heavy traffic required a re-laying every two years or even once a year. Such roads should certainly be paved, reserving the tarring for other kinds of ways.

The question, however, has been raised as to whether tarred roads have not a bad effect on the eyes of drivers and also upon trees and plants which border the routes. As to the harm done to the eyes, proof appears to be wanting, as the road from Paris to Versailles is entirely tarred, as well as the above-mentioned avenue, and we hear of no serious complaints for eight or nine years past, nor upon the roads in the south of France around Nice, where the dust is much greater. Laboratory experiments as to the effect of such dust on animals' eyes are of no avail, as any kind of dust is of course bad for the eyes.

Opinions are divided as to trees and flowers. Plant-growers claim that dust and tar vapors cause harm, while engineers think this is exaggerated. At Paris, the opinion is in favor of the tarring, in spite of any slight harm that may be done, owing to its other advantages. Dr. Griffon, in a paper read before the Academy, speaks first of tar vapors and then of dust. Vapor is bad for plant cells in laboratory tests, but this is not conclusive, as in reality such vapor must be very weak. He noticed that after the spreading and during the hardening of the yet unused roads, no effect was seen on the plants. As to dust, this has some effect on weak plants such as the begonia and others, which is not given from ordinary roads, but trees and shrubbery, also most plants and flowers, appear to show no harm. Leaves of trees may become brown or withered, but this often occurs in city streets, and is due to other causes. On the whole, his extensive inquiries in France and England lead him to favor the tarring.

No complaint apears to be heard in other countries. Since 1910, over 10,000 miles of road has been tarred in England, and the review *The Surveyor* does not note any serious injury to the eyes nor to plants. In Germany the same opinion appears to prevail, as also in Belgium. Owners of villas and gardens in the Riviera are among the most prominent members of the league, showing that they still favor the tarring. One reason for this latter opinion is that the plants in the south are of stronger growth, which leads to the opinion that the plants on Paris avenues should be changed. To bring out the question, the Prefect of the Seine department lately appointed a commission of leading experts. Shrubbery and various plants will be set out along tarred and untarred routes to compare results, and laboratory tests will be made upon any spots occurring in leaves. Attempts are made to purify tar and some samples are now produced which are much less harmful to plants and come near to Norway tar, which is quite inoffensive. It remains to be seen whether this will be economical or not. In any case, it seems evident that it is better to change the plants than to abandon the tarring, owing to its disadvantages. Dust also needs to be suppressed as much as possible. Even while no dust comes from the wear of the road itself, such is brought from the outside by wind or vehicles. The road should therefore be properly watered, and the author proposes to use one of the recent oil products which mix with the water, such as

Instructive Books

Gas, Gasoline and Oil Engines, Including Producer-Gas Plants

By GARDNER D. HISCOX, M. E. 6¼ x 9¼ inches. 476 pages. 412 illustrations. Cloth. *Price, $3.00.*

¶ This new revised and enlarged edition is a comprehensive and thoroughly up-to-date work, and treats fully on the construction, installation, operation and maintenance of gas, gasoline, kerosene and crude-petroleum engines. It treats on the gas, gasoline and oil engines as designed and manufactured in the United States, the stationary, marine and vehicle engines, their theory, care and running. Electric ignition by induction coils and jump sparks are fully explained and illustrated.

Practical Steam and Hot Water Heating and Ventilation

By ALFRED G. KING. 6½ x 9¼ inches. 402 pages. 304 illustrations. Cloth. *Price, $3.00.*

¶ A modern practical treatise, prepared for all engaged in the business of steam and hot-water heating and ventilation. It is an original and exhaustive work and describes all the principal systems of steam, hot-water, vacuum, vapor and vacuum-vapor heating, together with the new accelerated systems of hot-water circulation. It includes chapters on up-to-date methods of ventilation, fan or blower system of heating and ventilation, estimating, radiation and cost, and such other tables and information as make it an indispensable work for heating contractors, journeymen, steam fitters, steam fitter's apprentices, architects and builders.

Machine Shop Tools and Shop Practice

By WILLIAM H. VAN DERVOORT. M. E. 6½ x 9¼. 552 pages. 673 illustrations. Cloth. *Price, $3.00.*

¶ A very exhaustive and fully illustrated work, describing in every detail the construction, operation and manipulation of both hand and machine tools. It includes chapters on filing, fitting, and scraping surfaces; on drills, reamers, taps, and dies; the lathe and its tools; planers, shapers, and their tools; milling machines and cutters; gear cutters and gear cutting; drilling machines and drill work; grinding machines and their work; hardening and tempering; grazing, belting and transmission machinery; useful data.

Modern Steam Engineering in Theory and Practice

By GARDNER D. HISCOX, M.E. With a chapter on Electrical Engineering by Newton Harmon, E. E. 6¼ x 9¼ inches. 487 pages. 405 illustrations. Cloth. *Price, $3.00.*

¶ This is a complete and practical work for stationary engineers and firemen, dealing with the care and management of boilers, engines, pumps, superheated steam, refrigerating machinery, dynamos, motors, alternators, air compressors, and all other branches with which the modern engineer must be familiar. It fully describes and illustrates the properties and use of steam for the generation of power in the various types of engines in use. The slide valve, high-speed, Corliss, compound, multi-expansion engines and their valve gear, the DeLaval, Parsons, Curtis, and other turbines are included, and fully described and illustrated.

The Crusade Against the House Fly

ON July 24th, there was instituted in Washington, a most interesting crusade against the common house fly For several seasons one of the leading daily newspapers of the capital has been printing in display type the legend SWAT THE FLY, but this summer this same paper began its campaign in earnest Realizing that it is human nature to desire a pecuniary incentive for any public service, several hundred dollars in prizes were offered, one hundred dollars being the grand prize for the greatest number of flies killed, and many other prizes of lesser amounts representing first, second, third and fourth prizes, etc Only children under the age of sixteen were permitted to enter the fly-swatting contest Each contestant is furnished with a fly swatter, and paper boxes for the dead flies were distributed Each day the boxes containing the offerings of the workers are collected and the flies so exterminated are first counted at the Health Office, and then cremated The first five days of the campaign saw the leader in the contest with the proud record of 40,000 flies killed, with a long list of those who had more than 20,000 to their credit It is interesting to note that the children have organized themselves into squads and range over several blocks of territory, killing the flies in kitchens, grocery stores, stables and refuse heaps Even out of doors the fly has no peace but is kept busy dodging this veritable army of determined swatters Up to date, by actual count more than 2,000,000 of these pests have been exterminated, and the service performed in the interest of public health is enormous, when compared to the comparatively small outlay of money The only pity of it is that the campaign had to be financed entirely by private means, and that the municipality of the District of Columbia could not "raise the ante" and make the prizes attractive to grown persons as well It is not expected that in four weeks of the *Evening Star's* contest, Washington will be reduced to a state of absolute flyless ness, but that there will be a slump in next season's crop there is not the slightest shadow of doubt Considering the propagating possibilities of the fly, it would seem worth while for other cities to follow Washington's example in this regard and get the children started Think of the enormous slaughter of flies there would be on the East Side, for instance, if the myriads of kids, excited by the prospect of winning a handful of dollars, could be induced to "swat the fly."

Restoring Hardened Rubber.—Everyone is familiar with the very undesirable change to which rubber is subject on prolonged standing, such articles as rubber tires becoming hardened and brittle According to a note published in the *Motor World*, there is a simple remedy for this trouble, provided it has not gone too far This consists in immersing the article for a short time in an alkaline solution composed of one part of ammonia to two of water As an example of the efficiency of this process, an old bicycle tube which seemed beyond restoration was found quite fit for use after half an hour's immersion in such a solution, In explanation of the effect it is supposed that there is a tendency for acids to be formed in the rubber, and that these acids are neutralized by the alkaline solution On the strength of this, it is suggested that when tubes or other rubber articles are stored, a small quantity of quick lime or ammonium carbonate be included in the wrapping, though it could be kept from actual contact with the rubber. Periodic washing with ammonia and water is also suggested as a preventive.

Boston Street Lighting.—The total number of lamps on Boston's streets on January 10th of this year comprised 3,973 arc lamps, 1,206 tungsten incandescent, and 11,742 gas. During the year 1910 the cost of electric lighting was $408,900, that of gas lighting, $277,356. Naphtha lights were used in small numbers during the year at a cost of $1,832, but all of these have now been replaced with gas lights.—*Municipal Journal.*

Do you send Valuable Packages by Mail?

Government rates 150% higher than Hartford Mail Package Insurance

AS a business man whose business requires the use of the U. S. Mails for sending valuable merchandise have you ever considered the question of cutting down both the expense and the time of having your package registered by the Government? The **Hartford Fire Insurance Company** does both by its **Mail Package Insurance.** *For example:*

A package worth $5 00, weight 8 oz.		
P O Registration	10	
Postage, 1st class, 02 per oz	16	26
Hartford Coupon	02½	
Postage, 4th class, 01 per oz	08	10½
Saved by Hartford Mail Package Insurance		15½

BESIDES you don't have to go to the Post Office to register the package.

Send today for full information as to cost of certificate books and method of using.

The accepted style-fabric of universal wear for the man who cares—**OSWEGO SERGE**

A weave that serves well both tailor and wearer

No suit becomes you like a serge of blue. And of all ***good*** serges, ***OSWEGO SERGE*** is ***best*** of all. Whether this suit of yours be custom-made or ready-to-wear, it is your right to demand the cloth by name.

When you order, specify ***OSWEGO SERGE.***

This is what your money buys:

Sixteen ounces of pure wool to every yard; a blue, rich in tone, that favors the boy of six to the man of sixty; a fabric that has body, quality and feel; that holds its shape, drape and appearance. Not only a style-fabric—but economical, because of its price and durability.

American Woolen Company

Wm M Wood, President.

In order to be sure of the cloth when ordering a custom suit from your tailor, or a ready-to-wear suit from your clothier, insist on ***OSWEGO SERGE***—the cloth for now. Samples furnished on request

If unable to obtain OSWEGO SERGE, send us the name of your tailor or clothier, accompanied by money-order or check for quantity desired at $3.00 per yard, and we will see that you are supplied. (3½ yards to a suit.)

Order the Cloth as well as the Clothes

Mechanically the Abbott-Detroit IS RIGHT

ALTHOUGH a car may be a masterpiece of artistic beauty, a symposium of beautiful ideas, yet if it is not **right mechanically** it might as well be a piece of statuary or a bit of the landscape

It is its mechanical ability to propel itself that make it a thing of life—that makes it an automobile

Therefore the engineers of the Abbott-Detroit have seen to it that this—the most vital thing about a motor car has received the utmost care and consideration

Mechanically the Abbott-Detroit is right

No other car has ever endured the terrific punishment—over all sorts of roads—in all kinds of weather—under all changes of temperature and pressure—that the now famous Abbott Detroit "Bull Dog" has

This wonderful machine—a stock Abbott-Detroit 40 Touring Car which over a year ago was started on a 100,000 mile trip around the borders of the United States and through other countries of the Globe

It has now covered over 40,000 miles of this trip and is on its way to New York where it will be entered at the Annual Automobile Show It is still in perfect running order

We have just finished a book describing this wonderful trip which will be sent free upon request Send for our beautiful Art Catalogue which describes all the Abbott-Detroit models in detail

ABBOTT-DETROIT "44"		ABBOTT-DETROIT "30"	
Seven passenger Fore door Touring Car fully equipped (less Top Windshield Speedometer and Auxiliary Seats)	$1800	Roadster Touring Car fully equipped (less Top Windshield and Speedometer)	$1350
Fore door Semi Tonneau fully equipped (less Top Windshield and Speedometer)	$1775	Fore door Roadster fully equipped (less Top Windshield and Speedometer)	$1275
Fore door Limousine fully equipped	$3000	Colonial Coupe fully equipped	$2150
		Any model can be equipped with Dynamo equipment for Electric Lighting	$90
		Abbott Detroit Self Starter	$50

ABBOTT MOTOR COMPANY 613 WATERLOO STREET DETROIT, MICHIGAN

EXCEPTIONAL OPPORTUNITY TO VISIT

South America and Panama Canal

20,000 Mile Cruise, leaving New York Jan. 20, 1912

Calling at Port of Spain, Pernambuco, Santos, Buenos Aires (Across the Andes) Punta Arenas (through the Straits of Magellan), Valparaiso, Rio de Janeiro, Bahia, Para, Bridgetown, and a visit to the Panama Canal Duration of Cruise 80 Days—Cost $380 and up. Exceptional suite (two rooms) where Cruises De Luxe to the West Indies.

Five Delightful Cruises to the **WEST INDIES** Panama Canal, Venezuela and Bermuda

Leaving New York by the Palatial Twin Screw Steamers

S. S. Moltke (18,000 tons), 26 days, Jan. 28, Feb. 24, 1912, $180 and up
S. S. Hamburg (11,000 tons), 21 days, Feb. 10, March 7, 1912, $125 and up.
S. S. Moltke (18,000 tons), 16 days, March 26, 1912, $85 and up

Every luxury of travel, every refinement of service insured

GRAND ANNUAL EVENT

Around the World

November 1911, and February, 1912, by the Large Cruising Steamship, "VICTORIA LUISE" (10,500 tons)

GRAND ANNUAL CRUISE TO THE ORIENT

By the most palatial cruising steamer afloat, S. S. "VICTORIA LUISE" (10,500 tons)

Sailing from New York, January 30, 1912, on a 75-Day Cruise to Madeira, Spain, the Mediterranean and the Orient. Cost $325 and upward. The "Victoria Luise" is equipped with modern features providing every luxury and comfort on long cruises

Italy and Egypt

Special Trip by the superb transatlantic liner "Kaiserin Augusta Victoria," the largest and most luxurious steamer of the service. Leaves New York February 14, 1912, for Madeira, Gibraltar, Algiers, Villefranche, (Nice), Genoa, Naples and Port Said. Tour from Port Said, $165 and up. To or from all other ports, $115 and up.

Send for booklets giving information, etc.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

"Made in Germany"

TIME and time again the statement is made that Germany is the most scientific country in the world, scientific not simply in the sense that she has produced some of the most eminent chemists, physicists, biologists and physicians of modern times, but scientific in the fact that she has developed a system of commercially utilizing the immense amount of learning stored up in professorial brains. We in America have the reputation of being the most practical people in the world, of converting into dollars, by the most ingenious machinery ever devised, the unsurpassed natural resources of a continent. Yet if we compare the manner in which we have obtained the commercial respect of Europe, with the manner in which Germany has wrested from England a part of that export trade upon which the very life of England depends, we must concede that we have become prosperous largely through the bounty of Nature. With coal mines that must be worked at depths that tax all the resources of modern engineering, with forests that cannot compare even with the remnants of those that have been left to us by rapacious lumber companies with ore beds so limited in extent that iron must be imported in huge quantities from other countries, Germany has succeeded, in the short space of forty years, in becoming one of the most powerful industrial nations in the world.

And this she has accomplished not in an accidental, hap-hazard way, but consciously and systematically. The work that her generals accomplished in France in 1871 has been supplemented by the scientific generals of peace, by statesmen, university professors, doctors and chemists, who planned a policy of commercial development that would answer not simply the needs of to-day, but the needs of a generation to come. In 1876, the late Prof. Reuleaux came to this country as a German commissioner to the Philadelphia Exposition—one of the first opportunities seized by the newly formed empire to show its industrial strength. Reuleaux cast one despairing glance over the German exhibits, and promptly cabled to Bismarck "Our goods are cheap but wretched." That cablegram worked an industrial revolution. "Made in Germany" now means something more than mere cheapness.

How much real science is embodied in that catch phrase "Made in Germany," we intend to show in a series of articles which will appear in early issues of the SCIENTIFIC AMERICAN. To gather the information necessary for a series of articles so broad in scope, we sent our managing editor abroad to make a first-hand study of German commercial life and the part that science plays in governing cities and conducting a business.

Germany and German commerce are favorite topics of discussion these days, but there are phases of German commercial activity which, as we are to see, are only too little known to Americans. The Government's own relation to science, for example, as it is embodied in the work done by the Koenigliech Material-Pruefungsamt, near Berlin, is probably not fully appreciated in this country. Where, for example, would it be possible for a manufacturer of coats or of shoes to have his products scientifically analyzed by an impartial board of experts for a small sum of money and critically compared with the similar products of foreign and domestic manufacturers, all for the purpose that he may profit by the comparison, and with him German industry at large? Where, in all the world, is there a counterpart to the remarkable technologic museum at Munich, a public institution where a man may study chemistry, engineering, optics, physics, weaving, printing, with the aid of apparatus that he himself can set in motion? Where in America will we find the art of governing a city reduced to such a science, that it becomes possible for a municipality to operate its own railways, its own electric light plant, its own gas and water works, and to rent land, all with a profit? Where will we find a workman so scientifically cared for that his health, his hours of labor, his housing, his old age, are made subjects of the most paternal governmental concern? Where in America, with the isolated exception of the Chicago stockyards, will we find the by-products of an industry so completely utilized in building up vast industries that it is difficult sometimes to find a by-product to be converted into a useful article of manufacture?

We are not blind to the fact that, thanks to our youth and courage, Americans have created industries that overshadow in vastness anything that the old world has to offer; nor to the fact that it would be difficult, if not impossible, for a republic necessarily sensitive to every popular whim, to plan its own industrial and political development as scientifically as stolid monarchic Germany has done; nor lastly, to the fact that even enlightened Germans themselves are beginning to recognize that too much scientific education, too much scientific planning, too much governmental control, may clog the mind, and prevent a buoyant exercise of a man's powers. If there is little real daring in German enterprises, little of the adventurous buccaneering spirit that prompts an American to stake everything upon one cast of the industrial die, the reason is to be found not in any lack of courage in the German, but in his education and in his orderly mode of doing business. Scientific discoveries are rarely made by pouring the contents of one test tube into another at haphazard. Neither are many business enterprises successful simply because a manufacturer is willing to leap into the dark. The German takes no chances. His education has taught him the value of logical procedure in business as well as in the laboratory. We hope by publishing the articles in question to show the American manufacturer that a chemist or a physician, or a bacteriologist, may mean more in the upbuilding of his own business than a new piece of machinery, or a reduction in the scale of wages, or a cheapening of the rates of transportation. We Americans are beginning to realize that we must husband our natural resources that the days of reckless extravagance in the use of raw materials are over. In a few years, many a small manufacturer will wonder why it is that he has been forced into bankruptcy. He will attribute it, no doubt, to that keenness of competition which it now seems the purpose of our Government to restore to its medieval glory, and perhaps to his inability to cope with vast aggregations of capital. He will probably attribute his downfall not to the money of his rivals, but to his own inability to utilize his raw material with Teutonic and scientific completeness, to get the most out of a shovelful of coal and a handful of corn.

Germany owes her commercial success to her remarkable system of education, to the Government's co-operation with manufacturers, and lastly, to that army of men who watch the boiling of many colored liquids in glass retorts, whose eyes are glued to microscopes day in and day out, and who make everything according to a scientific method, whether it be a battleship or a tin whistle. The story of that success is a story of science, a story that we intend to tell in the SCIENTIFIC AMERICAN.

Physical Tests for Aviators

THE physical testing of engine drivers and other employees has long been an established policy of railroads. It has been recognized that the safety of hundreds of lives and of thousands of dollars worth of property may depend not only upon the skill and endurance of one man, but upon his physical fitness for his task.

Moreover, defects may exist in either sight or hearing of which the victim is himself more or less unconscious. Keenness of vision and sensitiveness of color perception, for example, are requisites in the case of engineers, switchmen, and others. Yet either may be impaired or congenitally defective, and the man never know it. A very remarkable instance of this is the case of the redoubtable General Lee Christmas, who is said to [illegible] driven by his inability to distinguish [illegible] fering colors to his picturesque and [illegible] career as a soldier of fortune through [illegible] ing disappointment and despair at [illegible] cut off from his cherished ambition of [illegible] a railroad engineer.

Thus far the chauffeurs of automobiles [illegible] been subjected to similar tests. In fact [illegible] of late that there has been a strong [illegible] for certified proof of a reasonable amount of mechanical knowledge and experience in [illegible] their part. Yet it is probable that many [illegible] and other accidents have been due to [illegible] infirmity of the driver.

But if a proper corporeal equipment is necessary to the motor-car driver or the engineer [illegible] one plane and in tolerably uniform [illegible] is absolutely essential to the air-pilot, [illegible] move in three dimensions and who is subject to the most varying conditions of temperature, [illegible], and air-pressure.

"Know thyself" becomes the very law of life to the aviator, and doubtless much of the appalling loss of life among aeroplanists might have been avoided had the too reckless birdmen been aware of their own physical defects and limitations. Given that the aeroplane has demonstrated its ability to carry a very considerable number of passengers—a Sommer biplane has recently carried six full-grown passengers on an hour's trip across country—public policy demands that a physician's certificate of physical soundness be required of applicants for a pilot's license.

A special study of this subject has been made recently by an Italian physician, who has reported some very interesting conclusions to the *Hygienic Gazette*. As a first requirement he observes that would-be pilots should have perfect functional action of the organs of the respiratory and circulatory systems, and of the nerve-centers, since all of these must be subjected to great exertion, strain, and disturbance.

Precision of movement of the limbs is highly important, and so is the ability to jump or leap with accuracy, a quality which depends not only on legaction, but on flexibility of trunk and clearness of sight. Resistance to shock should also be tested, as should keenness of vision for white and for colors.

Soundness of the auditory organs is a particularly vital matter. In the first place the hearing should be normal because upon this faculty especially devolves the noting of the proper and uninterrupted action of the motor. Also, a healthy state of the drum and middle ear, the free play of the chain of small bones, and an unobstructed condition of the upper air passages and the Eustachian tubes are indispensable conditions for the defense of the anatomic and functional integrity of the ear against the effects of the variation of the pressure of the air and of sundry meteorological agencies.

Most vital consideration of all, perhaps, is the integrity of the labyrinth of the internal ear, and especially of the three semi-circular canals. It has long been known that these canals, which are disposed in three separate planes, constitute a very delicate organ of equilibrium. The nerve-filaments they contain float in a liquid, any disturbance of whose level is at once conveyed to the brain. The peculiar gyrations of the waltzing mice of Japan are due to an abnormality of these canals.

In this connection Professor Nicedu-Semidel made some especially interesting observations, one to the effect that the sense of dynamic equilibrium is made more sensitive by exercise. In one instance an aspirant for a pilot's license showed marked errors and illusions of direction. On examination of his ears there were found traces of a previous purulent ear-trouble resulting in diminution of hearing and functional trouble of the semi-circular canals. When asked to walk in a straight line with his eyes shut he constantly bore to the right. This deflection was still more marked when walking in an arc of a circle, the circle enlarging at each turn if the trajectory was convex toward the right and decreasing correspondingly if toward the left. The observation of this case led the physician to formulate the circle test for the examination of the functional operation of the semi-circular canals in would-be pilots.

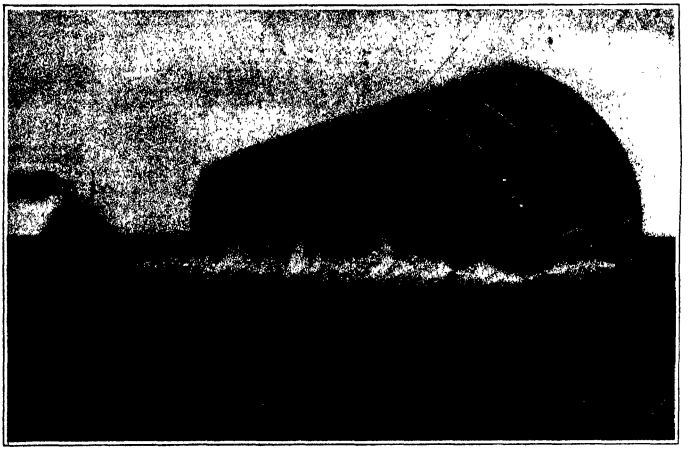
If the pilots of dirigibles and of floating balloons require less rigid tests in some respects, in others they are more liable to disturbance because of the greater heights at which they commonly move and because of the much longer duration of the flight. For them, heart and lung power are of greater import, skin sensitiveness should be considered, and gastric irritability may play a significant part in the diminution of strength and resistance and the general loss of staying power.

Self-dumping and Automatic Baling Scow

A New Type for Refuse Disposal and Harbor Construction

THE handling of waste materials and refuse from a great city is a vast problem When it is understood that New York city must dispose of at least 6,000,000 tons a year, or almost 20,000 tons per day, and that all or nearly all of this material must be transported to sea and dumped in not less than twelve fathoms of feet of water, which means a tow of from 22 to miles from the Battery, some idea will be gained of the magnitude of the undertaking

At the present time and for a number of years in the future there will be added to this a vast quantity of excavation resulting from subways



While a considerable portion of this material is transported within the harbor limits and used for solid fill in reclaiming waste land and shallow water, all of it will have to be transported on some kind of water craft. At the present time there are only two classes of vessels handling this material—the ordinary deck scow carrying the material upon the flat deck, from which it is unloaded either by hand or mechanical device, usually a grab bucket, and the so-called dump scow or bottom dumper, constructed with certain pockets or openings through the center which are closed by swinging doors in the bottom, retained in place by chains and mechanical devices. Into these pockets the material to be transported is delivered, and when the scow has been removed to sea or to some other part of the harbor where the material is to be used, the gates are opened and the material delivered through the bottom

While each of these devices is particularly fitted to do the work for which it was designed, neither can do the work of the other The unloading of the deck scow is a slow and tedious matter, either by hand or with mechanical device, and it is practically impossible to unload the dump scow otherwise than through the bottom. The dump scow is further handicapped by not being able to handle certain material, such as earth containing more than ten per cent of rock or mixed with boards, timbers or other refuse, which would either bridge across the openings when the bottom doors are opened or fail to leave the scow through the bottom, due to entanglement or a tendency to float The bottom dumper is further handicapped by the fact that if loaded in very cold weather, the bottom layers will freeze and the whole mass gradually assume such a condition as to be immovable until warm weather returns, or, as a last resort, by the use of dynamite, which will more often destroy the scow and render it useless without extensive repair

The reluctance of the bottom dumper to deliver all of its material through the bottom, has given rise to the practice of the towing captains called "bumping," which means, after the gates have been opened and the material refuses to leave, the tug is used as a battering ram, repeatedly butting into or bumping against the scow to dislodge the reluctant material. As the unloading usually occurs at night and far out at sea, often in heavy weather, and as the captain dislikes very much to return to port with half a cargo, the practice often results in discharging some of it through the hole made by the tug Besides the work of handling refuse from cities, there is a vast amount of work in handling rock for breakwaters in making new harbors and improving old ones

The craft herewith illustrated is intended to retain the deck-loading feature of the ordinary deck scow and to make possible a very much superior and more certain means of unloading In other words, the material is loaded on the deck in the ordinary manner and towed to any place within the harbor, and the material removed by mechanical means from the deck, or it may be towed to sea, when, by the manipulation of certain valves from the interior, it will turn completely over, depositing material positively and quickly and with every assurance that none of the load will be brought back

By referring to the drawings it will be seen that the scow is practically rectangular in cross-section, with rounded ends As it is intended to work either

NEW TYPE OF SELF-DUMPING SCOW

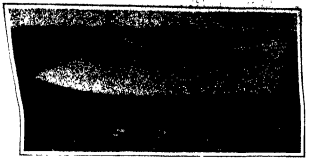
side up, the bow is required to be vertical The interior is divided by four longitudinal watertight bulkheads, one near each bow, extending from the bottom to the top of the scow, and two intermediate bulkheads extending between two false bottoms which are located from six to nine inches above the light draught water line of the scow

The scow is framed longitudinally with heavy trusses on four feet centers, well braced diagonally and secured vertically with tie rods The framing is of exceptionally heavy scantling throughout, well braced and stiffened with knees and breast hooks at bow and stern.

The larger drawing shows the operating machinery Considering the scow as loaded down to full load line with two feet freeboard, the operating wheel in the drum is turned, and through the transmission mechanism the valves are opened, admitting water to the space between the two false bottoms This water, being free to flow from side to side, gathers at one side and gradually lists the scow until it assumes the position shown in the third of the smaller engravings, where it has about reached the point of unstable equilibrium. The continued entrance of the water causes the scow to gradually turn up on edge, and finally fall over to the position shown in the fourth of the small engravings, finally coming to rest in the reversed position

There are valves or openings near the top and bottom of each compartment All these valves are opened at the same time the upper valves, when the scow is loaded, allowing the air to escape as the water enters at the lower openings

When the scow has reversed itself, the water which has entered will run out through the lower openings, due to the fact that the reserve buoyancy below the false bottom is sufficient to raise the bottom or deck six or eight inches above the light water line, after which the valves may be left open and closed at any time before the scow is reloaded

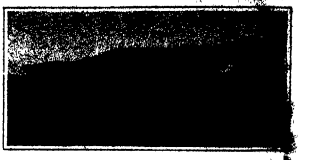


Perhaps the most novel feature of this scow is the arrangement by which it is possible for the operator to remain within the scow while it is being reversed, and it was of course, a matter of great interest as to how rapidly the scow would turn Repeated timing has shown that from the time the valves are opened until the scow assumes the vertical position on edge, fifteen seconds elapse

As the drum is 8 feet in diameter during this time the operator has to move one quarter of the revolution or 6 feet and while the remaining quarter turn is completed in from two to three seconds, the operator travels another 6 feet around the circumference of the drum, steadying himself by grasping the central spindle about which the operating wheel turns The whole turning movement is surprisingly slow and deliberate

Severe Hail-storms

THE destructive effects of large hailstones are most frequently experienced in subtropical regions at a considerable altitude above sea level Some of the most severe hailstorms have occurred in India At Belgium, December 22nd, 1884, 12 persons were killed, 78 injured, and 170 head of cattle and 560 sheep destroyed by hail In the State of Bihor, October 5th, 1893, the hail covered the ground to the depth of 4 to 6 feet, 6 persons were buried beneath it and perished, while 835 head of cattle were killed The most severe of these visitations occurred May 1st, 1888, when in the Moradabad district alone about 250 persons perished



In the United States one of the worst storms of this character occurred September 5th, 1898 in Nodoway County Missouri The path of the storm was about three miles wide and eighteen miles long, its greatest violence being felt over a region of four square miles east of Clarmont At one point in this region the fall of hail was so heavy that a drift unprotected by any artificial means remained lying on the ground for four weeks after the storm At the end of that time people in the neighborhood were found gathering the hail for the purpose of making ice cream During the storm cylindrical pieces of ice were picked up four inches long by about two and a half in diameter The growing corn was practically all destroyed; in a field of eighty acres only one stalk was left standing.

Noting the deflection of the plane.

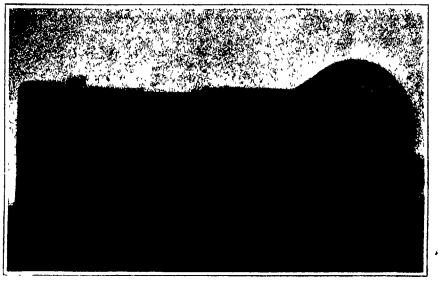
The Strength of an Aeroplane

A Family Hydroplane

A plane loaded with gravel.

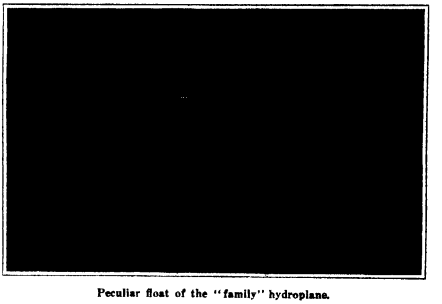
SINCE the successful launching on September 7th, 1911, of the hydro-aeroplane of the United States Navy, by sliding it down a wire, Mr Curtiss has given his attention to new experiments in aviation of no less interest

On October 2nd he made a test of the stresses in the stay wires of all the panels of the main sustaining surfaces of his standard biplane, in order to compare them with the stresses, determined by computation and by graphical construction To this end he turned the aeroplane upside down, supported it at its middle, and loaded the entire main planes with sand distributed in such manner as to produce in the guy wires the same stress as in ordinary flight



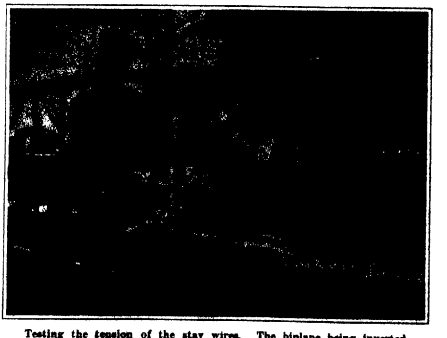
When subject to their full stress each wire was tested by means of a pair of tension tongs These look like ordinary blacksmith tongs except that each jaw is slitted so as to pass over the wire to be tested and grip it when the slits are closed by tightening screws When the jaws were thus attached to a wire, the handles of the tension tongs were drawn together just enough to cause the bit of wire between the jaws to lose its stress, and slacken The force on the long handles was then measured by a spring balance, which in fact caused them to exert the required stress, and the tension in the wire was found directly as the product of the force indicated by the spring balance multiplied by the ratio of the distances from the tongs pivot respectively to the spring balance and to the wire under test

It had been previously shown by analysis and by graphic statistics, that in a biplane whose surfaces have practically a uniform running load from center to either wing tip, as may be roughly assumed to be true in ordinary usage, the stress in the outwardly and upwardly sloping stay wires of the end panels, or wing tips, sustain but one-fourth as much tension as the corresponding wires in the second panels from the end, while those wires which slope outwardly and downwardly sustain no material tension due to pressure on the concave side of the wings, though they may be very severely strained when the machine is jolting over rough ground In the third section from either wing tip, known as the engine section, the tension in the guy wires and oblique stay rods is still greater, being more than five times the tension in the wires of the end panels



Though the test was made for practical rather than scientific purposes, the stresses were found to increase from the wing ends to the engine section approximately as indicated by theory It was observed also that each wire had a large factor of safety, ranging from about ten to thirty Mr Curtiss then added his weight of 150 pounds to one wing tip, while an assistant of equal weight stood on the other wing end The stress in the wires of the second panel was then doubled

Other tests were made on the ribs of the main planes It was noticed that they were sprung by the load of sand sufficiently to change the tension perceptibly in the fore-and-aft diagonal wires. Mr Curtiss had a panel of the main planes placed upside down with its spars resting on trestles placed transversely to the ribs When uniformly loaded with sand weighing ten times the usual pressure on the wings, these collapsed, due to breakage of the ribs From these various tests it was concluded that the weakest part can endure ten times the stress it usually has to sustain in ordinary flight



During the month of October Mr Curtiss developed a new type of hydro-aeroplane, intended for pleasure and sociability This has been called a "family hydro." The machine consists of a biplane mounted directly on a single boat of unusual size without intermediate framing so that the lower plane rests directly on top of the boat amidships The passengers will sit on the bow of the boat just before the lower plane The engine will be mounted just underneath the upper plane so as to allow the propeller on its crankshaft to swing freely without too near exposure to the bow of the boat and the spray thrown up when the latter is skimming the water rapidly. The usual floats at the wing ends will be used to preserve the lateral balance when the vessel rests quietly on the water or runs over its surface. The final goal is an aeroplane which can be manipulated as readily as a motor boat, which can be launched from smooth or rough water alike, and which, after a substantial voyage in the air, may be landed on earth or water with ease and security A novel wind-tube for studies in aerodynamics was developed in the Curtiss aeroplane factory during October, 1911, and found its first application in revealing the stream-lines about the wings and body of a small model of the new hydro-aeroplane. The wind-tube, which is but the model of a full-sized wind-tunnel to be built later, is shown in the photograph. It measures six feet in length by fifteen inches square in cross-section, and is provided with a glass door through which models can be introduced and studied in the air stream As usual the current of air is generated by an electric motor driving a suction fan or screw at one end of the tube, while at the other end is inserted a honeycomb structure for causing the air to flow in straight lines free from swirls and eddies The "honeycomb" in this case is a standard aeroplane radiator having cells four inches long by one-fourth inch square in cross-section. The air enters the tube through this straightener at a part of the room free from obstructions and well above the floor As a consequence it moves in a smooth current of uniform velocity. A fine silk thread suspended in the current shows a deviation of the stream-lines of but a small fraction of a degree to and fro from exact parallelism with the walls of the tube The speed of the air, tested when the motor was not perfectly steady, showed a diminution of nearly two per cent across the tube at the middle of the window, when explored from mid section to within less than two inches of the walls, but in the stratum extending from the walls inwardly 1.5 inch, a considerable variation of wind speed was observable, due no doubt to skin friction on the four feet of wall between the radiator and the section in question A cone was placed at the motor end of the tube to incase the 30-inch suction screw, and a like cone may be placed before the radiator, if thought advisable, to improve the flow of air.

Wind tube with radiator for straightening stream lines.

Peculiar float of the "family" hydroplane.

Testing the tension of the stay wires. The biplane being inverted and loaded with gravel.

This wind-tube is so simple and effective that it may be found serviceable to other aviation students who may wish to make like experiments. But of course it is desirable to have very much larger tubes, equipped with proportionately large radiators, since a small model may easily disturb the stream-lines as far as the walls of a small tube, and thus give different indications from those for freely flowing air. The radiator not only makes an efficient straightener, but also may serve to keep the air at any desired temperature, if a suitable fluid be made to course through it. This remark applies particularly to a wind-tube having a closed circulation of air.

Two methods are used by Mr. Curtiss to delineate the stream-lines of the air current flowing past any model inside the wind-tube. One is to attach a fine silk thread to a fine wire, and hold it at various points about the model; the

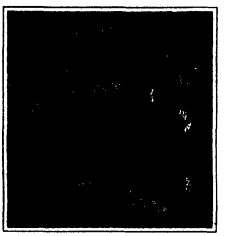
Curiosities of Science and Invention



Recovering a Current of 800 Amperes at 13,000 Volts

A paper recently read before the Schenectady Mid-year Convention of the American Institute of Electrical Engineers, D. Merriam discussed the problems of oil-break circuit breakers. The oil circuit breaker interrupts an electrical circuit in oil without producing abnormal disturbances in that circuit and also confines the destructive arc to a small volume, thereby preventing its spread to adjacent apparatus and enabling the oil circuit breaker to be safely placed in any convenient location on the switchboard or in the power station. Air break circuit breakers, owing to the large vicious arcs which they produce, are unsuited for general alternating current circuit breaking applications. The illustration herewith shows an arc drawn by one of these devices when opening a circuit carrying 800 amperes at 13,000 volts. This arc, one of many observed, was about 180 inches long and rose 140 inches in the air, while the same circuit ruptured in oil produced an arc only 9 inches long and with no external disturbance.

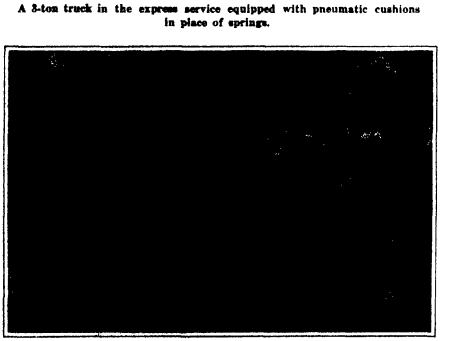
A 180-inch arc drawn out by an air switch.

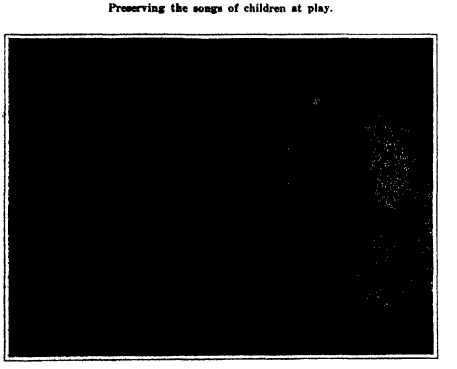
Getting standard time by wireless from the Eiffel Tower.

Pneumatic Spring for Automobiles

We illustrate herewith a pneumatic cushion which has with considerable success during the past year been used to take the place of springs in automobiles, and which is now being tested on the commercial vehicle. The cushions consist of rubber bulbs, each with an outlet through the neck at the top, connecting with a good-sized air reservoir. The cushions at the front have a separate air tank from those at the rear. A pressure of but 27 pounds is used in the front cushions, which are 8 inches in diameter, whereas 43 pounds to the square inch is the pressure used in the rear 10-inch cushions. This pressure is sufficient to support the weight of a 3½-ton express truck, fully loaded. In the future, a single bulb will be used in place of each spring, these bulbs being 9 inches in diameter in the front, and 12 inches at the rear. According to the superintendent of the express company which has been testing these cushions on one of its trucks for the past two months, the cushions absorb the road vibrations of the running gear and cause the wheels to cling to the ground, giving better traction. The result is twofold—a decided diminution of the wear and tear on the engine and transmission, and longer life of the tires because they do not bounce so much. The saving on the machinery and tires is estimated to be as much as twenty-five per cent in both cases. Another good point of the cushion spring is that it will not crystallize and break as steel springs frequently do. This is a decided advantage, especially with a commercial vehicle, where the breakage of a spring generally causes great delay.



A 3-ton truck in the express service equipped with pneumatic cushions in place of springs.



A Museum of Speech

For more than a year, a Parisian professor, Mr. Ponge, has been engaged in creating a very original museum, for the collection and preservation of records of the human voice under all of its manifestations. In this museum of speech there will be in addition to the original records, wax copies and microphotographs of the contour and relief of characteristic phonograms; also studies of the organs of speech as well as photographs of speech (Marage process).

With the help of these data, the museum of speech will make a phonetic chart of French speakers. Thanks to these files it will be possible to notice almost imperceptible differences between the same words in the *patois* of two neighboring villages, or of two successive generations. Just now Mr. Ponge is using the phonograph to preserve the children's songs and the cries of the street as well as the speeches of the great orators, the sermons of the celebrated preachers, the arguments of illustrious members of the bar, etc. One of the photographs shows him at work in a school among the children playing and singing a child's song. Another of our views shows him in the street recording the cry of an asparagus vendor. He has a fertile field for work among street criers. There is the hawker of straw goods, the mender of chairs, the china and porcelain merchant, the cask maker rolling his barrel as he goes along, the glazier and other small merchants whose "speech" he records for minute study.

Preserving the songs of children at play.

Recording the cry of an asparagus vendor.

Setting a Watch by Wireless Time Signals

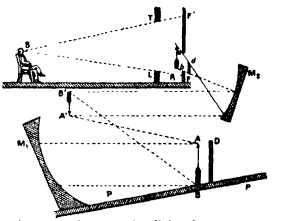
Now that time signals are being sent out from the Eiffel Tower periodically, amateur wireless telegraphers have seized the opportunity to set their watches by means of these signals. Obviously, this form of signal has its advantages over that of the time ball in common use here. The signal is sent out broadcast and any one may receive it in his own home, not only in Paris but in suburbs and neighboring towns. The receiving instruments of wireless telegraphy are very simple and inexpensive, and any boy can make them out of materials at hand, practically the only expense being that of a good telephone receiver. The accompanying photograph shows a rather more elaborate set of instruments than is absolutely necessary, and the operator, with telephone to his ear and watch in hand, is waiting for the signal from the Eiffel Tower. A system such as this should do much to set a standard of time over a large area at but little cost.

Mesmerizing Lobsters

Bizarre information may occasionally be gleaned from the most serious scientific literature. The title of the *Report of the Northumberland Sea Fisheries Committee for* 1910-11 suggests routine statistics on trawling and seining, sea temperatures and salinity, plankton and the like, hence it is somewhat disconcerting to find therein more or less valuable directions as to the best way to mesmerize lobsters. "The usual method (we quote from *Nature*) is to hold the lobster head down, with the claws arranged so as to form a support with the rostrum, and to stroke it rapidly with the tips of the fingers," i. e., to stroke the back of the carapace, or shell covering the crustacean's head and thorax. "In about a minute the lobster succumbs, and remains without movement in this position for a variable period. In order to see whether the reversed position, as driving the blood to the head, was essential, a lobster was treated in the horizontal attitude, and so successfully that it remained without movement for three hours. A Norway lobster subjected to a similar treatment was quiescent for fifty-minutes. A lobster can be put to sleep on its back. Other crustaceans are amenable to the same treatment. The crab goes to sleep usually in the tucked-up condition, and may be left in the natural position or on its back. They all recover when disturbed, but the recovery of the lobster appears to be quicker if the under surface of the cephalothorax is disturbed. Placed in sea water lobsters recover immediately, but in one such case a crab took ten minutes to come round completely."

The process is beautifully simple, and—such are the vicissitudes of life—one can never tell when the foregoing information might "come in handy."

Abstracts from Current Periodicals



Phases of Science as Other Editors See Them

Living Persons Represented on a Reduced Scale

THE idea of projecting on a screen living figures larger or smaller than life was realized more than a century ago, but the weakness of the available sources of light made the representation very imperfect Even the electric arc gives unsatisfactory results when lenses and a screen are employed, but by suppressing the screen and forming aerial images by means of concave mirrors, a very brilliant and realistic effect can be produced

An exhibition of this kind has been on view in Paris during the past year At one end of a darkened hall is a little stage with a curtain about five feet wide and three feet high The raising of the curtain reveals a "back drop" and side scenes of the usual type, and personages who move and speak in a very life like manner, but are only twelve or fifteen inches tall The following explanation of the trick, which we quote from *La Nature*, is conjectural, as the exhibitors refuse to give any information

The illusion is probably produced by two concave mirrors which are really above the floor, but are shown below the floor in the diagram, for the sake of clearness The real actor, indicated by the arrow *AB* stands before the mirror M_1, which forms a reduced and inverted aerial image of him at *A'B'*, and the second mirror M_2 forms a re-inverted and still further reduced aerial image at *ab*, on the stage, and in view of the spectator *S* The rays which form the image pass through an opening in the back scene, and the part of the scene which is thus cut out is painted on a larger scale, on a screen *D*, placed behind the actor *AB* This part of the scene and a portion of the floor *P* are thus projected with the actor's figure The actor's movements are necessarily restricted to a small area, but he can make gestures and dancing steps without getting out of range or focus The illumination, as well as the distances, dimensions and positions, requires very nice adjustment The actor and the projected scene *D* are necessarily illuminated by a powerful electric arc, while the back drop and side scenes of the little stage are lighted by rows of incandescent lamps, and the illumination must harmonize in order to produce a realistic effect These difficult problems have been solved with wonderful success

Apparatus for projecting living figures on a reduced scale.

Paintings Locked to the Wall

THE attempt occasioned by the recent theft of the "Mona Lisa" from the Louvre has drawn attention to the insufficient protection of paintings which are simply hung on the walls of our great art galleries, and can be detached by a twist of the hand on the part of a person more enterprising than scrupulous

The idea occurs naturally enough in some way to lock the paintings to the wall This is what the inventor of the device shown in our illustration herewith does

A horizontal bar of rectangular cross-section extends along the wall, its ends being placed in bearings which allow the bar to rotate so as to present either its narrow edge or its flat surface in plan view The paintings are provided with slotted ears, into which the horizontal locking bar can be inserted when in its "edgewise" position The bar is then turned flat and so locked by means of a lever (shown in Figs 2 and 3) The picture is then held firmly to the wall The device seems practicable enough, and should find extended use, though possibly to some tastes it may be objectionable at least for private residences, on esthetic grounds

Mining in the Stone Age

ALMOST interesting glimpse into prehistoric mining in the Stone Age has recently been revealed upon the opening of the Oural and Aram copper-cobalt mines in Spain according to the *American Antiquarian*

"In these ancient Spanish mines," states our contemporary, "the galleries and drifts do not open directly onto the mountain side. Instead they communicate with daylight by means of several vertical shafts or chimneys, a few meters in height. The purpose of this arrangement was, it has been suggested, to effect a better control over the slave-miners Perhaps, too, the purpose was to prevent wild animals from making their home in the mine along with the slaves

"Relics found both inside and outside the mine comprise bones, and various implements made of stone, bone, horn, fire-clay or of wood. Among the principal relics found on the interior were sixteen skeletons, two of them complete, stone hammers, picks made of horns of animals no longer known in Spain, stone needle, torch sticks, a bone knife, two wooden bowls, and, strangely enough, some coins. The skeletons which were found belong for the most part to miners suddenly killed in the midst of their labor, the hand still holds the hammer, and occasionally a skeleton is found under a fall of rock Other corpses met death in a cowering or crouching position

"All of the men must have been of extraordinary muscular development The heavier stone hammers which they used weighed as much as twenty or twenty-two pounds In spite of their muscular development, the majority of the miners were evidently of extremely slim build, for some of the galleries are literally polished by the rubbing of bones, and in these galleries, penetrating through the solid rock, a man of even small size can worm his way only with the greatest difficulty The skulls have the appearance of youthful individuals or of children, but, considering the differences in skull and brain development in those days as compared with to-day, this appearance may be deceptive

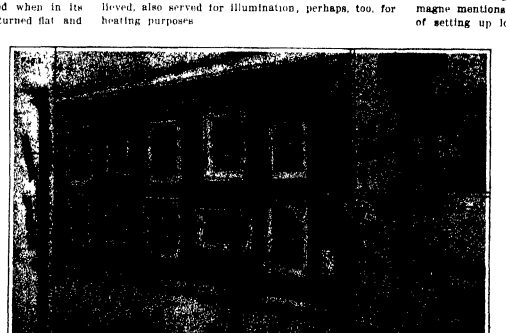
"The stone hammers, more or less polished, were often used by being held directly in the hand, without any sort of handle In some hammers a wooden helve is preserved and in a few a thong served as handle

"For illumination, the miners used sticks of wood four to eight inches long A ball of wet clay was rolled and slapped against the gallery wall Into this clay the miner stuck his little light Numbers of these wooden sticks or matches, the free end charred, are still preserved in place in their clay holders along the galleries There are also found some resinous branches or twigs, wrapped in hide, and the latter soaked with grease or with resin These, it is believed, also served for illumination, perhaps, too, for heating purposes

"Fire was used to splinter the rock, and to [illegible] it more friable and easier to attack. The clay [illegible] the vein walls was picked away by hand. Thou[illegible]ds of finger prints are still visible here; they show [illegible] that the thumb of the miner of these days was of t[illegible]endous size, almost double the length of the thu[illegible] of present-day workmen

"No props were used in the workings, which [illegible]not alone proves that they antedated the Romans, [illegible]n certain cases ore was extracted from the end o[illegible]gings into which to-day only a child would be [illegible]e to penetrate. Several galleries are so steep an[illegible]so slippery that any movement in them must have [illegible]n with the help of thongs fastened into the roof of [illegible]e gallery; in the-vertical stopes or raises there is [illegible]ually still preserved a stone ring into which such a thong was fastened

"Originally, the ores were smelted in shallow, scooped-out hollows in refractory clay. These primitive crucibles were about 8 inches in diameter, and with walls 1½ inch thick, fragments of them are preserved with ore, incompletely reduced, clinging to their sides Later they must have employed a more highly perfected smelting device, for pieces of quite homogeneous slag are found, this denotes the use for some continuous smelting apparatus."



Was Benjamin Franklin the First Inventor of the Lightning Conductor?

TO some it may seem almost a sacrilege to raise the question which appears at the head of this note. Perhaps it may not be amiss to say right at the outset that investigation of the evidence leads to a substantiation of the ordinarily accepted view which gives to Benjamin Franklin the honor of having invented the lightning conductor Nevertheless, it is interesting to note a number of passages in ancient literature and records which have by some been construed as anticipating the modern method of warding off the lightning This subject is discussed by an anonymous writer in *Die Welt der Technik*

Very soon after Franklin's invention became known, a French professor drew attention to ancient Tuscan and Roman instructions, which spoke of "calling down" lightning (*elicere*), and further pointed out that the ancient Romans had a regular rite for Jupiter *elicius* (Jupiter called down from heaven) It was argued, therefore, that the Tuscans and Romans knew, even at that early period, of the possibility of drawing down the lightning from the clouds The Celtic nations also were in the habit of sticking their swords in the earth with the point upward, near springs, on the approach of a thunder storm, as a protection against lightning The Persian King, Artaxerxes, was acquainted with the power of iron to attract lightning Again, Josephus Flavius, in describing the great temple of Herod in Jerusalem, states that the roof was studded with an army of golden points, and that a similar arrangement was found on the earlier temples of Solomon and Zerubbabel It is stated that none of these temples, in spite of their location upon an altitude, was ever struck by the lightning Coming down to the Middle Ages, it is noted that an edict of Charlemagne mentions that the peasants were in the habit of setting up long pointed pole in the ground on the approach of a storm, and in a sermon of St. Bernardinus of Siena it is mentioned that sailors would bind a sword with its point directed upward to the mast of their vessel on the approach of a storm

Apparently a very good case could be made against Franklin. Dr. Hennig, however, puts down all instances of this kind to pure superstition. The idea was to frighten away the storm demons by means of the upwardly-directed swords Among uncivilized peoples it is a common custom to threaten approaching storms by the din of arms, and the ancient Gauls and Romans would shoot arrows into the gathering storm clouds, to ward off the hostile powers of the weather.

As regards the golden points upon the temple at Jerusalem and other places, Josephus himself tells us that the purpose of these points was to keep off the birds.

From London Illustrated News

Locking the stable after the horse is gone.—The theft of the "Mona Lisa" has inspired this invention.

Engineering

...n the "Maine."—The work of uncovering the "Maine" is completed, and the report of the engineers and ... Board who made the investigation has been ... to the Secretary. In the opinion of the Board ... amination of the bottom of the ship in the region ... explosion presents evidence of a primary ex... ... external to the ship, and in all the main feat... the recent investigations have fully corroborated ... report of the Naval Board of Inquiry, made at the ... of the disaster.

...monument to Fitch.—In connection with the River ...ntennial Celebration, recently held in Pittsburgh, ...ere has been a movement to give a long-delayed but ...ell-deserved tribute to the work done by that inter...sting but very erratic character, John Fitch, in pro...moting the early development of the steamboat. Fitch ...as a typical American inventor, with all of his char...acteristic faith and perseverance His boat was the ...st to run on a regular schedule, carrying passengers ...This is a fact which cannot be disputed A newly-or...anized chapter of the Daughters of the American Rev...olution will be named in Fitch's honor and will erect a ...suitable monument to his memory

Lignite Briquette Experiments.—The Bureau of Mines, realizing the value of the vast deposits of lignite which exists in several western States and particularly in North and South Dakota, Montana and Texas, recently obtained from Germany a powerful briquetting machine, which is being used to determine the suitability of American lignites for the manufacture of briquettes The experimental work so far done has shown that lignite can be made into satisfactory briquettes at a cost that renders the manufacture commercially profitable The extended use of lignite briquettes would serve as an important factor in the conservation of our supplies of coal

The Hell Gate Bridge.—The letting of the contract for the imposing Hell Gate railroad bridge, which will serve to connect Long Island with the mainland at a point near the Harlem River, marks the beginning of work on the most imposing structure of its kind in this country, and the longest bridge of its type in existence. Its dominating feature will be a massive arch bridge of one thousand feet span, carrying four tracks capable of accommodating the heaviest railroad freight traffic The total length of the bridge, including approaches, will be three miles In the steel arch bridge alone there will be 18,000 tons of steel, and there will be a total of 70,000 tons in the whole structure.

The Panama Canal Fortifications.—With the exception of one of the fortifications at the Atlantic terminus, the defensive works which are being constructed at the Panama Canal will be named in honor of soldiers conspicuous in the Civil War. One of the Atlantic works will be called Fort De Lesseps The sea-coast fort at the Pacific terminus will be known as Fort Grant, and its batteries will bear names of division commanders of the northern army The sea-coast forts of the Atlantic terminus will be known as Fort Sherman, Fort Randolph, and Fort De Lesseps, and the batteries of Fort Sherman will be named after division commanders who served under General Sherman The batteries of the other two forts will bear the names of artillery officers who distinguished themselves in the war

Improving the Port of Para.—Although Para, the commercial metropolis of the Amazon valley and the greatest rubber-exporting center of the world, has long enjoyed an immense trade, this has been seriously hampered by two circumstances, viz., poor harbor facilities and the unhealthfulness of the town Recently the Brazilian government has taken seriously in hand the improvement of the harbor, and has nearly completed works the total cost of which will amount to about $39,000,000. Whereas formerly large vessels, owing to the shallowness of the water, were obliged to lie some miles from the quays, a considerable part of the new quay wall will have a depth alongside of from 30 to 32½ feet. Docks, ship-railways, metallic warehouses, electric cranes, and buildings for the customs, postoffice and national telegraph are included among the improvements. Meanwhile the state of Para is endeavoring to improve the hygienic conditions of the city, and especially to eliminate the particular type of mosquito which is the carrier of yellow fever.

Electricity

Street Car Telephones.—In order to avoid needless opening of car doors in winter weather, the street cars of Chicago are to be equipped with annunciator horns set at the four corners of the car in the ceiling, and connected with a telephone on the rear platform, by which the conductor may announce the streets

Wireless Messages to Flichner.—According to *Petermanns Mitteilungen*, wireless communication is likely to be established between the Argentine wireless station on New Year Island (near Cape Horn) and the "Deutschland," the vessel of Lieut Flichner's antarctic expedition, after the latter reaches the barrier ice and Weddell Sea.

Wireless Lighthouse Signals.—The new lighthouse at Ouessant, on the Channel coast of France, is noteworthy not only for its height of 120 feet and its powerful light, but also for the wireless signals which it is to send out The new apparatus is designed to give vibratory wireless waves so as to produce musical signals in the well-known way Two different notes, *do* and *sol* are used here, and they will be repeated at regular intervals so that such signals can be easily recognized by vessels at sea Following this, other stations of the kind are to be erected along the Channel

Cairo-Heliopolis Electric Line.—The new electric traction line running from Cairo to Heliopolis, Egypt, is laid out in two sections, the first lying between Boulac and Limoun Bridge and the second running from here to the second oasis The line is built on narrow gage (3 feet 3 inches) and runs trains made up of motor cars Each of the cars is fitted with four motors of the 50 horse-power Jeumont type, of French build, running on overhead trolley wire For this latter the voltage varies between 500 and 700 volts according to the section of road

Limited Current for Small Consumers.—The electric lighting station of Bremen, Germany has adopted a method for the sale of current by which it hopes to reach small consumers and induce them to abandon oil lighting For instance a workman's family living in a small lodging can make a yearly subscription for current to the amount of three 16 candle-power lamps per day, and for this he pays about the same price as for oil He is entitled to the use of the lamps continually, but more than this number cannot be turned on, as a current limiter prevents this However, nothing prevents wiring the quarters for a larger number of lamps, provided not more than the stated number are turned on at a time.

The Cost of Ultra-violet Sterilization of Waters.—A report has recently been made by Grimm and Wedert on the cost of sterilizing water by means of ultra-violet rays produced in a quartz lamp The cost for 50,000 hours' work was, for the quartz lamp $50 resistance $11, new burners $600, current $1,100, sundries $14, or a total of $1,775 This outlay represents the cost of sterilizing 5,000,000 gallons of water, or about one cent for 30 gallons The cost of complete sterilization is relatively much greater than that of partial sterilization By sterilizing the water within 99 per cent complete, the cost can be reduced to 90 gallons for one cent As compared with this the ozone system of sterilization would cost half as much, and ordinary filtering one-tenth as much

Federal Electric Railroads in Switzerland.—In Switzerland the question has been agitated for some time as to the best method to use for changing over the Federal railroads to electric traction, and a commission was appointed to look into the matter The commission recently issued its report and in this it concludes in favor of electric locomotives running on the single-phase system with 15,000 volts on the overhead wire Direct current is not favored, even though it takes less power, on account of the drawbacks it presents, first cost among others It is estimated that the expense of transforming all the Federal lines will reach $15,000,000, but there will be 10 per cent economy realized in operating the railroads The Swiss government has already allotted credits for purchasing a number of falls so as to erect electric plants for supplying the current

Electric Railroad from Genoa to Busalla.—A successful electric railroad is now running in the north of Italy from Genoa to Busalla, under control of the government. Genoa sends coal to all the northern region including Milan and Turin. A steam railroad ran across the mountains for this purpose, but the new electric road will be much superior It has heavy gradients and numerous tunnels, and uses heavy electric locomotives designed after the Simplon and Vaitellina types. Current is taken from a 3,000-volt line, working on the three-phase system The locomotives are designed to draw a 400-ton train upon 3.5 per cent grades at 25 miles an hour, and have 65 tons adhesion weight. The four axles of the locomotives are coupled by bar and crank and are driven from two 750 horse-power motors.

Science

Prehistoric Nursing Bottles.—According to recent discoveries it appears that nursing bottles were used even in prehistoric times This is true at least for the age of polished stone, inasmuch as a French archæologist, M Nicaise, when exploring a neolithic funerary deposit, found a small clay nursing bottle, and this was quite intact This is not the only specimen of the kind which comes from early ages Among others are the specimens found in the Gaulish burial places of Jonchery and more recently in the Gallo-Roman arena of Paris This latter, it will be remembered, was uncovered within a comparatively late period

The Genetic Congress.—The Fourth International Genetic Congress, recently held at Paris, was occupied mainly with the crossing of breeds in plants and the resulting hybrids which are obtained Outside of the great scientific interest which is involved, the question has a very practical bearing For instance M Soloman made experiments upon the crossing of potatoes for six years past, and hopes to produce a variety which will be able to resist the rotting disease The question of hybrids in connection with many kinds of plants such as peas, tobacco, cloves and others formed the object of the papers read at the congress

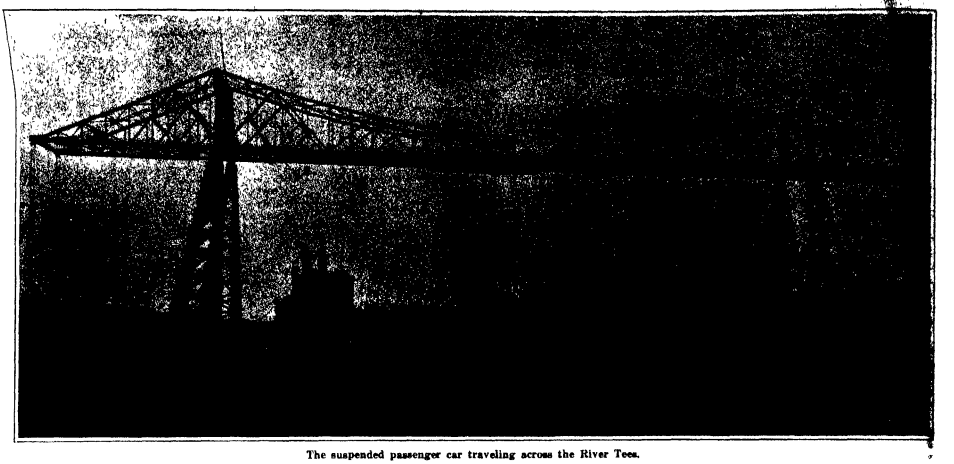
A New Comet.—A cablegram has been received at Harvard College Observatory from Prof Kobold at Kiel, stating that a comet was discovered by Schaumasse giving the following position

1911 Nov 30 6491 Greenwich Mean Time, R A 13h 12m 12s Dec +5 deg 51m

Daily motion R A 3m 32s, Dec —13m

The comet is visible in a small telescope A late cablegram from Kiel states that Schaumasse's comet was observed by Brashrock at Ucle in the following position

1911 Dec 4 7482 Greenwich Mean Time, R A 13h 26m 25.78 Dec 4 4 deg 57m, 05s



Sterilized Post Holes.—An engineer in Budapest has invented a process for the preservation of wood which bids fair to be of much economic importance The process is intended to be applied to wood used in outdoor construction, such as railroad ties, telegraph poles fences, palisades, and the like It consists in a sterilization of the surrounding soil by means of a liquid poured into the hole in the earth before the post or tie is planted The liquid is composed of chemicals which effectually destroy all insect life and all cryptogamous vegetation in the surrounding earth According to *La Revue* this prevents the rotting of the wood without the necessity of treating it with creosote, so that both time and expense is saved in many cases

Conversing With Animals.—A certain Charles Kellogg, of California, has appeared at Cambridge with the object of convincing the Harvard faculty of his ability to talk with animals His life has been spent among the Sierra Nevadas, and his studies include the vocal sounds made by bears, squirrels, lizards, rattlesnakes and crickets Indeed, he claims proficiency in fifteen animal languages He has a peculiar palate with no tonsils, and entirely lacks the cord connecting the teeth with the lips To these peculiarities he partly ascribes the ease with which he imitates the sounds of insects and animals Some of his observations and ideas are at least interesting, if not convincing

Excavations at Delphi.—The French School of Athens has been making some interesting excavations at Delphi, bearing upon four main points, the Temple of Hera, the valley and basin of the Ispous, the gymnasium and the theater quarter More than 200 vases were found in the basement of the Temple, dating from the 7th to the 6th century B C Some blue ware of an unusual kind was found here, also a fine series of terra cotta busts of the goddess Hera The plan of the gymnasium is now recognized, and some good stone inscriptions come from this spot To the west of the basin which collects the water of the Ispous torrent are the ruins of a small sanctuary which appear to date from the early history of Delphi

The Weight of Various Brains.—While the weight of the individual brain in each particular species, as compared with that of the entire system, may be said to have some bearing on the intelligence of the individual, there is no fixed proportion between the weight of the brain and the total weight of the body as between one species and another, as is shown by the following table

	Grammes	Average Ounces	Proportion	Per Cent
Elephant	4,660	16 44	1/459	0 23
Whale	2,490	8 78	1/25000	0 04
Man	1,400	4 94	1 42	2 38
Horse	500	1 76	1/534	0 19
Gorilla	425	1 50	1/213	0 47
Orang outang	400	1 41	1/134	0 75
Sheep	133	0 47	1/377	0 27
Dog	105	0.37	1/200	0 50
Pigeon			1/150	0.67

A Suspended Ferry

By F. C. Coleman

A NEW transporter bridge, which has been under construction for the past three years over the River Tees, one of the great industrial waterways of North-Eastern England, was formally opened for traffic by H R H Prince Arthur of Connaught on October 17th Hitherto communication between the thriving town of Middlesbrough and the industrial area on the north side of the river has been maintained by means of a municipal ferryboat service, but, during recent years, this method of transport has proved both inadequate and inconvenient Consideration has been given at various times to projects for a tunnel under the river, a suspension bridge, an ordinary swing bridge and also a rolling lift bridge In the case of a busy river like the Tees it is essential that any means adopted for accommodating the cross traffic should interfere as little as possible with the conduct of the up-and-down stream traffic and if no other objections existed there would be no doubt but that a tunnel or high level bridge would have afforded the best means for attaining this end But both the tunnel and the high level bridge, independently of high cost, would have involved the difficulties of approaches and in the case of a high-level bridge, this would, in a flat district like that of Middlesbrough, form a practically insurmountable obstacle, so long as the bridge was utilized by the traffic passing over it in the ordinary way Accordingly, in 1906, the Middlesbrough Corporation decided to replace the ferries by a transporter bridge

The Tees transporter bridge consists of two groups of piers erected on either bank of the river on masonry foundations and connected by a pair of lattice-type girders of 570 feet span with depths varying from 65 feet over the towers to 21 feet at the centers The underside of these girders is 160 feet above high water mark The girders on the lower flange each carry two lines of rails and are placed at a distance of 35 feet from center to center On the four lines of rails there is supported a traveling platform from which a traveling car, 44 feet by 39 feet, is suspended This car is provided with passenger cabins on each side, and its floor is level with the roadway on each side

Passenger car approaching the Middlesbrough side.

of the river Accommodation will be found for about 600 passengers and six road vehicles As the upper platform travels across the high-level girders the car is carried across the river between the landing places, the hauling to and fro of the traveling platform being effected by an endless ropeway The ends of this rope are fixed on a winch placed on the south side of the river and driven by two 60 H P. Westinghouse motors The journey from shore to shore will be accomplished in less than two minutes The working of the car will, generally be controlled from the pilot house placed on the top of the passenger cabin on the suspended platform, but in case of emergency it can also be worked from the winch house, distant about 150 feet from the main tower of the bridge on the Middlesbrough side of the river. One motor will, it is anticipated, be more than sufficient to propel the car, even in the most severe gale

The main girders are of the braced cantilever type and the extremities of the main span are anchored and secured to concrete anchorage blocks on each bank of the river by 16 wire ropes embedded in concrete, each rope being capable of withstanding a breaking strain of 300 tons. Owing to the unfavorable strata the main towers on the Port Clarence side have been distanced 130 feet from the shore and approach is therefore made by a lattice girder bridge. On the Port Clarence side the foundations were carried down to 90 feet below high water of spring tide, and on the Middlesbrough side to a depth of 70 feet. The caisson foundations are filled up solidly with concrete, and 10,000 cubic yards of concrete were used in these foundations and in the retaining walls supporting the same. After the caissons had been sunk and the steel towers sunk, the erection of the main girders proceeded simultaneously toward the land arm and over the river on the cantilever system. As the steel arms from each side of the river approached one another careful measurements as to levels and line had to be taken from time to time so as to insure an exact meeting in the center. As soon as they were within 100 feet of one another, exact dimensions were taken and after due allowance had been made for the proper measurements the closing lengths of the steel work that were required to fill in the gap were completed at the contractors' works and forwarded to the site. Aided by favorable weather conditions, the 100 feet of closing lengths was erected in position in sixteen hours, the work coming together perfectly as to line and level. The temperature at the time of closing was 58 deg. Fahr. The height of the towers above high water is about 250 feet, so that the bulk of this work was carried out at a height of about 200 feet.

[illegible]al stairways on one [illegible] two towers of each [illegible]ent afford access to the main platform of the bridge and this passageway is specially illustrated in one of the photographs. The total length of the bridge and approach span is 850 feet, the length of each cantilever girder overhanging on the landward side of the towers is 150 feet, and the extreme height of the bridge above high water to the top of the center of the towers (i. e., to the top of the main posts of the cantilever girders) is 325 feet The base girders, on which the towers are built, have a length of 98 feet, a depth of 16 feet, and a weight of 1163 tons. The total amount of steelwork in the bridge is 2,600 tons and there are 600 tons of steelwork in the caisson foundations. The total cost of the works and approaches, including buildings and all auxiliary work in connection with the structure, is estimated to be about $408,660

The boulevard across the main girder of the bridge, reached by spiral stairways in the towers.

The Rabbit Problem in Australia

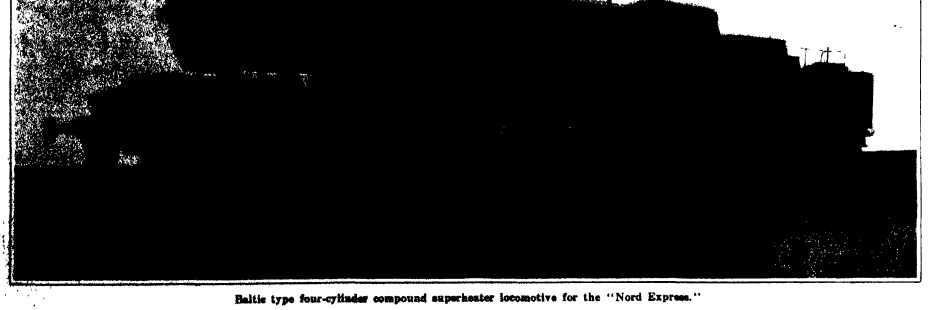
RABBITS are well known to be the curse of Australia, notwithstanding the fact that, according to the view of the commonwealth meteorologist, Mr H A Hunt, the burrows of these animals, by keeping the ground broken up make it more retentive of rainfall -a philosophical consideration that strongly suggests Mark Tapley Latterly, the Australians have been trying with considerable success to turn their curse into a blessing by marketing their surplus rabbits (dressed) in European countries

The Most Powerful European Express Engine

An Important French Locomotive Development

THE Chemin de Fer du Nord has recently introduced into service, huge "Baltic" type, four-cylinder compound superheater locomotives for operating the Nord Express, connecting Paris with Brussels, Berlin, the Baltic seaboard and St Peteraburg This international express service ranks as the fastest train service in the world, and, with 400 tons coach load, the French engine attains 75 miles per hour, developing in the cylinders about 2,000 horse-power.

Two engines of the "Baltic" wheel arrangement have been built by the Chemin de Fer du Nord for comparative working, the only difference being that the first engine, 3.1101, is fitted with ordinary locomotive firebox and boiler, while the later engine, 3.1102, has a marine pattern water-tube firebox. This firebox was designed by the Nord company's engineers, although actually constructed at the Creusot Works of the Schneider Company Both engines are fitted with apparatus for highly-superheated steam, and the cylinders in each engine are identical Instead of constructing the ordinary type boiler for saturated steam and placing a water-tube boiler for superheated steam over a simple engine, the same system of compounding is here employed in both engines



The previous largest engines in Europe are the "Pacific" type, class 10, of the Belgian State Railways, which have four cylinders, each 500 millimeters by 660 millimeters (19 68 x 25 98 inches) The new Nord engines have, however, two high-pressure cylinders, 440 millimeters (17.32 inches) by 640 millimeters (25 19 inches) and two low-pressure cylinders 620 millimeters (24 41 inches) by 730 millimeters (28 74 inches) Further, while the steam pressure in the Belgian engines is 200 pounds per square inch, the French engines carry a pressure of 227 5 pounds per square inch with direct admission from the boiler to all the cylinders whenever it is found desirable for starting

These French engines, although very much more powerful in starting effort than the Belgian locomotives, are of the same weight, loaded and empty, as the latter, but the boilers of the Nord engines have 23 per cent more heating surface

The chief interest in these new locomotives is the novel solution of the cylinder problem which has, for years past, been an obstacle in the design of very powerful locomotives, the difficulty occurring when specially large cylinders are necessary, either for low-pressure saturated steam, superheated steam, or extra low pressures in one-half of a compound engine The high-pressure cylinders are mounted outside the frames and drive on the center pair of the three sets of coupled wheels with cranks set at 90 degrees apart The low-pressure cylinders are inside the frames and drive on the forward pair of coupled cylinders The cranks in this case are also set at right angles to one another and each high-pressure is at 180 degrees from its corresponding low-pressure crank One of the low-pressure cylinders is set in advance of the other so as to get the centers of the piston rods close together Although intended for cylinders working at 80 pounds maximum pressure, this device is applicable to any system of engine with such modification as may be desirable The driving wheels have a diameter of 6 feet 8⅛ inches and the bogie wheels a diameter of 3 feet 4½ inches The firebox grate is 8 56 feet in length and 5 3 feet in width and the grate area is 46 square feet The total heating surface amounts to 4 294 93 square feet to which the water tubes and firebox contribute 1,097 95 square feet and the smoke tubes 2,629 6 square feet while the superheater surface is 667 38 square feet The boiler barrel has a diameter of 6 feet 2¾ inches The water capacity is 1,886 gallons, and the steam capacity 690 8 gallons The tractive force of these locomotives working compound, is 32,429 pounds, and simple 42 834 pounds

An interesting innovation is the adoption of mechanical stokers On the Northern Railway the express engines are served with "smalls" and tout-venant' which, to avoid choking the fire and evolving heavy smoke, must be laid on thinly and with great frequency Opening the fire-door frequently is injurious to the tube plate and tends to lower the temperature of the steam in the superheating pipes With mechanical stokers these and other objections disappear the fuel in fine powdery form may be blown into the fire box with suitable tuyères

In running order the engine weighs 102 tons, of which 24 tons is on the leading bogie, 54 tons on the coupled wheels and 24 tons on the trailing bogie The tender is of the standard Nord 8 wheels type and weighs 56½ tons, so that in working order these "Baltic" locomotives have a total weight on rails of 158½ tons

Baltic type four-cylinder compound superheater locomotive for the "Nord Express."

Some Locomotive Curiosities

Showing How Present Practice Was Reached by Trial and Error

By Herbert T. Walker

IT is only within recent years that the locomotive has been studied by scientific men on systematic principles, with the aid of elaborate testing plants and other special apparatus

The early designers of locomotives were not scientific men in the strict sense of the term They were mechanics who studied science in their leisure moments, and were not always well grounded in principles. They were, moreover, hampered with ideas of stationary engine practice, for the earliest locomotives were but little more than stationary engines on wheels Even the rails were laid on stone blocks after the manner of stationary engine foundations

Thus, the attempt to adapt a low speed stationary engine to a fast locomotive produced many curious and interesting examples

Drawings of many of these are in the writer's possession, and engravings of ten of them are here presented with a brief description

A fruitful source of trouble to the old locomotive designers was a tendency to follow the teachings of James Watt, who had laid down a fixed rule that the piston speed of a steam engine should not exceed 220 feet per minute The only way, then, to build a high-speed locomotive was to employ large driving wheels The culmination of this theory is found in engines built for the Great Western Railway (England) which originally had a track gage of 7 feet The engineer of this railroad was I K Brunel, who, although he was the greatest civil engineer who ever lived, fell into the same error as his contemporaries He wanted the fastest locomotives in the world, and when ordering them of various builders he limited the piston velocity with the result that when the railroad was opened for traffic (June 11th, 1838) the motive power superintendent, Daniel Gooch, was confronted by a collection of engines which made the roundhouse look more like a museum of curiosities than anything else

Two of the engines are illustrated herewith Fig 9 shows the "Ajax," the driving wheels of which were 10 feet in diameter Cylinders 14 inches diameter by 20 inches stroke Total heating surface, 474 square feet The wheels were built up of boiler plates A drawing of this engine was first published in the *Locomotive Magazine* (London) of 1901 by Mr G F Bird in his "History of the Great Western Railway Locomotives," and by the courtesy of the editors of that journal a reproduction is here given

The other 10-foot driver engine was a fearful and wonderful machine, for the engine and boiler were on separate frames, as shown in Fig 2 The object of this arrangement was to distribute the weight, as the rails of that period were very light The engine had a tender (not shown) behind the boiler where the fireman attended to his duties, but the engine driver was stationed on a platform forward of the driving axle, without any shelter from the weather The cylinders of this monstrosity were 16 inches diameter by 26 inches stroke Total heating surface, 623 42 square feet The weight of the engine carriage was 13 tons, of which only about 6 tons were available for adhesion, so that with the absurdly small cylinders the engine was almost useless for practical work, although it would go fast enough with a light train In fact it was reported that both this engine and the "Ajax" attained a speed of 100 miles an hour when running without a train, but this is very doubtful

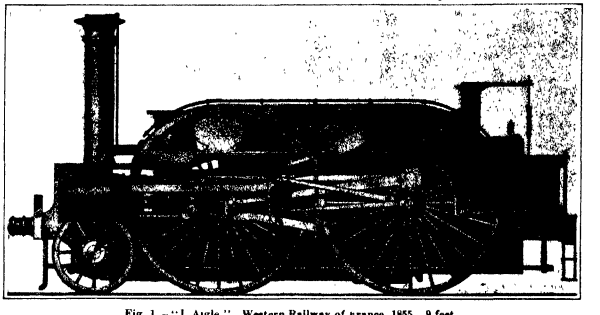


Fig. 1.—"L Aigle." Western Railway of France, 1855. 9 feet 4 inches coupled wheels. Boiler below the driving axles.

Other and more practical engines were built with large wheels as for example the "Cornwall," designed by Francis Trevithick in 1847 This engine is illustrated in Fig 4 It did good service on the London and North-Western Railway The boiler was slung below the driving axle, as a high boiler was considered unsafe for fast running The "Cornwall" was like a rare animal and attracted much attention, as it was considerably lower than the cars of its train The driving wheels were 8 feet 6 inches in diameter Cylinders 17½ inches diameter by 24 inches stroke Total heating surface, 1,046 square feet Weight, 30 tons A speed of 117 miles an hour was claimed for this engine but this is not credited by engineers Under official tests it attained a speed of 79 miles an hour with a light train Full particulars of this engine were published in the SCIENTIFIC AMERICAN of June 10th, 1905

The "Lightning," an American engine with large drivers, is shown in Fig. 3 This engine was of the "Crampton" type, the driving wheels being placed behind the fire-box. It was built at the Norris locomotive works in 1849 for the Utica and Schenectady Railroad The cylinders were 16 inches in diameter by 22 inches stroke. Driving wheel 7 feet in diameter As the heating surface of the boiler amounted to only 678 square feet, it was a poor steamer. Nevertheless it attained a speed of 72 miles an hour for a short distance with a light train. The engine weighed about 20 tons and was in service a little over one year

The last example of a large wheel engine is shown in Fig. 1. It had the largest coupled wheels ever used, namely, 9 feet 4 inches. It was designed by Blavier and Larpent for the Western Railway of France in 1855, and was exhibited at the Paris Exhibition of that year. The name of this engine was "l'Aigle." The cylinders were 16½ inches in diameter by 31½ inches stroke The boiler was below the driving axles as in the "Cornwall," but was so short of heating surface that the engine never did any useful work. To show that nothing is gained by excessively large wheels, we may point out that an engine with cylinders of the same diameter as that of "l'Aigle" and a stroke of 22 inches, with 6½ feet driving wheels would have given the same tractive effort with the same mean pressure of steam; and with this observation we may dismiss the subject of large driving wheels.

There was a still more interesting class of early engines which were called "compensated locomotives" They were the earliest balanced engines, and show some original attempts to overcome the erratic movements of a locomotive when traveling at speed without driving wheel counterweights The oldest of these engines is shown in Fig 10 It was built in 1833, and worked on a short road running between Bolton and Kenyon Junction, now forming part of the London and North-Western Railway No dimensions of the engine are available, but the driving wheels scale a diameter of 5 feet The equilibration of the reciprocating masses can be easily understood, for the oppositely moving parts connected to the vibrating arm or "side lever" partially balanced each other, although with the vertical boiler and high pitched cylinders the engine was probably an unsteady rider, if it ever went fast—which is doubtful.

The most important side lever locomotive ever built is illustrated in Fig 7. It was designed by the celebrated Crampton in 1847 and patented by him. The driving wheels were 6 feet in diameter Cylinders 16 inches in diameter by 20 inches stroke. Weight

Fig. 2.—The "Hurricane." Great Western Railway, 1838. 10-foot driving wheels. Boiler and engine on separate frames.

Total heating surface 1,371 square feet. This engine was named "Lablache," after a noted operatic singer of the day. Details of its performance cannot be given here, but we may note that the engine was officially timed at 79 miles an hour with a light train.

On one occasion the "Lablache" hauled a freight train of 430 long tons at an average speed of 30 miles an hour, which was no mean performance at that period. The peculiarity of this engine was that the cylinders inside the frames actuated vibrating arms connected to the outside levers called the "side levers." These side levers were coupled to the cranks in such a way that when the front driving wheel crank was, for example, on the back center, the rear crank was on the front center, and thus the stresses of these oppositely moving parts were balanced. Moreover, the cylinders, guides and vibrating beam fulcrums were all bolted rigidly to the frame and therefore not subject to the effects of crosshead vertical thrust, as in the ordinary locomotive. The "Lablache" was tried on the Midland and other railways in England, but no company would purchase it on account of its great weight, and it was in use only a short time.

Another curious locomotive was built in 1856 in which the "Lablache" arrangement of cranks was repeated, but the cylinders had double pistons and a separate rod for each crank. This design was patented in England by Charles Ritchie in 1848, but he did not build an engine until eight years later. This engine is shown in Fig. 5. As the two pistons in each cylinder always moved in opposite directions the fore and aft stresses set up by the reciprocating parts were neutralized, for the momentum of one piston and its connections was balanced by that of the other. This engine weighed about 25 tons. The wheels were 6 feet in diameter. Cylinders 12 inches diameter by 36 inches stroke, each piston having a stroke of 18 inches. Supposing the engine to be in the position shown in the drawing and steam admitted to the center of the cylinder, the pistons would be driven apart and the engine would travel forward. As coupling rods could not be used Ritchie designed a parallel motion, the two sets of which

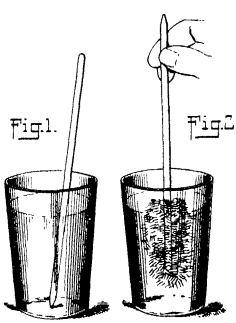
SOME LOCOMOTIVE CURIOSITIES

The Laboratory

Some Suggestions for Home Experiment



Experiments in Crystallization

By A. J. Jarman

DURING the process of crystallization of many chemical salts, some unusually peculiar phenomena occur It is well known that if a saturated or supersaturated solution of almost any salt is allowed to stand undisturbed for some time, many hours and sometimes days will elapse before crystallization will commence While if the vessel is disturbed, or the liquid stirred crystallization will start immediately and the heat that was absorbed in producing liquification, will be given out during crystallization A very good example of this was described in the issue of November 4th, under the heading "A Heat-Storing Water Bag" When hyposulphite of soda is dissolved in water at ordinary temperature a considerable quantity of heat is absorbed as the following experiment will show The temperature of the surrounding air was 70 deg Fahr Ten fluid ounces of water was taken and placed in a clean wide-mouth bottle, the temperature of the water being 60 deg Fahr Twelve ounces of *granulated* hyposulphite of soda was added to the water, and stirred with a glass rod until nearly dissolved. Upon inserting the thermometer the temperature fell from 60 to 30 deg Fahr and in the course of about one minute the temperature had fallen to 29 degrees

This experiment fully indicates the reason why in photography warm water must be used in the winter time in mixing the fixing solution, either for paper prints or plates, otherwise the time for fixing would be prolonged for a considerable period, and cause patchiness, in color, as well as an irregular fixed print.

Another interesting experiment is as follows Prepare a supersaturated solution of sulphate of soda

Crystallization started with unsterilized glass rod.

(this usually requires two ounces of the salt to one ounce of water) Heat two or three small glass tumblers and pour the supersaturated solution into each Cover the top of each vessel with a piece of sheet glass, and let the tumblers stand undisturbed until they have become quite cold It is well to prepare the vessels at night, allowing them to stand undisturbed until the morning They will then be ready for the next step in the experiment Take a glass rod, about 9 or 10 inches long and a quarter inch diameter Make one end red hot for about two inches, in either a spirit lamp flame or a Bunsen burner Suspend it to cool, and then stick a piece of gummed paper about five inches from the end that was heated, in order to identify it

As soon as the rod is quite cold, remove one of the glass plates from the vessel containing the cold solution of sulphate of soda, insert the end that has been heated, and stir the liquid No crystallization will take place

Turn the rod around, insert the end that has not been heated and stir the liquid Crystallization will begin at once, and will continue until the liquified salt has become a solid mass

The experiment can be repeated with the second or third vessel with the same result, providing the salt has not crystallized upon the end that was originally made red hot If crystallization has taken place, the end must be well washed by pouring warm water over it This peculiar property has been known in some instances to be retained by the glass rod for two weeks, when not touched, and kept from the atmosphere The experiment is not a costly one. Hyposulphite of soda can be purchased at almost any drug store for five cents a pound, and sulphate of soda at about the same price. The illustration in Fig. 1 shows the stirring without causing crystallizing; Fig. 2 shows the growth of crystals from the rod in the center of the saline solution.

Preparation of Small Quantities of Impure Radium Bromide

By James H. Doran

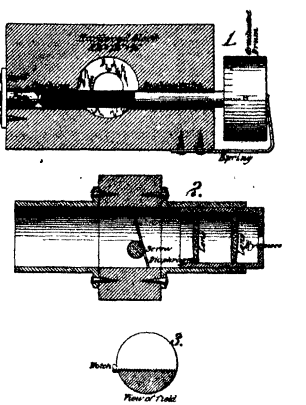
THE idea is undoubtedly held among most amateur chemists and physicists that experiments with radium are inaccessible to those who have only a limited fund for experimenting in this line However, those who have a fair chemical equipment can prepare samples of fairly active material with little trouble and with which a great many interesting experiments can be performed The radium in these samples is of course infinitesimal, but asserts its presence by ionising gases and discharging electroscopes, and by blackening photographic plates through paper and sheets of wood and thin metal

In the separation of active material from pitchblende, samples of the ore which are known to be high in uranium should be taken as these always yield the most active substances The ore is first reduced to a powder and roasted in a crucible for about 45 minutes and after cooling, pulverized to a fine powder It is then mixed with about twice its weight of sodium carbonate and a little sodium nitrate and the mixture is again heated for nearly an hour. It is then extracted with water, and filtered and washed until all soluble parts are washed away The insoluble portion is treated with a mixture of three parts C P sulphuric acid and one part C. P. nitric acid and this diluted with an equal amount of water. The acid should be added until effervescence ceases and until no more ore apparently goes into solution. The solution is then allowed to stand with occasional stirring for at least 24 hours The insoluble part is allowed to settle and the acid solution decanted If desired, this solution may be used for separation of the uranium contained in it After decanting, the residue is thoroughly washed and treated in the same manner with an equal mixture of C P hydrochloric acid and water This mixture which contains the polonium and actinium is then decanted and the residue washed and boiled with a saturated solution of sodium carbonate so as to change the still insoluble sulphates into carbonates The sodium carbonate solution is drawn off and the residue washed and digested with pure hydrochloric acid diluted with a little water This solution contains the active material which has now gone into solution It is filtered and a slight excess of ammonia is added to the filtrate Then it is again filtered and hydrogen sulphide gas is led into the clear solution until no more precipitation occurs After filtering, sodium carbonate is added to the filtrate and the precipitate thus formed is thoroughly washed Several grains of this mixture of active carbonates should be obtained from each ounce of ore

Enough dilute hydrobromic acid is added to dissolve the carbonates and the solution is filtered C. P. sulphuric acid is added until the precipitation is complete when the precipitate is washed by decanting until all of the calcium sulphate in the sample is dissolved or until only a few grains remain (the quantity of barium sulphate being often very small if only three or four ounces of ore are used) This residue is converted into carbonates by boiling with sodium carbonate solution and this again is converted into bromides by a slight excess of C. P hydrobromic acid. The solution is evaporated to dryness and is quickly transferred to glass stoppered bottles or is sealed into tubes. In this way a centigram or two of the radiferous calcium and barium bromides may be obtained from a pound of ore. However, if the quantity is very large and it is desired to obtain more active material this may be done by a series of crystallizations and recrystallizations until the desired activity is reached. The radium bromide is less soluble than the barium salt, hence it crystallizes more quickly.

The radiferous calcium and barium bromides obtained in this way are often self-luminous, the color of the phosphorescence varying with activity. The samples lose their phosphorescence if allowed to accumulate moisture but recover it again on being dried.

If the samples are very active they will produce fluorescence in barium platinum cyanide and [illegible] the scintillations of the a rays when held close [illegible] zinc sulphide screen and observed through a ma[illegible]fying glass. Good radiographs can be taken in a [illegible] hours' time with a few grains of the impure Ra[illegible] prepared in this manner, X-ray plates being the [illegible] to use for this purpose.



A Simple Micrometer

By Claude C. Kiplinger

THE instrument here described has been in use [illegible] some time on a home-made spectrometer and [illegible] given good satisfaction Although it is not intended to replace a first class filar micrometer, its simple construction renders it a desirable piece of apparatus

As in nearly all devices of this sort, the most important part is the screw. A metal rod, preferably of brass, 2½ inches long and three-sixteenths inch in diameter is threaded at one end for two inches of its length with either fifty or one hundred threads to the inch, according to the sensitiveness desired A metal drum, with its perimeter divided into twenty equal parts by a scale, is soldered to the unthreaded end of the rod, as shown in Fig. 1. This completes the moveable part of the apparatus.

A block of hard wood should be squared up to the dimensions shown in the sketch. A three-quarter-inch

A micrometer of simple type.

hole is bored through the flat side of the block, at its middle point, and a four-sixteenth-inch hole is drilled from end to end intersecting the former, as illustrated. The latter hole should be bushed at each end with brass tubes, in which the threaded rod turns easily, but without play A metal plate covers one end of the hole and a closely fitting steel pin is inserted, of such a length that the threaded rod having been introduced, the drum will be stopped about one-fourth of an inch from the end of the block. A spring presses on the drum and holds the screw firmly against the pin.

A sheet metal diaphragm with a three-eighths inch aperture is fitted in a slanting position, shown in Fig. 2, so that its upper part will fall into the same focal plane as the top of the screw. A notch is cut at one side of the aperture to serve as a reference point (see Fig. 3). Brass lens tubes are attached by means of flanges and wood screws. The inside of the tubes and the diaphragm should be blackened. A positive eye-piece of one-inch focus is used. However, a single convex lens of the same focus may be substituted.

After assembling the instrument, the eye-piece should be focused sharply on the top of the screw. The field will now appear traversed by a series of notches, as in Fig. 3. When the drum is turned through a complete rotation, each notch is made to shift its position by its own width. Hence, fractional parts of a notch will be indicated by the drum divisions. There is obviously no lost motion and if the threads are accurately and sharply cut very precise measurements may be made. This micrometer may also be used with a microscope.

Compensating Quadrant Crane

THERE is a certain type of machine now in common use that has been handed down to us, with little change, from the very earliest days of history. The crane as employed by the Egyptians in building the Pyramids was not radically different from the derrick of the present day. It consisted then, as it does now, essentially of an upright mast with a boom or gaff. Practically the only advances made in this type of machinery have been in the manipulation of the crane or the motive power utilized. Recently, a patent has been granted on a crane which is a decided innovation. The crane has no mast, but consists merely of a beam mounted on a frame in such a way that it can swing forward like the boom of a derrick while the load it carries moves on a virtually horizontal line as the beam is raised to the vertical position.

The beam is built up of rolled steel and is secured to a pair of quadrants of cast steel formed with teeth, to engage racks at the foot of the frame. The frame is mounted on a swivel base. The beam is raised or lowered by means of a horizontal screw which passes through a nut journaled to the quadrants. As the screw is operated, the quadrants roll on the toothed foot of the frame. Hence, the fulcrum, which is the point of contact of the quadrant with the frame, moves outward as the beam moves toward the horizontal and at the same time the length of the lever from load to fulcrum is reduced, owing to the bell-crank form of the beam and quadrants.

The compensating mechanism consists of a pair of arms hinged to the beam near the upper end, and secured to one end of a cable, which passes over a sheave at the top of the beam, and then runs to a point on the frame where it is permanently secured. As the beam is moved backward or forward, the arms are correspondingly swung on their hinges, so that their outer ends trace a practically horizontal line. At these outer ends the arms support the upper blocks of the hoisting tackle over which the hoisting cables run to a pair of winding drums. As a result of this "parallel motion" the load is not materially lifted as the crane is swung upward, and the bending moment on the beam is greatly reduced.

The accompanying illustrations show a model of a full-sized 4-ton crane, which has a lifting capacity of 2½ tons. In this crane the actual reduction in bending moment of the beam due to the compensating device is five-sixths; that is, a load of 120 foot-tons is reduced to 20 foot-tons, while the maximum thrust on the screw is less than 2¼ tons. The screw may thus be regarded as a simple controlling device rather than a means for shifting the load, the load being practically balanced. There is no bending moment on the screw, the thrust being exerted in line with its axis. In use the crane is provided with separate motors for actuating the screw and the winding drums, and the gear by which the crane is swiveled on its base. Thus the crane is self-contained, making it a very serviceable piece of machinery for docks, ships, wrecking cars, etc. It is the present practice in the construction of buildings to operate the cranes from a plant on the ground floor. Greater facility of operation would be afforded by the use of self-contained cranes, particularly in tall buildings.

Novel crane with traveling fulcrum and compensating device for moving the load on a horizontal line as the crane beam is raised.

Another Confederate Patent

IN the SCIENTIFIC AMERICAN of November 4th appeared a reproduction and account of a Confederate Patent No. 13. We have just examined a reproduction of another Confederate patent, which except as to names, number, title, date and signatures is like that already published, so its reproduction would not be interesting. This other patent is No. 149, issued February 18th, 1863, to D. W. Hughes of Arizona, and disclosed an improvement in breech plugs. An illustration accompanied the patent, in style and execution quite similar to the patent drawings of to-day. The patent describes a removable plug of a breach loading cannon, the plug having radially projecting lugs which turn into interlocking engagement with seats in the bore of the gun. The patentee, D. W. Hughes, is still living at the age of 83 at 437 North 3rd St., Hamilton, Ohio. Mr. Hughes' patent, like the earlier patent No. 13, above referred to, is signed by Rufus R. Rhodes as Commissioner of Patents. Mr. Rhodes was a former official of the United States Patent Office, having been appointed an assignment examiner on June 20th, 1857, and promoted to principal examiner in July, 1858. He resigned February 15th, 1861. The patent No. 13 was issued August 23rd, 1861, just a little more than six months after Mr. Rhodes left the United States Patent Office.

A New Patent Office Ruling on Perpetual Motion Machines

ALTHOUGH it might be supposed that the absurdity of perpetual motion had been completely exploded long ere this, every patent lawyer can cite numerous cases to show that even in this twentieth century of alleged scientific enlightenment many a deluded inventor is still trying to get a mechanical something out of nothing. To the credit of the patent profession at large be it said that the inventor is usually told that he is wasting his time and his money. It is frequently difficult, however, to convince an inventor that his schemes are impracticable, so that many an attorney, much against his will, is compelled to prepare specifications and claims which relate to an invention that is inoperative.

In the past it has been the practice of the Patent Office to demand a working model from the inventor of perpetual motion machines. The man who can not be convinced by an attorney that his machine is inoperative is not likely to be discouraged by any such requirement. The result is that many an inventor spends hundreds and perhaps thousands of hard-earned dollars in trying to build an operative perpetual motion model—a task which any one with an elementary knowledge of mechanics can tell him is hopeless.

To meet this peculiar situation the Patent Office has now made a ruling which must commend itself to every member of the patent bar, as well as to those engineers and inventors who come into frequent contact with the Patent Office Examiners. The Commissioner, in order to spare the inventor the necessity of parting with at least the government fees for an application, which must inevitably be rejected, has decided that hereafter no application for a patent on a perpetual motion machine will be considered at all unless a working model is filed in the very first place.

The exact wording of the Commissioner's ruling is as follows:

"The views of the Patent Office are in accord with those of the scientists who have investigated this subject and are to the effect that such devices are physical impossibilities. The position of the Office can be asserted only by the exhibition of a working model. Were the application to be forwarded to the Examiner for consideration, he would make no examination as to the merits, but his first action would be the requirement that a working model be filed.

"In view of all circumstances, the Commissioner has instructed that applications for patent on Perpetual Motion, complete in all other particulars, shall be held in the Application Rooms as incomplete until a working model has been filed. Such model must be filed within one year from the date of application, or the application will become abandoned. The Office hesitates to accept the filing fees from applicants who believe they have discovered Perpetual Motion, and deems it only fair to give such applicants a word of warning that the fees paid cannot be recovered after the case has been considered by the Examiner.

For these reasons it has been thought best to meet the inventor at the threshold of the Office and give him an opportunity to recover the moneys paid into the office, in the event of his failure to comply with the requirement.

Although misguided inventors may still persist in spending their money in attempts to furnish working models, there is much consolation to be found in a ruling which at least saves them the government fees on a hopeless application

Notes for Inventors

Tool for Attaching Wheel Tires A tool is shown in patent No 1,007,640 to James L Butler, Akron, Ohio, assignor to the American Tire & Rubber Co of Akron, for attaching a tire casing to a rim over compressible cores such as are now used in some tires The tool has a chain passed around the tire and rim and connected with a main lever so that the operation of the main lever may compress the casing and core, and the main lever is provided with a jaw to press the hooked edge of the casing into engagement with the rim flange and also means to guide it into such engagement

A Self-returning Exercising Dummy.—In patent No 1,007,028 to Wm P Armstrong, Washington, D C, assignor to The Strong Arm Mfg Co, is shown a dummy figure in the form of a man mounted so it can be rocked on a weighted base which has a rolling surface the bottom of which is flat so that the figure when knocked one way or the other will persistently tend to maintain or regain a fixed position A weight is connected by a suitable guided cord with the head of the dummy, thus aiding in the readjustment of the figure to its normal upright position

For Teaching Aviators.—Patent No 1,007,467 to Wm F Mangels of New York city is for an apparatus for teaching aviation and for testing aeroplanes and includes a car on a track and means for running the car at approximately the same speed as the aeroplane On the car is a frame and in the frame is suspended a power driven aeroplane and its operator, so the aeroplane can to a limited degree move laterally and lengthwise in the frame as well as up and down so the operator can drive the aeroplane at any speed and steer it in any direction, the car and its frame preventing dangerous accidents

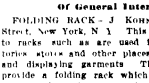
Drying Wood by Electricity—Alfred Upton Alcock of Perth, Western Australia, in a patent No 1,007,513 provides an electric apparatus for drying timber, which includes liquid electrodes adapted to engage the ends of the piece of timber to be dried, a source of electricity and conducting wires which lead from said source and have their free ends immersed in the liquid electrodes to form a circuit

A Novel Toy—Many of us can recall trotting, when small, on the foot of some older member of the family who crossing his knee would seat us on his foot and bounce us up and down A toy (patent No 1,008,547 granted to Claudius B Johnson of Fulton, Mo) simulates this action by means of two figures, one representing an elderly person sitting with crossed leg and the figure of a boy on the raised foot, the leg being pivoted and a counterbalancing weight being within the body of the larger figure, so that the figure of the boy can be trotted up and down for a considerable period

Demand Abroad for Smoke Consumers.—U S Consul Carl Bailey Hurst, Lyon, France, writes that owing to an increase in the smoke nuisance a municipal order has been issued at Lyon calling attention of manufacturers and others to an ordinance of a few years ago with relation to thick black smoke The consul adds "There seems to be an opportunity of introducing up this vicinity smoke-consuming systems or devices Any printed matter advertising such will be displayed in this consulate, and brought to the attention of those most likely to be interested"

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN



Electrical Devices.

WAVE DETECTOR—T H LYON, The Progess, 32 Morris Road, Southampton, England This invention relates more particularly to wave detectors of the kind known as rectifiers and which employ crystalline or crystalloid substances to be energised by electric oscillations and which may be employed in connection with wave meters as well as in the commercial and experimental sending of messages in wireless telephony and telegraphy.

Of General Interest.

FOLDING RACK—J KOHN, 117 W 10th Street, New York, N Y This invention refers to racks such as are used in garment factories stores and other places for supporting and displaying garments The object is to provide a folding rack which can be readily extended for safely supporting and displaying garments or other articles, or which can be folded when not in use to take up very little space

PROCESS OF REMOVING INK FROM PAPER—JOHN E RONSER, care of Morning News, Abilene, Texas This invention is illustrated in the accompanying engraving which is a diagrammatical view showing the apparatus that may be used in connection with

APPARATUS FOR REMOVING INK FROM PAPER.

the process The process removes printers' ink and analines from news, rag linen and bond papers, and pulps thereof The aim is to provide a process which will effectively remove the inks from papers so that the latter may be used again in the manufacture of other papers A further object is to provide a process which is comparatively simple and of great economy

LOCK BLOCK FOR PAPER ROLLS—J L OAR, 400 Victoria Avenue, Lynchburg Va In this case the invention is an improvement in plugs or brushes for use in paper rolls, being in the nature of a lock block which when inserted in the end of the paper roll will be locked therein from accidental displacement and will remain in position until the roll of paper has been used up

FRUIT PICKER'S LADDER—T O HERCHISSON, Waiterville, Ore The design is to furnish a ladder adapted for use in picking fruit and for use by painters and builders in any building operations and the invention provides a ladder including a movable platform easily adjustable to various heights for the purpose of picking fruit, erecting cornices, weatherboarding and painting houses, sand ing, sign writing and other work requiring the workmen to be elevated above the ground

COMBINATION COAT, HAT, PACKAGE, AND SATCHEL CABINET—W H JAY, Arcade Hotel, Le Roau, S D The aim in this improvement is to provide a cabinet having a locker and also having a satchel fastener arranged at the outside of the locker, and in which access to the locker, removal of the garment from the support, and the detachment of the fastener are controlled by a single lock on the door of the cabinet

COMBINED DRYING AND CONVEYING SYSTEM—A GRADY, 2703 South Seventh Street, St Louis, Mo This invention relates to a system for utilizing waste heat from a battery of boilers or the like in drying any material such as salt, saw-dust, or the like while conveying it from one point to another The system is readily accessible for the purpose of cleaning and manipulation

PACKAGE—W L BARTHERTON, care of W A Clark, Titanite Explosive Co, Corry, Pa This invention has in view a tubular container which is water proof and which can be inexpensively produced, the tube being constructed of paper or strawboard, or equivalent material, and given a coating of paraffin containing other ingredients of a water-proofing character

Heating and Lighting.

ACETYLENE GAS LIGHTER—H VAN HORNENBURG, Lake Placid Club Lake Placid, N Y The invention comprehends an electrically-operated gas lighter having two movable contact arms and mechanism connected with said arms for actuating the same, the parts being so arranged that the contact arms are brought into engagement with each other, a current is completed through them, and the arms are next separated in or near the path of the flame and are finally brought back to their respective normal positions, the arms thus making an idle contact, but without closing the electric circuit.

Machines and Mechanical Devices.

SAFETY DEVICE FOR ELEVATORS.—S. F. GLIMM, 3808 Avenue F, Brooklyn, New York, N. Y. This device is for use on passenger and other elevators. The invention refers more particularly to a device comprising in combination a lock for preventing the movement of the elevator car, means whereby the operator of the elevator can control the lock, and means controlled by the elevator door or other closure for controlling the first-mentioned means

REVERSING MECHANISM FOR POWER DRIVEN MACHINES.—C FREDERICKSON, Rice Lake, Wis. Among the principal objects which the present invention has in view are: the provision of a simple, efficient and durable means for varying the speed in transmission from a driving to a driven shaft; and to provide a mechanism of the character set forth, simple and effective in operation. The mechanism may be used in conjunction with any suitable machine

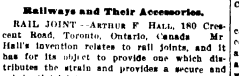
MOLD FORMING MACHINE.—C E SIMPSON, 640 Gallis Street, Portsmouth, Ohio. This continuously automatic acting machine employs an endless chain of carriers provided with pattern plates adapted to receive and deliver molding frames for the formation of drag and cope molds, it has a series of successively connecting pattern plates and an intermittent feed mechanism arranged to advance each of the plates to and from stations where the facing sand and ramming sand are delivered to the mold and to a station where the sands are rammed

FEED TABLE FOR TENTERING MACHINE.—B GARDNER, East Greenwich, R I The principal purpose of which the present invention has in view is to provide tension devices for feeding the cloth to the reciprocating bed of a tentering machine, and a take-up mechanism for lifting the slack of the cloth due to the return of the bed of the tentering machine constructed as mentioned

MECHANICAL EYES.—P C JACQUEROD, West New York, N J In the present patent the invention has reference to mechanical eyes for dolls, lay figures, or other use The object of the improvement is the provision of a practicable construction whereby the eyes may be capable both of the ordinary opening and closing movement, and of moving laterally.

Prime Movers and Their Accessories.

IGNITER FOR INTERNAL COMBUSTION ENGINES.—C MESSERSCHMID, 696 Bergen Street, Brooklyn New York, N Y This invention is an igniter or spark plug for gas and other internal combustion engines which is designed to operate on high and low tension circuits It is provided with a pair of jump spark electrodes and a pair of make-and-break spark electrodes operable exchangably, according to conditions The last named are preferably operated by an electromagnet incorporated with the plug structure The electrode carries the high tension electrode which extends therethrough and terminates in proximity to a fixed spark point to the inner end of the plug



BILGE PUMP.—G E BADGER, Mayger, Ore In this case the aim is to provide a rotary pump for handling which is driven by a friction wheel which may be thrown into and out of engagement with the flywheel of the engine by a system of levers and connecting rods which are operated by a treadle

ROTARY MOTOR.—J MACKEY, Steamboat Springs, Colo In the motor forming the subject of the patent obtained by this inventor there is a rotor having peripheral blades and mounted on a hollow shaft having a slide valve, controlling openings in the hollow shaft and in the hub of the rotor An auxiliary casing is mounted on the shaft at one side of the rotor through which the motive fluid passes to the exhaust

SPARK PLUG.—W S WITTER, Toledo, Iowa, In this invention the improved plug consists of a case cylindrical in form and provided with means for engaging an engine cylinder and having a plunger acted upon by the compression and moved in one direction thereby, and in the opposite direction by a solenoid coil of which the plunger forms the case.

Railways and Their Accessories.

RAIL JOINT—ARTHUR F HALL, 180 Crescent Road, Toronto, Ontario, Canada Mr Hall's invention relates to rail joints, and it has for its object to provide one which distributes the strain and provides a secure and substantial joint, presenting a smooth and continuous surface to the wheels. Another object is to provide a rail joint which will protect the ends of the rails The accompanying illustration presents a side elevation of the invention The neighboring ends of two rails are indicated by the dotted lines midway the saddle members used with the joint and shown in position. The saddle in connection with the heads of the rail presents a smooth and continuous surface to the wheels, and the wheels pass over the saddle the strain the pieces is distributed through the length the saddle, thus greatly reducing the possibility of fracture of the parts.

RAIL JOINT.

GRAIN CAR DOOR.—J. C. DOBIE, Onawa, Iowa, and J. L. ROBB, Anistead, N. Mex., assignors of E. M. Hoover, 808 N. Adams Street, Carroll, Iowa. Among the various provisions of the invention are: To provide in a car a door which preserve the thickness of the wall of the car when the door is open; to provide a door and frame to prevent warping or disarrangement of the door to permit leakage to pass the same; to provide a holding frame for a door to maintain the latter in locked position; to provide a plate-metal sill to support the door and form a guiding track therefor; to provide a door to prevent obstructive lodgment of articles behind the door when the same is closed; and to provide a chute in said door for the handling of grain or flowing freight.

RAILWAY RAIL AND TIE FASTENER.—J. S. SHORT, 1015 E 11th Street, Chattanooga, Tenn. This invention is especially adapted for use with reinforced concrete ties The object is to provide a device which will easily and securely hold the rail in position on the tie. Another object is to provide a means which is cheaply produced and which will consist of few parts, thereby lessening the cost of such devices in railroad constructions.

SPIKE HOLDER—J M POWELL, Los Gatos, Cal The object here is to provide a holder, having parts thereon for engagement with a tie plate on rail chair and another portion for engagement with the web of the rail, the holder when in normal position being in contact with the head of a spike, whereby the spike is held against loosening and the danger of spreading rails is obviated.

RAILROAD TIE—J F O'NEILL, 159 East Front Street, Trenton, N J An object of the inventor is to provide a tie, preferably made of concrete, which tie is composed of a series of parts flexibly fastened together, two of said parts carrying the pair of rails, and so disposed that these parts will give slightly as the wheels of the train pass over the rails.

Pertaining to Recreation.

SWING—G. D. TUCKER, Meridian, Miss. The oscilating motion of this swing traverses the support for the swing over the ground An object of this invention is to provide a support rotatably supported on suitable rollers, with means for driving one or more of said rollers by the swinging motion of the swing, so that the device as a whole will move over the ground, and if desired about a common pivotal point Another object is to provide means so that the swing may be moved while the device as a whole remains stationary on the ground

Pertaining to Vehicles.

COMBINED SECTIONAL TIRE AND WHEEL RIM.—FRANK M. HURST, 222 McDougal Street, Brooklyn, New York, N Y Some advantages over other tires, in this invention, are 1 In case of puncture it is not necessary to stop and repair, as puncture of one ball will not injure any other part of tire and one can continue to one's destination or can repair at once in a short time 2. A tire blow-out while going at high speed has caused the loss of many lives and the wrecking of machines This will not be the case if one of these balls blows out, as the rest of the tire will not collapse 3 Requires no pumping up 4 There is no necessity of having tire chain to prevent slipping 5 Skidding has been brought to a minimum. 6. Any injured part

COMBINED SECTIONAL TIRE AND WHEEL RIM.

can be replaced without tools 7. The small cost of a section of this tire in comparison to a new one of any kind. 8 If the saving of a life is the only thing to be considered, it would alone be worth many times the cost of any other tire Life is worth the price of a sectional safety tire No one knows when one will be running at high speed and a tire "blow-out" which will wreck the machine and perhaps cost owner and friends their lives or broken limbs 9. The inventor will sell one-half interest in this patent to further its progress and will take out patents in four European countries. A side view of a wheel with sections of the tire in position is shown herewith.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

AUTOMOBILES.

A NEW WHITE STEAMER. Model C-O, complete with top. Will put on a very reasonable price. Address A. A. Hopkins, 261 St. Nicholas Ave. New York City.

BUSINESS OPPORTUNITIES

A STRONG, old established, manufacturing company, with a national selling organization, wants to add a new line of building material or equipment to manufacture and sell. Address X, Box 773, New York

FREE SAMPLE goes with the first letter. Something new. Every firm wants it. Orders from $1.50 to $50.00. Nice pleasant business. Big demand everywhere. Write for free sample. Metallic Mfg. Co., 68 E. Lake, Chicago.

OPEN FOR OFFERS. States and Canadian Patent Rights for Household Essentials and one Military approved article of commendable Selling value, full outright or shares and cash to substantial company. Dale Marshall, Consulting Engineer, Cambridge, Scotland.

WILL BUY NEW PATENTED EGG CASES, egg boxes, shipping cases, incubators or brooders, operating machines, in fact anything for the poultry trade, especially if of wood. Must be better than anything of the kind on the market and priced right. Owner has an opportunity to turn your ideas into money. Send sketch of article and state your price in first letter. Address Buyer, Box 773, New York, N. Y.

A HIGH CLASS INVESTMENT.—Salesman wanted in every City and Town East of the Mississippi River. Exclusive territory. Contract will be entered into with one who can show credentials as to character, ability, record, etc. Investment, insurance and Real Estate man preferred. A big opportunity for hustling business-getters to represent a large Eastern Corporation offering the public a safe, profitable and attractive investment, backed by the endorsements of men of National reputation and standing. Address Manager, 607 Metropolitan Bank Building, Washington, D. C.

DEAFNESS.

THE DEAF HEAR INSTANTLY with the Acoustican. For personal use, also for churches and theatres. Special instruments. You must hear before you purchase. Booklet free. General Acoustic Co., 26 Beaver St., Jamaica, N. Y. City. Paris branch 6 Rue d'Anouve.

PATENTS FOR SALE

FOR SALE. Recently patented Railway-Track Connection Patent. No Royalties. Reasonable offer considered. For further particulars, address Bertalan Takacs, Box 181, Morris, N. J.

POSITION WANTED.

ENERGETIC YOUNG MAN, trained in science and engineering desires a position where industry and ability will bring advancement. Is now employed as engineering superintendent of large manufacturing plant, at present a foreman in the engineering department of a large corporation. Position, Box 774, New York.

PROPOSALS.

PROPOSALS FOR BRICK DORMITORY, CENTRAL STEAM HEATING AND ELECTRIC PLANT. Department of the Interior, Office of Indian Affairs, Washington, D. C., November 15, 1911. Sealed proposals, plainly marked on the outside of the sealed envelope: "Proposals for Brick Dormitory, Central Steam Heating and Power Plant, for the Rapid City Indian School, South Dakota," and addressed to the Commissioner of Indian Affairs, Washington, D. C. will be received at the Indian Office until 1 o'clock, p. m., December 26, 1911, for furnishing materials and labor for the erection of a brick dormitory, central steam heating and power plant, at the Rapid City Indian school, South Dakota, in strict accordance with the plans, specifications and instructions to bidders, which may be examined at this Office, the offices of the Superintendent of Construction, Denver, Colorado, the American Contractor, Chicago, Ill., Scientific American, New York City, the Improvement Bulletin, Minneapolis, Minn., the Journal, Rapid City, South Dakota, the Bee, Omaha, Neb., the United States Indian Warehouses at Chicago, Ill., St. Louis, Mo., and Omaha, Neb., the Baltimore and Ohio Railroad Depot at St. Paul, Minn., and at the school. For further information apply to the superintendent of the Rapid City Indian School, Rapid City, South Dakota. C. F. Hauke, Acting Commissioner.

REAL ESTATE.

TEXAS INVESTMENTS.—Buy farm orchard garden lands near Houston, the greatest and most prosperous city in the southwest, where values are rapidly rising. Quick and fortunes made in real estate in short while. Many farms if desired. Single crop pays for land several times annually. Address R. C. Robertson, 84 Elkin Bldg., Houston, Tex.

WANTED.

WANTED.—One chemist at $6.00 per diem; two physics laboratories at $4.00 per diem; one second-class laboratorians at $3.00 per diem; and two fourth-class laboratorians at $2.00 per diem. The above examination will be held January 4, 1912, at the Navy Yard, Washington, D. C., for filling the above positions at the Naval Proving Ground Indian Head, Md. For further information, address, "Commandant, Navy Yard, Washington, D. C."

WANTED.—A man or woman to act as our information reporter. All or spare time. No canvassing. Salary $21 to $50 per month. Nothing to sell. Send stamp for particulars. Inter Association, 301 Association Bldg., Indianapolis, Indiana.

MISCELLANEOUS.

HEALTH CULTURE.—Be forty months "Old Tyler" at a year. Be a younger. HEALTH CULTURE, by Dr. Jeanne Bids. New York. How to Get and Keep Health Without Drugs.

IF YOU HAVE EVER LOST MONEY in mining stock, patented, have some good to dispose. Patented and Unpatented Lands, Central Savings Bank Building, Denver, Colorado.

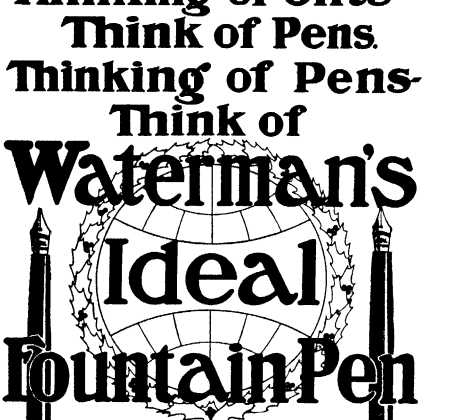
WANTED FOR ENGLAND. If you have a commercial proposition for export, write us. We are Export Commission Merchants and Manufacturers' Agents. Established 1897. Highest references. Box 773, N. Y. City.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12576) L. W. asks: Will you please give me a clear definition of "power factor" and "KVA," expressions used in electrotechnics, and illustrate same by example? A. "The 'power factor' of an alternating current circuit, or apparatus, is the ratio of the electric power in watts to the apparent power in volt-amperes." This is the definition as given in the Standardization Rules of the American Institute of Electrical Engineers. It is official. The true power of an alternating current divided by the apparent power, which is the volt-amperes entering the apparatus, gives the power factor. The volt-amperes apparently entering the apparatus multiplied by the power factor give the true power of the apparatus. The apparent power is the KVA, the kilo volt-amperes. You will find this fully explained in Sloane's "Handy Book," which we can furnish you for $3.50.

(12577) W. D. C. asks: Why does the honeysuckle vine grow to the left just contrary to the growth of all other trailing vegetation? All vines seek the sun or grow to the right, except the honeysuckle. Why is this? A. Many plants twine in the spiral or a right handed screw, or "against the sun," or "from left to right." The common garden bean and the wisteria have this habit. Other plants like the hop and honeysuckle twine in the opposite direction, presenting a spiral of a left handed screw. A most interesting account of these phenomena will be found in Darwin's "Movements and Habits of Climbing Plants."



(12578) F. L. Y. asks: How high does a person have to go before the earth becomes invisible to the sight? Any object is just visible which *like* one minute of arc. The earth will subtend an angle of one minute at a distance of a little more than 27,000,000 miles, and hence would be visible as a point at that distance, but would not show any disk.

(12579) D. E. says: I notice in a recent number of your paper an item in which you say that some process of restoring the appearance of a felt hat, that had become some what rusty, would fill a long "felt" want. I have solved this problem by wiping my hat with the same cloth I polish my shoes with. The blacking I use does not "crack" when applied to the hat and an occasional application keeps it looking nice.

(12580) R. F. McK. says: Please give me a solution of the following. If a tube 3 feet high and 6 inches in diameter is filled with water, and has a piston fitting the tube 1 inch in diameter, will the force required to push the plunger up in the tube 1 inch equal the force required to lift a column of water 1 inch in diameter and 3 feet high to the height of 1 inch? A. The pressure of water in the tube is equal in all direction at any given point. At the moment your plunger starts to rise, it is resisted by a head of 3 feet of water, that is, by the weight of a column of water 3 feet high and the area of the plunger. But as the plunger rises, the height of the column decreases. If you had a tube around the plunger, raising the plunger 1 inch would raise the entire body of the water in the tube 1 inch, and the plunger would operate under a constant pressure equal to 3 feet head of water, but in the illustration you give the rise of the plunger of 1 inch will cause a very much smaller rise of the surface of the water, so that when the plunger has completed its lift of 1 inch it will have little more than 35 inches of head of water above it, and the average pressure will therefore be about 35¼ inches of water. Obviously, if your plunger traveled the whole 3 feet and came to the surface of the water at the completion of the 3 foot travel, there would be no pressure against the plunger due to water head, since the plunger would emerge from the surface of the water. Similarly, the pressure on the plunger decreases with every inch of its travel upward.

(12581) J. C. J. asks: If a substance could be found which is heavier than water and *less compressible*, would it sink in any depth of water? A. If a substance could be found which is slightly heavier but less compressible than water, it might sink in water till it had reached the place where it was of the same density as the water at that place and there remain. The water at the bottom of the ocean *is* about 1/20 denser than at the surface; hence this supposed material could not be as much as 1/30 heavier than water at the surface of the ocean. No such material is known to exist.

Thinking of Gifts—Think of Pens. Thinking of Pens—Think of Waterman's Ideal Fountain Pen

THERE is nothing that can show more consideration for beauty, service and quality. A useful present that is easy to buy and send. Made in sizes and styles to suit every hand and writing requirement. There are plain pens and diamond-mounted pens and all intermediates, to suit your purse and the occasion. There is the same superiority in all. Fountain Pens, to be satisfactory and permanent, must have the patented parts found only in those bearing the trade-mark **Waterman's Ideal.** Fine, medium, coarse, stub and oblique points.

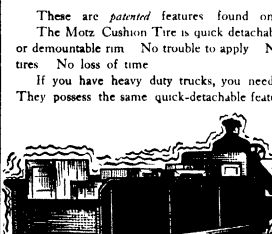
How to Double the Life of Your Light Delivery Car

Take *off* solid tires—*put on* Motz *Cushion* Tires. Thus save your *car* from a thousand bumps and jolts each day and save *yourself* 75% in upkeep cost. Your car thus equipped will give you *two* years' service where it would have given you but *one* before.

For the Motz *Cushion* Tire is *lively*. It has the *resiliency* of a properly inflated pneumatic, and the durability of the average *solid* tire. These combined features make it the *only* tire for light delivery cars.



THE MOTZ CUSHION TIRE

Observe in the illustration above, the three special features in Motz Cushion Tires which give them pneumatic resiliency and also do away with skidding.

DOUBLE TREADS
—UNDERCUT SIDES
—SLANT-WISE BRIDGES

These are *patented* features found only on Motz Cushion Tires. The Motz Cushion Tire is quick detachable. Fits any universal clincher or demountable rim. No trouble to apply. No removing wheels in replacing tires. No loss of time.

If you have heavy duty trucks, you need Motz *Demountable Solid* tires. They possess the same quick-detachable feature as the Motz *Cushion* Tire.

Let us send you more facts and figures showing the economy of Motz Cushion and Solid Tires. They mean a big saving to any one who operates *commercial* cars. In writing, please ask for Booklet 93.

The American Merchant Marine

To the Editor of SCIENTIFIC AMERICAN:

A correspondent in a recent issue of the SCIENTIFIC AMERICAN set forth the difference in the cost of operation of steamers operated under the United States navigation laws and those which operate under the navigation laws of foreign countries. The higher wages and feeding stipulations are given as the reason that the cost under our laws would amount to something like $6,000 on the average sized tramp plying in foreign trade against the American owner, even though the laws allowed him the privilege of buying foreign tonnage and securing American registration. This is true. But why should our navigation laws compel an American citizen to employ American crews in foreign trade? Even under the present subsidy laws under which a few American lines operate, the number of Americans employed is limited. Why should not an American shipowner have the same right to employ whom he pleases as has an American railroad builder or any other employer of labor?

This year we have the greatest movement in export cotton that the United States has ever seen. All moving in foreign tonnage. Our Gulf and West Indian trade is constantly increasing and it is practically carried on with foreign built and owned tonnage. The earnings of foreign tonnage this year due to the immense export movement from the United States as well as from goods imported will be tremendous and the various owners and investors abroad will receive heavy dividends. As the United States are not investors in foreign shipping, nothing will come to this country for distribution in the way of dividends. In this great fleet that operates under the flags of foreign nations, is no American sailor. Under present conditions we pay the freight, but we distribute nothing in the way of dividends to Americans.

Our navigation laws say that we must employ so many sailors on American ships—so many according to tonnage of the ship. Yet the navigation laws have killed American shipping in foreign trade. Hence there are no American sailors in foreign trade. Of what benefit are the navigation laws?

There is another statement that your correspondent made, and like many similar statements of a erroneous nature, retards the solution of the restroation of the American flag to the deep sea trade. The particular statement that I now refer to is that the "German government guarantees a dividend to the North German Lloyd of 7 per cent on its stock." Of course this is taken as subsidy payment and if it were true it would be a subsidy, but it is not, but it is astonishing that such statements continue to be made when the truth can readily be ascertained. Now the facts are that the North German Lloyd paid 3 per cent dividend last year and 1½ per cent the year before and before that nothing. The North German Lloyd is pre-eminently a passenger line and in the panic of 1907 cut into its earnings heavily. Fast passenger steamers have their advantages for the United States trade as well as they have for foreign, and fast steamers under the American flag are desirable.

It might be well held, that for certain routes, under the American flag, mail subvention is necessary to enable the American line to establish itself. But this policy has been so far ineffective because of the extraordinarily higher cost of building in the States as compared with the cost of the foreign builders, and this condition will have to be adjusted ere the mail subvention act will have any beneficial influence on the shipping industry of the United States. The one thing that will stimulate American interest and investment in shipping is to give Americans the right to engage *tot* the world's commerce on the same terms that favor foreigners. Give the right to an American to buy a foreign steamer and grant it American registration. Give him the freedom as to crews that foreign steamship owners enjoy. Compel him to have American officers. Steamers so registered to engage in foreign trade only.

To-day we have practically no American steamers engaged in foreign trade and no American sailors, so the continued opposition to a free ship policy is difficult to understand. We can hurt no American interest in foreign shipping as there is no American interest to be hurt. If it hurts any interest it will be that of foreign steamship interests.

Why is the present policy continued? Possibly in the hope that the Americans will be willing to allow a wide-open subsidy bill to finally become a law, and possibly to the fact that shipping generally is but little understood by the American people. But the interest is growing and growing rapidly and the interest taken in the Panama canal is stimulating investigation. Ere the Panama canal is opened it will be recognized that the restoration of an American merchant fleet to the deep sea foreign trade is but second in importance to the tariff as an issue in which the country is vitally concerned.

Some time ago President Bowles of the Fore River Shipbuilding Company stated that it would take ten years to build a fleet that would carry the sea commerce of the year 1910. Yet all the time our over-sea commerce is increasing yearly. It has recently been given out, that our domestic shipyards with government work and the orders for steamers to be ready for operation on the opening of the Panama canal, have all the work they can handle. What then shall the American people do? Rest quiet and allow foreign shipping nations to reap the benefit of our investment of $400,000,000 in the Panama canal? Is that what the United States built the canal for?

Let the American people answer.

Chicago, Ill. CHARLES DEPREZEE.

The Technique of Clam Digging

To the Editor of SCIENTIFIC AMERICAN:

"It pays to advertise" is something we often hear, and it certainly does, but the statement you made in a recent ad. in the *Literary Digest* regarding the technique of clam digging does not add any luster to an advertisement, as it is so very evident that the party who wrote the ad was a long way off from his subject.

Now, this is not in the sense of a knock, for only people who live along the coast are supposed to know anything about digging clams in the commonly expressed sense of the words. Everybody who lives in the Puget Sound region has an opportunity to know that you do not dig clams out of a boat with a rake, and I presume that our eastern clams have the same habit of keeping far below the rake's reach.

I like the SCIENTIFIC AMERICAN so well that I dislike to see any misstatement of this sort, therefore I am telling you that the way we dig clams in this country is to take a good stout spade or fork, and go down to the beach when the tide is out, and get busy just the same as you would to dig potatoes. Still, perhaps I should explain to the man who wrote the ad that you do not dig potatoes with a hayrake. In any event, I hope the information will be of some use, as it is given in all good friendship.

Seattle, Wash. HUGH N. JOHNSON.

The Current Supplement

IN the present issue of our SUPPLEMENT, No. 1876, Prof. Woodworth discusses the Psychology of Light or, in other words, the subjective aspect of the science of optics. Mr. Coleman contributes an article on modern methods of bunkering steamers. A very interesting topic treated in this number is that of fireless locomotives. Malaria is one of the most widespread diseases, and its study has of late been receiving a great deal of attention, with results which are most gratifying. Some facts about malaria, derived from Dr. Howard's govern-

ment publication, and a summary prepared by Sir Roland Ross, are presented in this issue. Many have marveled at the extraordinary power which carrier pigeons possess of finding their way back to their home. A scientific discussion of the *modus operandi* of this remarkable performance is discussed in an article by M. Tovia.—Insect aviation presents certain features which are not as yet incorporated in artificial aviation as practiced by man. The subject is lucidly expounded in an illustrated article derived from *La Nature*.—The Sixty-Inch Reflector of the Mt. Wilson Observatory is briefly described.—An article reproduced from *Engineering* tells how the government aids the man out-of-work in France.—A. P. Thurston discusses from a scientific standpoint the stability of aeroplanes.—We have become accustomed to the term "plant psychology." The senses of plants forms the subject of a brief article derived from *La Revue*.—Major Squier, the originator of the system, describes the use of wire directed electric waves in multiplex telephony and telegraphy.

The Strength of an Aeroplane

(*Concluded from page 558*)

other is to allow streams of smoke to flow past the model. Both methods show the direction of flow at all parts of the current except where the eddies are so violent as to make the thread flutter and the smoke streams break and lose their identity. The thread is more convenient to use than the smoke, but if too long will not accurately coincide with the stream-line, owing to the effect of tension. The smoke coincides with the direction of flow at all points, and, as Prof Marey has shown, may even indicate the velocity at all parts of the current, if the smoke-streams be emitted from nozzles vibrating at a known rate transversely to the current. In this case the smoke streams are wavy, and show by the number of waves per inch what is the speed of the current at the place of observation. The number of waves per inch can easily be counted on a photograph of the model and of the smoke-streams surrounding it. Indeed, the velocity and direction of flow for an entire longitudinal section of the current about the model may be realized by a glance at the photograph if the smoke streams surrounding it. Indeed, the comb placed transversely to the current and vibrated lengthwise, say ten times per second, as done by Marey.

Mr. Curtiss is at present trying different methods of producing distinct and clearly visible lines of smoke. At first air was sucked over the surface of ammonia in a bottle, thence over hydrochloric acid in a second bottle, thence through holes in a tube placed across the wind current. But the smoke so produced is pale and requires good lighting in a dark wind-tube to render it distinct enough for easy observation and photography. It is hoped that a simple method may be found whereby dense black smoke streams may easily be produced and led into the current.

The absolute velocity of the air in the Curtiss wind-tube was found by a screw anemometer to be about 25 miles per hour at the middle of the current. The relative velocity at different parts of a section of the current was found by observing the deflection produced on a straight exploring wire, like a knitting needle, ten inches long, suspended from a horizontal wire fixed transversely to the stream. When the point of suspension of the exploring wire was moved across the tube, the suspended wire was deflected from the vertical less and less as it advanced from the mid section toward the lateral wall. The impact pressure of the air against the wire is proportional to its displacement along any longitudinal line of the current. Hence, of course, the velocity is as the square root of such displacement. In this manner the speed of the current was observed to decline about two per cent from midstream to within two inches of the lateral wall, as previously stated.

The wind-tube and tension tongs described in this article were designed by Mr. Curtiss and Dr. Eahm, who were experimenting together. Two other contrivances were devised for finding the tension in aeroplane wires; one being an instrument for giving the pitch of the wire in vibration, the other being an in-

Bring Us Your Waterproofing and Finishing Problems

With our complete line of Waterproofing Compounds, Dampproof Coatings, Scientific and Technical Paints and Enamels, we are in the best position to solve your problems

Walls and Ceilings Finished with ASEPTICOTE
Woodwork and Mantel Finished with SNO-WITE

TRUS-CON
ASEPTICOTE

A flat, washable, durable, sanitary, decorative finish for interior walls. Perfectly aseptic and sanitary. Easily cleansed with soap and water. Most artistic in appearance. Manufactured in great variety of tints. Applied on interior surfaces of plaster, cement, brick, wood, burlap and metal.

TRUS-CON SNO-WITE

An enamel of the very highest quality for finishing interior surfaces of wood, metal, plaster and masonry. Produces a finish with a delicacy of tone, softness, whiteness and luster that cannot be excelled.

Walls Ceilings and Columns Finished with

TRUS-CON INDUSTRIAL ENAMEL

A gloss coating of whitest white, with powerful light-reflecting qualities, for treating factories, work rooms, enclosed light shafts, etc.

TRUS-CON FLOOR ENAMEL

Produces a tough, elastic and reasonably durable finish on all cement floors, rendering them washable, stainproof, oilproof and dustless.

Trus-Con Waterproofing Paste, integral waterproofing for concrete.
Trus-Con Stonetex, a liquid cement coating for stucco concrete and brick.
Trus-Con Plaster Bond, a stamp retarding paint for interior of exposed walls.
Trus-Con Por-Seal, a transparent coating for dampproofing exposed masonry.
Trus-Con Edelweiss, a durable artistic enamel for exterior surfaces.
Trus-Con Dairy Enamel, durable sanitary enamel for dairies and creameries.
Trus-Con Laboratory Enamel, for resist chemical fumes in laboratories.
Trus-con Bar-Ox, most advanced protective coating for iron and steel.

strument for showing the lateral displacement of the wire by a given force, from which the tension could be read in a reference table or along a specially designed index scale.

Some Locomotive Curiosities

(Concluded from page 555.)

were connected by crossed rods as will be understood by examining the illustration. This engine never did practical work. It was jacked up clear of the ground and tried under steam in January, 1856, at Kew, near London, where it was sharply criticized by some engineers. The writer saw it in the early sixties when it was fast rusting away in the stable yard of an inn near Kew Bridge.

Double piston balanced locomotives were patented by Bodmer in 1834, and some engines were built for English railways in 1842. The rod of one piston worked within the hollow rod of the other and they were connected to oppositely disposed cranks, which were four in number. As the mechanism was internal and the appearance of the engines differed in no wise from the ordinary locomotives of the day, they are not illustrated here.

The next remarkable locomotive selected is illustrated in Fig. 6. This engine was a partial repetition of the "Hurricane" (Fig. 2) for the boiler and running gear were on separate frames. It was designed for the Philadelphia and Reading railroad by G. W. Nicholls and was put to work in 1847. This engine was appropriately named "Novelty." The cylinders were 18 inches in diameter by 20 inches stroke. Driving wheels 3 feet 10 inches in diameter. The weight of the engine proper was 21 tons, and the frame carried a cylindrical iron water tank which had the appearance of a boiler. This was used as a condenser and feed water heater, while the boiler was carried on a separate frame behind the engine. This, in turn was coupled to a tender which does not appear in the illustration. The boiler had return flues and burned anthracite coal. It had a total heating surface of 1,085 square feet. The fire was urged by a fan placed in the cab. The condenser tank was surmounted by a large smoke stack, but as nothing passed through the latter save the surplus exhaust steam from the condenser it was apparently placed there merely for appearance. Steam was carried from the boiler to the engine by a jointed pipe. This engine hauled coal trains of 750 tons at 10 miles an hour. This complicated piece of machinery only worked for a short time.

Complicated machinery is not, in itself, objectionable, and when complication enables a necessary function to be better performed it is allowable, but one can scarcely see how such a machine as is illustrated in Fig. 8 could have been seriously considered in the light of modern practice. Nevertheless, this engine was built in 1881, and ran on the Canada Southern Railway. It was designed by Eugene Fontaine. The cylinders were 16 inches diameter by 24 inches stroke. The engine weighed about 40 tons. The driving wheels were 6 feet in diameter, having frictional contact with wheels 4 feet 8 inches in diameter, which were integral with wheels 5 feet 10 inches in diameter running on the rails. In other words instead of propulsion by power applied directly to the rails as in the common locomotive, two extra wheels were interposed to effect the same result. The "Fontaine" was a fast engine, for it drew two coaches 111 miles in 98 minutes, but many ordinary locomotives traveled faster with heavier loads. Geared engines were tried as far back as 1838, but it was then found that a gain in speed meant a loss of power, and as locomotives are required to haul loads, those engines were short lived. The "Fontaine" engine was not original, as the same arrangement was patented in England by Johnson in 1848.

The foregoing notes will, perhaps, give a good illustration of the adage that "History shows us what to avoid."

Caryl Davis Haskins

CARYL DAVIS HASKINS one of the best known electrical men of this country, died Saturday morning, November 18th, in Salt Lake City. Mr. Haskins

The Technique of Clam Digging

It has a technique and it is not easily learned. There is a certain way of handling the boat, of pushing the rake with its absurdly long handle into the water, of scraping the clams into it, of raising the rake—why there is as much technique about it as there is in playing a piano. You may debate with a disputatious person if it is more useful.

Probably there isn't any book on the technique of clam digging and there isn't a periodical devoted to it exclusively.

If there was a new development in the technique of clam digging, the **Scientific American** would record it, as it did the development of the steam oyster dredge and ever so many other things, including those departments of science which have their own technical publications for specialists in them.

The **Scientific American** covers the whole field, but it confines itself to the important things, those which affect the life of a whole people, rather than those which affect only a few individuals.

What it really does is to give the news of civilization. It has been doing that for sixty-seven years. It is doing it now better than ever it did, on a bigger, broader scale. It is growing and widening as science is developing, and always it maintains its authority.

See Correspondence Column, Page 564.

The test of a magazine's merit

is that its readers tell their friends about it.

We recently asked our subscribers to send us the names of those whom they believed the Scientific American would interest, and we are gratified to find that so many of our subscribers believe that its merits will appeal to such a large number of their friends. Have you sent a list? If not,

Here is the way:

Simply send us the names and addresses of the people whom you think will be interested and we will do the rest. An accurate record of all names received in this manner will be kept, and for each new subscription we get from any list we will extend the subscription of the person who sent us the list for four months. Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year.

Of course you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own subscription will be renewed.

Be careful to write the names and addresses plainly and don't fail to put your own name and the address at which you are receiving the Scientific American on each list you send.

Address all lists to Circulation Department, Scientific American, 361 Broadway, New York.

Holiday Suggestions in Useful Books

The Scientific American Boy

By A. RUSSELL BOND, 12 mo., 317 pages, 340 ill. Instructions. Price, $2.00.

This is a fascinating story of another boy Bill, and contains a number of practical suggestions to all boys. In the amusement, will stimulate in boys the creative spirit. In addition constant practical instructions are given for building the various articles. The boy scout is supplied with notes for making tramping outfits, camping huts, tents, tree shelters, snow huts, log cabins, and caves. Water diversions include instructions for making skate sails, snow shoes, ice boats, canoes, rudders, windmills, water wheels and the like are also described. It attractively illustrated with half tones from life and numerous diagrams and engravings drawn to scale.

The Scientific American Boy at School

By A. RUSSELL BOND, 12 mo., 396 pages, 514 illustrations. Price, $2.00

This is a sequel to "The Scientific American Boy," and like its predecessor is brim full of practical suggestions, which are entirely new. The construction of the apparatus described is within the scope of the average boy, is fully described and the instructions are interesting as to the boy. While the book is interesting as well as instructive to the boy. The evident continue instructions on engraving, printing and drawing, the building of dams, canals and canal locks, wave motors and several different types of boats, wireless telegraphy, compressed air, electric machines, the photography and camera shooting are a few of the other interesting subjects taken up. Other popular titles are Boy Electrician, Handi-craft, Handy Man's Workshop, Boy Inventors, etc. The boy of a mechanical turn of mind can read this story without being inspired to try his hand at making the devices.

Experimental Science

ELEMENTARY PRACTICAL AND EXPERIMENTAL PHYSICS

By GEORGE M. HOPKINS. 2 volumes, octavo, 1100 pages, 900 illustrations. Price in cloth, $5.00; half morocco, $7.00.

This work treats on the various topics of physics in a popular and practical way. Its object is to afford to the student, the amateur, the mechanic and in fact all who are interested in science, whether young or advanced in years, a ready means of acquiring a practical knowledge of physics by experimental method The leading principles of physics are illustrated by simple and inexpensive experiments and the endeavor has been made to make the explanations of both scientific and experimental plain and easily understood In the new edition, the scope of the work has been broadened and it now treats the more recent developments in modern science. It presents the more recent developments in modern science and gives much information which will assist the reader in comprehending the great scientific questions of the day

Magic, Stage Illusions and Scientific Diversions

Compiled and Edited by ALBERT A. HOPKINS. Large octavo, 536 pages, 400 illustrations. Price, $2.50

This work appeals to old and young alike, and is entertaining throughout. In the preparation of the standard works on magic, the Editors are all familiar with those which have proved most popular and practical. Great attention is paid to the amount of time and money required for the making of apparatus. Many have been furnished by the manufacturers themselves. Some of the most important tricks of Robert Houdin, Hamilton Cochran, Keller and Hermann the Great, with original tricks have not been neglected, a selection of some of the best of these various feats is given. Sleight of hand, ventriloquism, impersonation—all come in for a share of attention, while mental magic, electric magic, wire performances, illusions, mechanical magic, trick photography, illusions, common tests and many others are well described and illustrated.

Handy Man's Workshop and Laboratory

Compiled and edited by A. RUSSELL BOND. 12mo., 467 pages, 370 illustrations. Price, $2.00.

This is a compilation of hundreds of valuable suggestions and numerous plans for the mechanic and those mechanically inclined, and will be of help to all who do work with tools—both skilled and unskilled. The suggestions are practical, and the estimates by which they refer are of important importance. It may be regarded as the best collection of ideas of resourceful men for practical and economical use, and will find a place for itself in the home or workshop. The book is fully illustrated, in many cases with working drawings, which show clearly how the work is done.

Home Mechanics for Amateurs

By GEORGE M. HOPKINS. 12mo., 370 pages, 330 illustrations. Price, $1.50.

This is a thoroughly practical book for the most novel and clear explanations in regard to the use of tools, wood working, metal working, machine tools, metal working, sheet metal working, forging, soldering, modeling, pattern making, founding, foundry equipment, machine shop practice, pipe fitting, brazing, gas engines, electric motors, dynamos, electric bells and an electric furnace, and many other useful articles for the home and workshop. It appeals to the boy as well as the instructive amateur and tells how to make things the right way, no useless expense.

Any of these books will be sent post-paid on receipt of advertised price

was stricken with pneumonia while on a business trip in the West and the end came very unexpected.

Mr. Haskins was born in Waltham, Mass., May 22nd, 1867, and was educated in England where he specialized in mathematics and physics and took a special course in surveying and fortification work. In 1888 he entered the employ of the S. Z. de Ferranti & Company as one of its junior assistant engineers, where he had charge of the manufacture of electrical meters and assisted Mr. de Ferranti on the drawings for the original Deptford electric light station

In the autumn of 1889 he was a designing draftsman in the Thomson Electrict Welding Company, Lynn, Mass Two or three months later he was employed by the Thomson-Houston Electric Company, Lynn, Mass., as an electrical engineer. In 1891 he was appointed manager of the Meter Department of this company and after its consolidation with the General Electric Company, Mr. Haskins retained this position, including general supervision of the engineering and the manufacture of instruments

At the beginning of the Spanish-American War Mr. Haskins proffered his services to the government and organized a corps of electrical engineers and men trained in electrical work, of which he was made commander In the laying of the submarine mine defenses of Boston Harbor, the erecting of search light and ranges finding stations and other similar work during the war, Mr. Haskins and his command gave valuable service He also gave invaluable aid in an advisory capacity in connection with other defense work on the north Atlantic coast Under his supervision the temporary generating stations at Fort Warren and Fort Nahant were erected as well as all the range finding and communicating stations on the New England coast The work in Boston Harbor involved the charging and laying of some 200 mines. At the conclusion of the war, Mr Haskins resumed his position with the General Electric Company He had made a special study of electricity as applied to offense and particularly defense in time of war and was considered an authority on this subject. After the close of the war he frequently acted in an advisory capacity to the government in matters of this nature

Mr Haskins was a member of the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, of the National Electric Light Association, and associate member of the Military Service Institute and the U. S Naval Academy

NEW BOOKS, ETC.

PHYSIKALISCHE ZEITSCHRIFT 12 Jahrgang 1911. Seite 540-546. Struktur und Optik grosser Kristalltropfen Von O Lehmann.

KONISCHE STRUKTURSTORUNGEN BEI FLUESSIGEN PSEUDOKRISTALLEN Von O Lehmann Sonderabdruck aus den Verhandlungen der Deutschen Physikalischen Gesellschaft. XIII. Jarhgang Nr 8 Braunschweig Druck von Friedr Vieweg & Sohn, 1911

UBER MOLEKULARSTRUKTUR UND OPTIK GROSSER FLUESSIGER KRISTALLE Von O Lehmann Separat-Abdruck aus den Annalen der Physik Vierte Folge Band 35 Leipzig Johann Ambrosius Barth, 1911

DIE UMWANDLUNG UNSERER NATURAUFFASSUNG INFOLGE DER ENTDECKUNG DES RELATIVITATSPRINZIPS Von Geh. Hofrat Prof Dr O Lehmann, Karlsruhe Vortrag gehalten im Karlsruher Naturwissenschaftl Verein am 2 December 1910

DAS RELATIVITATSPRINZIP DER NEUE FUNDAMENTALSATZ DER PHYSIK. Von O Lehmann Sonderabdruck aus dem 23 Band der Verhandlungen des Naturwissenschaftlichen Vereins Karlsruhe Druck der G. Braunschen Hofbuchdruckerei, 1910.

These publications contain careful studies of Prof Lehmann's investigation of liquid crystals. If there can be any doubt that our definition of the word "crystal" must be revised, surely Lehmann's work must dispel it

DER MENSCH DER VORZEIT. Von Wilhelm Bolsche. Stuttgart: Kosmos, Gesellschaft der Naturfreunde, 1911.

In this simply worded book the author gives the more important results of modern research on the subject of prehistoric man.

Complometer
ADDS MULTIPLIES SUBTRACTS DIVIDES

"Say Mr. Jones, the bill clerk is ready to begin extending his bills and he wants the Comptometer"

"Tell him he'll have to wait until I finish checking my postings."

"All right, but how about Mr Brown—he says to tell you he's been holding up some percentage work for two or three days, waiting for a chance at the machine?"

"Well, I won't keep it long, but there's nothing doing until I get through."

—This is typical of what happens in offices where they understand the Comptometer—where its value has been demonstrated by use on all kinds of figure work—addition, multiplication, division and subtraction.

It won't cost you anything to have a Comptometer put in your office on trial Write us about it.

For Universal Service

The Press and the Bell System

The power of the individual writer is multiplied by the printing press In the same way the power of the individual telephone is multiplied by the Bell system. In both cases, increased usefulness comes from progress towards universal service.

By means of the press the knowledge and thoughts of writers are spread throughout the land, maintaining among all the people the common language and the mutual understanding which makes for national co-operation.

By means of the Bell system, each individual telephone becomes connectable with every other telephone and each unit in the nation is given a personal membership in the most highly developed system of communication that the world has ever seen

The press prepares people for co-operation; the Bell telephone system enables them to really co-operate. The press educates people separately; the telephone enables them to act upon their mutual knowledge immediately and at any distance.

By co-operation with telegraph and cable systems, universal service for communication is being made international.

ANNUAL MOTOR NUMBER

MOTOR CARS MOTOR TRUCKS MOTOR BOATS MOTOR CYCLES

JANUARY MAGAZINE NUMBER OF THE SCIENTIFIC AMERICAN

ISSUE OF JANUARY 6, 1912

Although we are well past the dawn of the "hydrocarbon age," we have not yet reached the meridian period. Each year there are new developments making for the betterment of motor-driven land and water vehicles. The improvements that are to be brought out in 1912 are exceptionally interesting and will be outlined in detail in this number. The following articles will appear:

Selection of a Motor Truck

In what respect do leading types of motor trucks for 1912 differ mechanically? How can the owner best protect his investment? What are the costs of upkeep and operation as compared with those of horse-drawn trucks? Can truck chauffeurs be made of ordinary teamsters? These are vital questions to the intending purchaser of motor trucks, which will be ably discussed.

Will Rubber Tires be Supplanted?

While tire manufacturers are doing everything that is humanly possible with rubber and fabric, yet, undoubtedly, there is no feature of a motor car that gives the owner more concern than the tires. The ability of rubber to stand up under the terrific shocks and wearing grind of service is a marvel. Hundreds of inventors have been busy at the task for years, no substitute for the rubber tire has yet been developed to such a degree as to supplant the standard pneumatic tire. Just what has been done in the past, and what promises are held for the future, will be brought out in this article.

The New God of War—Gasoline

In this article the prominent place occupied by the automobile in European military maneuvers is described. In the United States the armored automobile has been entirely neglected. In Germany in time of war every car in the country, private as well as public, is placed at the beck and call of the Government.

Auxiliary Uses for Motor Vehicle Engines

Herein are described a number of novel uses for the engine of a motor truck or an automobile.

The Comparative Cost of Light and Heavy Cars

This question is debated by a man who has made painstaking and impartial comparison of every detail of his personal expenses in connection with two cars, one a typical light car, and the other a standard heavy car.

Making the Starting Crank Obsolete

One of the most noticeable features of the 1912 car will be the absence of a starting crank in front of the radiator. The desirability of providing a means for starting the car from the driver's seat was expressed years ago, and its necessity has been urged more clamorously each year. Now, suddenly, a score of different self-starters have been developed, and the majority of manufacturers are going to bring out their 1912 cars with some sort of a self-starting mechanism. The leading types of self-starters will be explained so that any automobile owner can understand them.

Driving the Car at Night

To obtain the full value of a motor car, it must be available for service at night as well as during the day time. There is much more to safe night-riding than a pair of powerful headlights. There are new developments which every automobilist should know.

The Easy Riding Car

The pleasure vehicle has now become so standardized that the riding qualities of an automobile receive much more attention than heretofore. As a consequence, designers have been devoting much thought to the springs, shock absorbers, upholstering, the balance and hang of the body, and all the features that enter into the making of a comfortable car. The prospective purchaser should know that the distribution of weight on a car is an important factor in making it "stick to the road." A badly-balanced car will possess poor traction qualities owing to the tendency of the rear wheels to bounce off the road's surface.

A Fertile Field for Inventors

Under this subject are detailed many ingenious devices that inventors have developed of late for use on automobiles.

Lessons in Everyday Motor Boat Designs

The racing motor boat is very properly considered a useless craft for pleasure purposes. In the present article, however, it is clearly brought out that the design of the pleasure boat has been materially improved by the development of the racer.

Motor-Cycle Developments

What is being done to improve that noisy, sputtering, two-wheeled vehicle? Among the prominent features for 1912 are footstarters, multiple jet carbureters for slower running in cities, improved mufflers, and floating seats to make riding more comfortable.

Navy Yard Politics

TIME was when the navy yards of this country were dominated by the politician. During the last two decades they have gradually been emancipated from political interference, and, but for recently-enacted legislation, it would have been possible to say that the work of upbuilding of our navy, both at the yards and by private contract, was proceeding without let or hindrance. But, unfortunately, certain hasty and ill-considered legislation by Congress in 1910 and 1911, passed in the interests of navy yard labor, has so seriously handicapped the private shipbuilders, by whom, of necessity the larger part of our new ships must be constructed, as to discourage them from bidding upon government contracts, thus most seriously threatening the future development of that arm of the service upon which the United States must depend for its future security and permanence.

We refer to the eight-hour law, which renders it obligatory upon contractors for new ships to limit the hours of labor upon ships built for the government to eight hours a day.

The law of 1910 was extremely vicious and objectionable in its effect, and the 1911 law goes far beyond it, in that it is so indefinite in its terms that it is impossible to tell how it would be interpreted by the courts. Furthermore, failure to comply with it automatically stops all payments for the work in progress, leaving the contractor to face the probability of long and expensive litigation, with uncertainty as to the outcome, before he may or may not receive the contract price of the vessel. The present law, as it is written, is vicious as to form and indefinite as to terms.

In regarding the law in its broad economic aspects, there are many sides of the subject that should be considered. In the first place, the government is not merely making a general law applicable to all of the material that it purchases, in fact, in the manufacture of these same ships that are to be built by eight hour labor, all of the armor and a large part of the guns, the ammunition and the outfit, all of the electrical auxiliaries, the steel plates and shapes, and other parts entering into the vessel that are not built by the shipbuilders, will all be constructed without restriction as to hours of labor.

Nor is any attempt made to limit the hours of labor of the manufacturer of the shoes and other clothing for the army and the navy, the manufacturer of the paper and other supplies used in all of the departments of the government, or any one of the other general supplies, but shipbuilding is singled out as the one industry that shall be assaulted by the powers in Congress.

Every one of the large shipyards in this country is engaged both in merchant and naval work, and, most of them, in other lines of manufacture. It is everywhere recognized as a practical impossibility to run different hours on different jobs in the same plant. It is not possible to build a merchant ship on one slip, where all laboring men and mechanics are employed from seven to six with an hour at noon; while on the slip next to it there is building a government ship, upon which the men work from eight to five, with an hour at noon; nor, in a machine shop, can one-half of the tools be started at seven, to work until six on merchant work, while the other half are started at eight to work until five on government work.

While it may be possible, by various subterfuges, to avoid the present wording of the law, this would merely mean a change, when the next naval appropriation act is written, to more closely tie the hands of the contractor; with the ultimate result of either forcing him to entirely abandon government work, or to place all of the work in his yard on an eight-hour basis. Let us observe the results of these two contingencies.

If government work is abandoned, he is then no longer restricted by the requirements of any law that may be passed, but he has given up what is to every large shipbuilder in this country so important a percentage of his business as to render his very existence uncertain, and the effect might be to oblige many of the shipyards to close their gates. This would mean that all naval work must be done at navy yards, a consummation most thoroughly in accord with the desire of the large group of navy-yard-labor politicians. This, however, would result in an increased cost of the ships of our navy of not less than forty per cent, as is clearly shown in the case of the "Florida," which has cost for direct labor and material nearly $6,400,000, as against the purchase price of the sister vessel, the "Utah," built by private contract, of about $4,000,000.

If, on the other hand, the shipyards accept the second contingency and proceed on a strictly eight-hour basis, they are then at a great disadvantage in their competition for other than government work. In all of the shops where tools are worked, the decrease in production due to the shorter hours will be directly in the proportion to the time, or a decrease of twenty-five per cent while the wages of the men will unquestionably (as every manufacturer of experience knows) be increased, so that their yearly income will be unchanged—a further burden on the cost of production of twenty-five per cent. In other parts of the works, where labor is of a different character, by working piece-work prices, it is probable that the production in eight hours can be brought up nearly to the standard of ten hours; but the ultimate result will be an increase in the cost of the labor entering into the production of by twenty-five to ten per cent, according to the character of the work. How much this means in merchant work or repairs, or in the miscellaneous work done by practically all of the shipbuilders in competition with other manufacturers, needs no careful argument to explain.

Where the government is concerned, it will mean, as it already has in the case of the "Texas," a very considerable increase in the contract price, and this, in effect will amount to a direct *subsidy* to labor by a government that has repeatedly rejected the subsidy idea when applied to helping the shipbuilding and shipowning industries of the country.

While many other arguments may be urged, we believe that the above outlines the principal ones that should be kept clearly in view in the consideration of the present anomalous condition, in which Congress singles out one particular industry, struggling with unremunerative conditions, and harasses and burdens it with the effects of an indefinite and ill-designed law, applicable only to work done for the government, while at the same time it passes by the greater and stronger industries of the country, which supply yearly to the government, directly or indirectly, many times more in value than do the shipbuilders. As matters now stand, both parties in Congress willingly subsidize labor on shore to the amount of $8,000,000 annually, but steadily refuse to subsidize labor working on the high seas a single penny.

A Ray of Light in the Darkest Province of Chemistry

WE have in our day a vast army of trained scientific workers, and methods of research have been so far standardized that practically any man of sound intellect and reasonable dexterity can turn out original work, provided he receives the right training and possesses the requisite determination and perseverance. But while there is thus going on a general filling out of the gaps in the existing network of our knowledge, it is given to comparatively few to do something far more than this, to open up an entire new field along an untrodden path, by methods specially devised for the purpose. It is such achievements as this which distinguish the great dominant spirits of science, the Newtons, the Maxwells, and Pasteurs. The works of such men, as we look into the past, stand out like milestones along the avenue of the progress of science through the ages.

In such a retrospect men and events naturally in their right perspective. It is more difficult to gage correctly contemporary tigators and results. Yet we would hardly he to point to Sir J. J. Thomson, of the Cave Laboratory, Cambridge, England, as a man name will stand on the records of the history o ence side by side with the greatest lights of the For his work far overtowers that of most of contemporaries, through the wealth of entirely and fruitful concepts which he has introduced modern science by ingenious experiment and a analytical and synthetic reasoning. It is thus he has given us an entirely new horizon by work on the corpuscular structure of the a which not only seems to reveal to us the true n of one of the most recondite forces inheren matter—chemical affinity—but which links into monious union such fundamental natural phenom as the mass-inertia of matter and the self-induc inertia of an electric charge.

The latest product of the fertile mind of t great genius seems destined to throw light on t darkest chapter in the field of modern chemistry. We have hitherto rested content with the study of chemical substances in that state in which we find them either before or after a reaction has taken place. To ask, what is the nature of matter during the intermediate stages of the process of chemical transformation, would until recently have been regarded almost as an impertinent question, except perhaps when it came from the lips of such an eminent chemist as Schonbein. Yet it is this question which, among others, Sir J. J. Thomson seems to have found the means of attacking by direct experiment. By measurements of the deflection of positive rays in a vacuum tube containing traces of various substances, it is possible not only to identify the elements and compounds present, but at the same time to determine their atomic and molecular weight. Furthermore, since the rays are registered within less than a millionth of a second after their formation, if chemical action is going on in the tube, it is to be expected that the method should disclose transient forms of matter intermediate between two chemical compounds, and thus shed light on the true nature of the process of chemical combination. And experiment bears out this expectation. In a tube originally charged with marsh gas, Sir J. J. Thomson has detected products of molecular weight 12, 13, 14, 15, and 16, corresponding to molecules having one, two, three, and four hydrogen atoms attached to the carbon atom. These represent the several intermediate stages in the formation of the complete marsh gas molecule, and we have here the first positive observation of such half-formed molecules.

It is probably not too much to say that these experiments, of which an illustrated note appears on another page of this issue, usher in a new era in the history of chemistry.

A Record Rainstorm in the Philippines

THREE great typhoons occurred in or near the Philippines last summer within a period of three weeks, viz., July 11th-17th, July 20th-27th, and July 30th-August 2nd.

The maximum rainfall occurred at Baguio—the official health resort of the Philippines. This place is 4,777 feet above sea-level and is normally one of the wettest spots in the islands, with an annual rainfall of 157.52 inches. Never before, however, had such a torrential downpour occurred here as on the four days July 14th-17th, 1911. The daily amounts, as recorded by a self-registering gage, were: 14th, 34.64 inches; 15th, 28.88 inches; 16th, 16.73 inches; 17th, 7.89 inches—a total for the four days of 88.14 inches!

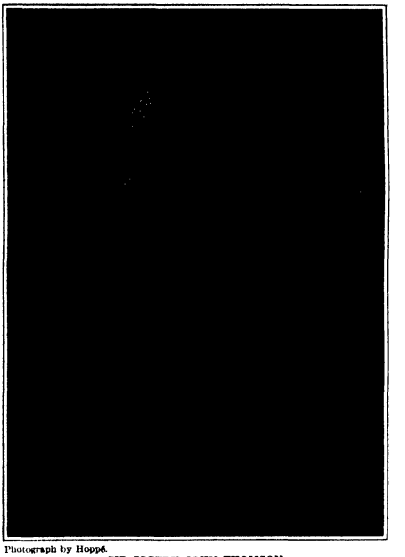
For a period of four days this record had rarely been equaled in the history of meteorology. In average intensity, however, this storm does not quite equal one that occurred at Cherrapunji, in the Khasi hills of India—a place well known to meteorologists as the wettest spot in the whole world. Here during the five days June 12th-16th, 1876, fell a total of 114.14 inches of rain, distributed as follows: 12th, 30.45; 13th, 7.75; 14th, 40.80; 15th, 22.84; 16th, 12.30. It so happened that the maximum in *four* days was a little less than Baguio's record for a like period, viz., 88.69 inches.

Both these records were, however, eclipsed by that of a rainstorm that occurred in the mountains of eastern Jamaica, in November, 1909. At a place called Silver Hill the fall—if correctly measured—amounted to 135 inches in eight days, of which 114.50 fell in five days; 96.50 in four days, and 37.50 in two days. That these figures are at least approximately correct is shown by the records of surrounding stations.

Sir Joseph John Thomson, the Great English Physicist

The Originator of the Corpuscular Theory of Matter

By P. Phillips, D.Sc., B.A., Professor of Physics at the Royal Veterinary College, London



THE Cavendish Professorship at the University of Cambridge, England, of which Sir J J Thomson the present holder, is a post of honor to which his predecessors have lent no ordinary luster The first der of the office was James Clerk Maxwell, the found original genius who laid the foundations for modern electro-magnetic theory associated with name. The second Cavendish Professor was Lord leigh, whose measurements of the fundamental ntities of physics are among the most beautiful accurate experiments ever performed The third be called to the chair was Sir J J. Thomson, who s proved himself in every way worthy of his prede- ssors.

He was appointed while a young man in his twen- y-seventh year—a very early age for so responsible position—and his appointment was severely criti- cised by some of the older and more orthodox pro- fessors and tutors One well-known college tutor expressed the opinion that things had come to a pretty pass in the University when mere boys were made professors But the Board of Electors, including Sir William Thomson (Lord Kelvin), Prof G G Stokes and Prof G H Darwin, knew what it was doing, and the bold appointment has been amply justified by the continued advance of the Cavendish Laboratory and by the posi- tion which Sir Joseph has attained among his contemporaries

His early training Sir J J Thomson re- ceived at Owen's College, Manchester, where he was a student in 1876, and carried out some experimental work under Prof Bal- four Stewart. He thence proceeded to Cam- bridge, where he read mathematics until taking his tripos in 1880 From this time dates his connection with the Cavendish Laboratory, which was later to become so intimate and prolonged He was appointed to his present position in 1884 Perhaps when the lapse of time shall enable us to see things in a truer perspective, we shall con- sider that his greatest service to science has been the building up and inspiring of the center of research at the Cavendish Labora- tory. When he was first appointed there were not more than seven or eight students engaged in research, while at the present time the number has risen to about thirty, and the mass of work emanating from this scientific center is a splendid testimony to the enthusiasm and ability of the men gath- ered there

To give an account of any great man's work within the limits of a short article is always difficult, but it is unusually so in the present case, for Sir J. J Thomson is so continually overflowing with ideas, that his contributions to science are extremely varied and numerous It must suffice here to men- tion only a few of the larger pieces of work which he has carried out In 1881 appeared on the Adams Prize Essay a mathematical treatise on the vortex theory At that time the theory that atoms were vortices in the ether was very popular and sev- eral well-known names were connected with it, it had very little to recommend it, however, and since a bet- ter understanding of the phenomenon of the discharge of electricity through gases has given us more intimate information about the atom, the vortex theory has lapsed into a well deserved obscurity Neverthe- less the treatise formed a most valuable contribution to the general theory of vortices and showed some of the serious difficulties which would have to be over- come before the vortex theory of the atom could be accepted. Appropriately enough, one of Sir J J Thom- son's earliest experiments was the repetition of a measurement which strongly supported Maxwell's elec- tro-magnetic theory, namely, the determination of the ratio of the electro-static to the electro-magnetic unit of electricity. This was found to be equal to 3×10^{10}, a figure closely agreeing with the measured velocity of light expressed in centimeters per second This result is one of the conclusions which Maxwell derived from his theory, which thus received strong corrobora- tive evidence. Further confirmation was furnished in 1887 by the brilliant work of Hertz in demonstrating the existence of the electro-magnetic waves which Maxwell's theory foretold, and since then these waves have become a matter of every day talk by the devel- opment of wireless telegraphy The next important work published by Sir J J. Thomson was a series of papers published in the Philosophical Transactions of the Royal Society in 1886-1887 (and republished in book form in 1888) on "The Application of Dynamics to Physics and Chemistry" This work suggests a number of general methods of attacking chemical and physical problems which have proved most useful Their greatest value lies in the fact that they can be applied even where very little is known of the inner processes going on

A very important experiment was carried out in 1889, when Sir J. J Thomson devised a method of find- ing the specific inductive capacity of different sub- stances for very rapidly alternating electric forces This experiment was of considerable interest owing to the fact that Maxwell's calculations of the velocity of light in different substances, as dependent upon their

Photograph by Hoppé.

SIR JOSEPH JOHN THOMSON

specific inductive capacity, gave results considerably at variance with the observed values in certain cases Sir J J Thomson suggested that the discrepancy might be due to the fact that the specific inductive capacity of a substance for rapidly alternating electric forces, such as occur in light waves, differed from that found for steady electric forces in the usual way Experiment completely bore out this suggestion, and added one more link to the chain of evidence in sup- port of Maxwell's theory

After this followed a long series of experiments on the conduction of electricity through gases, which, along with the work of Schuster and others, has gone far to clear up our understanding of the mechanism of this complicated phenomenon In 1898 these experi- ments culminated in the discovery of the "electron," or as Sir J. J Thomson himself calls it, the "cor- puscle" This discovery has ushered in a new era in science, and has opened out a vast realm for new work upon the development of which some of the great physicists and mathematicians of the day have spent their best efforts It is unfortunately quite impossible within the scope of this article to give even a remote idea of the bearing of this work, only one or two points shall be mentioned with which the name of J J. Thomson himself is associated The picture of the atom which Sir Joseph would present to us is that of a large number of corpuscles, assembled together into a minute planetary system in which the corpuscles play the role of planets, revolving in concentric rings From considerations of the stability of such rings he has suggested an explanation of the existence of series or groups of elements with similar properties, thereby taking the first step in lifting the veil from the mystery of Mendeleeff's Periodic Table of the Elements Furthermore, by calculating the period of vibration resulting from various distortions of such rings of cor- puscles he has also suggested an explanation for the existence of series of lines in the spectra of different elements Since this conception of the atom was first put forward by Sir J J Thomson, it has been found that some elements are continually breaking down ejecting corpuscles, and giving rise to other elements as transformation products

Had the old idea of the indivisible atom still remained, this would have presented an almost insolu- ble problem, but with the new view of the atom it becomes perfectly simple Breaking down the atom is simply knocking off some of the outer rings of corpuscles leaving the inner rings intact and it is evident that such a process must be accompanied by the ejec- tion of corpuscles unless the rings which are knocked off reform themselves into a new system with exactly the same number of cor- puscles as are broken off the parent atom

Since that time Sir J J Thomson's main experimental and theoretical work has been concerned with the further working out of the problems presented by the conduction of electricity through gases, and with the con- stitution of the atom, but space does not permit of the presentation of his work in further detail

As a teacher he exerts a most inspiring influence upon his students making himself one with them and making them feel that he and they are engaged upon a common quest This sympathy with his pupils is probably the secret of his power but he has other qualities which are very valuable to his students His happy way of working things up from first principles and thus recalling the strong and weak points in any theory is most suggestive clears up a man's ideas and is most excellent preparation for future research work To observe his use of mathematics is an education in itself Sir J J Thomson is never led away into those pretty mathematical by-paths so dear to the heart of the orthodox Cambridge mathe- matical physicist He selects such mathe- matics as is required for his investigation and then marches straight ahead for his goal in a most convincing fashion He is always the physicist first and the mathema- tician after As leader of the research stu- dents at the Cavendish Laboratory Sir Joseph is the most approachable and helpful of men Although his personality dominates the laboratory yet there is splendid freedom from restraint and a wonderful encouragement to carry out research on any subject His visits to any par- ticular student may be somewhat spasmodic but this is quite in keeping with some other little eccentricities which are well known to all his students and which no doubt lose nothing in the telling At tea which he provides every afternoon in his room for all the research students J J as he is always called is perhaps at his best At this time all the gossip of the laboratory passes around and a story has to be a pretty tall one if he does not manage to cap it J J 's vigorous radical utterances are also very warmly dis- cussed, and not infrequently among the cosmopolitan collection of students the political discussions become both interesting and very animated

In this article the endeavor has been simply to show Sir J J Thomson as a man of science and the head of a famous laboratory Of the many honors showered upon him, culminating in the award of the Nobel prize in 1906, and the bestowal of Knighthood in 1908, and of his home life, nothing has been said, but the writer hopes that enough has been told down to make the reader join him in the wish that J J may be long spared to extend the limits of our knowledge in that section of natural science which he has made peculiarly his own, and in which he has labored with such brilliant success, giving to the world the priceless gift of his genius, and earning imperishable fame.

Chart showing the travel of Mars and Saturn across the heavens during equal periods of time, from June 1st, 1911, to March 31st, 1912.

The Motions of Mars and Saturn

Apparent Meanders of Two "Wandering Stars"

By Prof. S. A. Mitchell, Columbia University

IT needs but a casual glance to see that Mars is now the brightest object in the evening skies, it needs but a few evenings' watch even for anyone not acquainted with the stars, to note that Mars is a "wandering star," as the Greeks called it, a planet By making a diagram giving the position of Mars with respect to the neighboring stars, it will be easily seen, after a few nights' watching, that Mars is now moving toward the west among the stars The first week in December found Mars due south of the Pleiades and but a few degrees away from them It continues to move west only until the 29th of December, when it ceases its westward motion, becomes stationary, and then moves east at first slowly, and then with increasing pace

To the west of Mars is Saturn the wonderful, a never-ending source of pleasure to the amateur with his small telescope It, too, is changing its position among the stars, but with a satellite mien owing to its increased distance from us Saturn, too, at the present time, is moving toward the west, but it keeps on moving west until after the middle of January, 1912, when it becomes stationary, and then moves also to the east

The amateur who likes to watch the sky will find a great deal of profit from noting the motions of these two planets relation to the stars The accompanying diagram shows the motion of Mars from June 1st to March 31st and that of Saturn for the same interval, from the first of January to the end of March A glance will show that Mars 'retrograded,' or moved to the west from October 17th to December 19th, while Saturn moved backward on its path for a longer time, but through less angle, from 1911, September 2nd to 1912 January 16th Another glance will show that Mars has three times passed by the Pleiades first at the end of August when it was six degrees to the south of them, for the second time during the first week in December Toward the end of January will occur the closest of all three approaches, when it again passes to the south By following the diagram backwards, it will be seen that on August 15th, Mars and Saturn were very close together As a matter of fact on August 16th at 11 P M Mars and Saturn were separated by only twenty-one minutes of arc, which is an angle equal to two-thirds of the moon's diameter, Mars being north of Saturn On the same night, a few hours later, the moon was in the same part of the sky, passing to the north but four degrees away This interesting conjunction has been magnificently portrayed by the accompanying photograph taken with the six-inch Bruce telescope by Prof. E E Barnard of the Yerkes Observatory This was taken on the morning of August 17th at 3 14 o'clock with an exposure lasting twenty seconds It is a remarkable photograph in that it shows the dark portion of the moon in the last quarter illuminated by "earth shine" The planet nearest the moon is Mars.

After the date of this photograph, Mars was moving rapidly eastward while Saturn soon slowed down and then moved westward By October 17th, the planets were separated by 25 degrees, when the change in the motion of Mars again began to lessen the distance They will be nearest each other about New Year's, after which the eastward motion of Mars will again cause the distance to increase

As everyone knows, the apparent motion of the planets is caused by the motion of the planet about the sun combined with that of the earth The relative motion of Mars, for instance, may be correctly represented by supposing that it has two motions, one its own motion, and superposed on this another, equal in

Conjunction of Mars, Saturn, and the Moon, 1911, August 16, 15h. 14m. C. S. T.

magnitude to that of the earth's motion about the sun, but in the opposite direction This simple fact explained in detail in every text book on astronomy need not further be elaborated here

A Type of High-intensity Primary Cell

By Dr. Alfred Gradenwitz.

A NEW high-intensity primary cell invented by H. D. P. Huizer of The Hague owes its high efficiency mainly to the fact that the carbon and zinc are located as closely to each other as possible, the carbon having a grooved surface through which the ions can be discharged easily and rapidly. Wherever these ions after their discharge result in polarization, the apparatus is so designed as to produce immediate depolarisation by chemical and mechanical effects, so that the ions coming afterward may be free to discharge on the poles. The high current density and short distance between the carbon and zinc also warrants a uniform and economical dissolution of the metal. At a recent test the electromotive force in open circuit was found to be about 1.95 volts and the working tension with weak currents (up to 1 ampere [0.065 per square inch] per square decimeter electrode surface) about 1.8 volts, with high-intensity currents (up to 5 amperes [0.32] per square inch) about 1.6 volts and with maximum current densities (up to 0.65 amperes per square inch) about 1.4 volts Current rushes and even short-circuits (up to about 2 amperes per square inch) with tensions reduced in proportion, were found to exert no objectionable action on the cell; the internal resistance was very low (down to 0.01 ohm)

Ten incandescent lamps of a total of 26-27 candlepower could be fed permanently with a single cell. The consumption of zinc with diluted sulphuric acid was found to be 1.7 grammes per ampere-hour (the theoretical electro-chemical equivalent being, of course, 1.22 grammes per ampere-hour). The useful current effect was found to be 70 per cent, so that 1 kilogramme of zinc (and 1½ kilogrammes of sulphuric acid) will be amply sufficient to develop 1 horse-power-hour, the current expenses only being about 16 cents, viz., 1/10 of that of ordinary primary cells The depolarising capacity is so remarkable that one-fourth minute suffices for the cell to recover its maximum tension after a short-circuit.

It will be readily understood that these results constitute a remarkable advance over primary cells so far in general use. While the output of common stationary storage battery cells for each kilogramme of their own weight is 10-15 watt-hours and that of the portable accumulators 25-30 watt-hours, the new cells allow outputs of 30-50 and those designed for transportation operation as much as 100 watt-hours. In connection with a special type of cell the inventor is even able to insure 200 watt-hours for each kilogramme of cell weight.

In a test of an electric vehicle equipped with the new cells the current expenses worked out at about 3 cents per ton mile. With a single supply of zincs (about 330 pounds) and several re-fillings of acid, the vehicle covered a distance equal to that between the Hague and Paris (about 300 miles) at an average speed of 18 miles per hour. The new cell would moreover seem to lend itself to the propulsion of electric cars and airships.

The new cell is made in two different types. In connection with the tests described above concentric cylinders were used. However, in order even further to reduce the consumption of zinc, a special type of "parallel" cell has been designed in which the carbon surface is likewise increased to a maximum by ribs, though not in the shape of cylinders but of flat plates. The zinc, so far from constituting a homogeneous mass, assumes the form of minute disks performing an automatic motion by which their distance from the carbon is kept constant, insuring a uniform work.

Powerful Electromagnet for the Use of Oculists

A Convenient Form of Apparatus for Extracting Iron and Steel Splinters

By C. Van Langendonck

...ne electromagnet designed for the use of oculists ... by Dr. Haab, director of the Zurich eye clinic, and ...wn in the accompanying photographs, is the most ...werful and efficient apparatus of this kind in exist... According to Dr. Haab, the principal require... of such an instrument are the following:

1. The magnet must be capable of developing very ...t tractive force.

2. It must be placed horizontally, and its circuit ...t be made and broken by the operation of a pedal.

3. The working pole must have a form adapted to ... peculiar function and its dimensions must bear the ...per relation to those of the coil.

The first condition is very important. The small ...ectromagnets which are commonly used by oculists ...ften fail at the critical moment, owing to their lack ...f adequate magnetic strength, and thus endanger the ...uccess of the operation.

The method of making and breaking the circuit by ...the foot of the operator possesses great advantages, ...because it leaves both hands free for the control of ...the eye and body of the patient, and makes it unneces...sary to remove the magnet in order to stop its action ...This last point is exceedingly important for, even with ...the most perfect suspension, it would be impossible ...to withdraw the heavy electromagnet from the eye ...quickly enough to prevent the iron filing or other ...foreign substance from being drawn into a region ...where its presence is not desired. When the circuit ...is opened and closed by a pedal the magnet need not ...be suspended.

Dr. Haab regards the suspension method not only as ...impracticable for the heavy magnets which he em...ploys, but as incorrect in principle. His experience ...proves that it suffices to support the magnet in such ...a manner that its axis can be turned to any direc...tion in a horizontal plane.

In regard to the form of the working pole, it is ...obvious that its action will be weakened in propor...tion to the extent to which it protrudes from the coil. ...It must not, however, be so short that the coil in...terferes with the view of the field of operation, as is ...the case in some of the newer large electromagnets.

The magnet is of the bell form. The working pole ...is a cone of 90 degrees, and this end of the coil is ...tapered sufficiently to give the operator a clear view ...of the field up to the tip of the magnet pole. Four ...pointed tips accompany each apparatus.

The idle pole is expanded into the form of a bell ...which covers and protects the greater part of the ...coil. This construction possesses the additional ad...vantage of restricting the escape of lines of force to ...one side and diminishing the area of the external ...magnetic field.

A set of pole points.

Foot-controlled electromagnet.

The magnet is mounted on a cast iron pillar, in such a manner that it can easily be turned in any direction. The pillar is hollow and is provided with castors, so that the apparatus can be moved without difficulty. The axis of the magnet is about four feet above the floor. At a little more than half this height a shelf is attached to the pillar for the purpose of supporting the patient's arms and keeping his head motionless during the operation.

The base of the pillar contains the electric switch which is closed by depressing a pedal and is thrown open by a spring the instant the foot is raised. A special device protects the contacts from injurious sparking. The current-density in the coil is very small in comparison with its density in other electromagnets. Hence very little heat is developed—a condition essential to permanent efficiency.

In tractive power Haab's electromagnet stands at the head of all known electromagnets used by oculists. At a distance of 1/2 inches, for example, it exerts a pull more than twice as strong as that of the largest Volkmann magnet.

The electromagnet is designed for use on direct current circuits of 60 to 300 volts, but it can be employed on alternating, uniphase or triphase circuits with the aid of a suitable transformer. The maximum power required is about one kilowatt. The total weight of the apparatus is about 286 pounds.

This apparatus, although designed primarily for the use of oculists, is admirably well adapted for the extraction of iron filings and splinters, hammer scale, etc., from wounds in any part of the body. Hence it may advantageously be installed in the hospital rooms of all large mining and metallurgical establishments. Experience shows that the magnets now employed in these rooms are used as often on hands and arms as on eyes. Wounds incurred in planing iron are often filled with fine splinters of iron. The removal of these splinters singly with pincers or needles is a tedious and painful operation, but all of the iron or steel particles can be extracted quickly by means of a powerful magnet.

A Seismograph in a Coal Mine

NATURE states that a seismograph has recently been installed in the Tunnel Colliery, at Nuneaton, for the purpose of ascertaining whether the apparently inexplicable falls of coal and roof in mines have any relation with the occurrence of earthquakes. Aside from the practical object in view, a comparison between the records of this instrument and those of instruments on the surface is likely to be of much scientific interest.

Frost Fairs on the Thames

LONDON winters are more remarkable for dismal drizzling rain and impenetrable fog than for snow and ice; but about half a dozen times in the last three hundred years truly arctic conditions have prevailed in that metropolis, and the River Thames has been frozen over so firmly that men and horses could go upon it. Each of these periods has been the occasion of a "frost fair"; booths have been erected on the ice; printing presses set up, various sports and games indulged in; and the whole population has joined in celebrating the rare event.

The first great frost fair was held in January, 1608; but the most famous of all was that of 1683-4, which lasted from the beginning of December to the 5th of February. Evelyn gives the following description of this fair in his "Diary": "The frost continuing more and more severe, the Thames before London was still planted with boothes in formal streetes, all sorts of trades and shops furnish'd and full of commodities, even to a printing presse, where the people and ladyes tooke a fancy to have their names printed, and the day and yeare set down when printed on the Thames: this humour tooke so universally, that 'twas estimated the printer gain'd £5 a day, for printing a line onely, at sixpence a name, besides what he got by ballads, etc. Coaches plied from Westminster to the Temple, and from several other staires, to and fro, as in the streetes, sleds sliding on skeates, a bull-baiting, horse and coach races, puppet-plays, and interludes, cookes, tipling, so that it seem'd to be a bacchanalian triumph, or carnival on the water." King Charles II. and his family visited the fair, and had their names printed on a quarto sheet of Dutch paper, which is still extant.

During the frost fair of January, 1716, it is recorded that an uncommonly high spring tide, which overflowed cellars on the banks of the river, raised the ice fully fourteen feet, without interrupting the people in their pursuits.

Similar fairs were held in 1740, 1788-9, and 1814. The last was one of the gayest and most animated of these events, though it lasted only four days.

Meeting of the American Association

THE sixty-third meeting of the American Association for the Advancement of Science will be held in Washington, December 27th to 30th, 1911, under the presidency of Prof. Charles E. Bessey, of the University of Nebraska. In conjunction therewith will be held the tenth of the "convocation week" meetings of affiliated societies, viz.: American Anthropological Association, Astronomical and Astrophysical Society of America, Society of American Bacteriologists, American Society of Biological Chemists, Botanical Society of America, American Chemical Society, American Civic Alliance, American Economic Association, American Association of Economic Entomologists, Entomological Society of America, American Fern Society, American Folk-Lore Society, Association of American Geographers, Geological Society of America, American Federation of Teachers of the Mathematical and the Natural Sciences, American Home Economics Association, Society for Horticultural Science, American Association for Labor Legislation, American Microscopical Society, American Nature-Study Society, Paleontological Society of America, American Physical Society, American Physiological Society, American Phytopathological Society, American Psychological Association, Sigma Xi, American Sociological Association, American Statistical Association, Sullivant Moss Society, Southern Society for Philosophy and Psychology.

The administrative headquarters of the meeting will be at the New Willard Hotel where all members will register, beginning at 9 o'clock, December 27th. The opening general session of the Association will be held at the U. S. National Museum at 8 P. M., December 27th. It is expected that an address of welcome will be given by the President of the United States and the retiring president of the Association, Dr. A. A. Michelson, will give his annual address, the subject being "Recent Progress in Spectroscopic Methods." The various sectional meetings begin at 10 A. M., December 27th. The programme of entertainments includes an exhibition cavalry drill at Ft. Myer on the afternoon of December 28th, and an informal reception at the Corcoran Art Gallery the same evening.

The Australian Antarctic Expedition

DR. MAWSON'S projected antarctic expedition has secured a suitable vessel—the "Aurora," built at Dundee in 1876—and the preparations are proceeding rapidly. As we have previously stated the object of this expedition is the thorough exploration of a portion of Antarctica, rather than a dash for the pole. It is announced that an aeroplane forms part of the equipment.

The Scientific American-Gould Prize

A COPY of the rules governing the competition for the flying machine prize of $15,000 offered by Mr. Edwin Gould under the auspices of the SCIENTIFIC AMERICAN will be found in the current issue of the SCIENTIFIC AMERICAN SUPPLEMENT.

Phases of Science as Other Editors See Them

A New Method of Chemical Analysis

IN a lecture delivered before the Royal Institution in the spring of this year, and reported on in *Nature*, Prof. J. J. Thomson made a communication which will mark one of the chief scientific achievements of the year. Sir Joseph's connection with the corpuscular theory of matter and his heroic attacks upon the most fundamental problems of chemistry, such as are presented to us in the periodic table of the elements, is known to our readers. Until recently J. J. Thomson's theory of the atom, while representing with remarkable truthfulness certain of the chemical properties of matter, was still largely theory. The work reported on in the lecture referred to above may be said to represent the first and most important step toward the realization by experiment of some of the conjectures which flow from the hypotheses advanced by the great physicist some years ago. The experimental arrangement followed is to project positive rays through a vacuum tube containing traces of the materials under examination, and to subject the rays to the influence of a magnetic and electrical field, disposed at right angles to one another. Under these circumstances, the rays is deflected and from the nature of the deflection it is possible to determine the mass of the molecules or atoms within the tube. The course of the ray is recorded photographically, and if several substances are present, a number of separate curves are obtained, forming a "positive ray spectrum." Our first illustration shows the spectrum of nitrogen prepared from air. Measurements on this photograph show that the atomic weights of the carriers producing the spectrum curves were as follows:

Positive	Negative
1·00 $H+$	1·00 $H-$
1·99 H_2+	11·20 C
6·80 $N++$	15·20 $O-$
11·40 $C+$	
13·95 $N+$	
28·10 N_2+	
39·00 $Arg+$	
100·00 $Hg++$	
198·00 $Hg+$	

The symbol $H+$ denotes that the carrier is an atom of hydrogen with one charge, H_2+ that it is a molecule of hydrogen with one charge, $N++$ that it is an atom of nitrogen with two charges and so on. A case of the highest interest is the positive ray spectrum of marsh gas (Fig. 2). The remarkable feature in this is that it discloses the presence, not only of marsh gas, CH_4, but also of substances having molecular weights, 12, 13, 14, 15, thus corresponding to bodies C, CH, CH_2, CH_3. With regard to these Sir Joseph remarks: "If I am not mistaken, this is the first occasion when the atoms CH, CH_2, CH_3 have been observed in the free state." The significance of this discovery to chemistry can hardly be over-estimated.

Schonbein remarked years ago—though the same words have held true until practically the present day—Shakespeare says that there are more things in heaven and earth than are dreamed of in philosophy.' Thus, presumably, intermediate between the state in which two portions of matter exist after completion of chemical combination and the state in which they previously existed separately, there is a series of transition states of which the chemistry of to-day knows nothing." It appears that now Sir J. J. Thomson has given us the key that opens the entrance to this realm of natural phenomena which, until now, has been practically a sealed book to us.

An Important Step in the Problem of Television

THE *electro-telescope* or "electric eye," invented by Prof. Rosing of the St. Petersburg Technological Institute, is said by Prof. Ernest Ruhmer himself a diligent and successful worker in this field, to mark an important step toward the practical solution of the problem of television. Prof. Rosing's ingenious apparatus, which has already been mentioned in the SCIENTIFIC AMERICAN SUPPLEMENT of June 17th, 1911, is described as follows by Prof. Ruhmer in a recent issue of *Die Umschau*:

The transmitting apparatus (Fig. 1.) is connected with the receiving apparatus at the distant station (Fig. 2) by six wires. Instead of the selenium cell used in most systems for transmitting gradations of

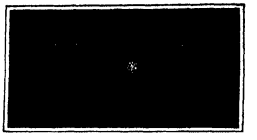

Fig. 1.—Positive ray spectrum of nitrogen.

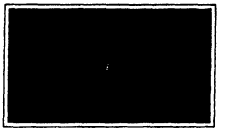

Fig. 2.—Positive ray spectrum of marsh gas.

light and shade, Prof. Rosing employs a photo-electric cell, which reacts much more quickly. This photo-electric cell F (Fig. 1) consists essentially of a glass globe, filled with rarefied hydrogen or helium and with its lower hemisphere coated internally with an amalgam of sodium or potassium, which is connected with the negative pole of a galvanic battery, the positive pole of which is connected with a platinum electrode which is fused through the glass at the top of the globe. In these conditions no current passes long as the globe remains in darkness. If, however, the amalgam which forms the cathode is illuminated, the rarefied gas is traversed by a current, the strength of which has been found by Righi and Stoletow to be directly proportional to the intensity of illumination and to follow exactly every variation of the latter.

In Prof. Rosing's transmitting apparatus (Fig. 1), an image of the object or picture MN is thrown by the lens L and the two polyhedral mirrors A and B, upon an opaque screen having a small aperture a, which is placed in front of the photo-electric cell F. The mirrors A and B rotate on mutually perpendicular axes with different velocities. The image is displaced in the plane of the drawing by the mirror B and in a direction perpendicular to that plane by the mirror A. By the combined action of the two mirrors the image is moved across the opaque screen in a series of parallel paths, so that every part of the image falls successively on the aperture a and illuminates the photo-electric cell F within a small fraction of a second.

The picture is reproduced at the receiving station by means of a Braun's tube. This device is an evacuated glass tube (R, Fig. 2) containing two electrodes, A, K, which are connected with the poles of an induction machine or other source of electricity of high potential. The cathode K emits cathode rays which fall upon a diaphragm through which a small pencil of the rays passes to a screen P. This screen is coated with potassium tungstate which is excited to fluorescence by the impact of cathode rays, so that a small luminous spot is formed at the point where the pencil of rays strikes the screen. Cathode rays can be deviated by electrostatic and by magnetic force, and Rosing makes use of both agencies. The Braun's tube is surrounded by two pairs of electromagnets, s t. One pair of electromagnets deviates the pencil of cathode rays in the plane of the drawing, the other in the perpendicular direction. Each of the mirror-drums A and B at the transmitting station (Fig. 1) carries a number of magnets which, as the drums revolve, generate electric currents in fixed coils, p p' p'' and q q' q'', near which they pass. Each of these two groups of generating coils is connected by two line wires with one pair of the electromagnets which deflect the pencil of cathode rays at the receiving station. In each case the current, the magnetic field which it produces, and the deflection of the rays are proportional to the angular displacement of the mirror-drum, which also determines the position of the reflected image at the transmitting station. The pencil of cathode rays, therefore, moves over the fluorescent screen in exact accordance with the movement of the image. The brightness of the fluorescent spot which thus reproduces the image at the receiving station is regulated by the condenser plates C C (Fig. 2) which are placed inside the Braun's tube and connected, respectively, through two line wires, with the positive pole of the battery at the transmitting station and with the platinum electrode of the photo-electric cell F (Fig. 1), while the negative pole of the battery is connected directly with the amalgam coating of the cell.

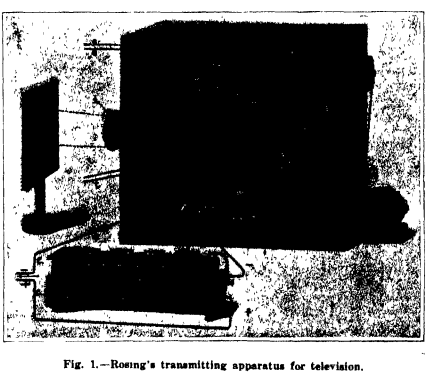

Fig. 1.—Rosing's transmitting apparatus for television.

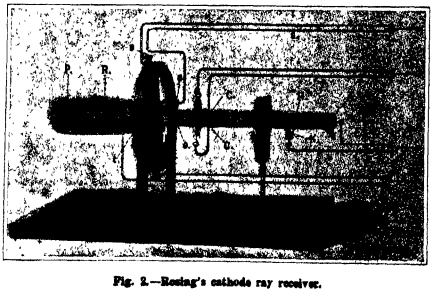

Fig. 2.—Rosing's cathode ray receiver.

In these conditions the strength of the electrostatic field between the condenser plates is proportional to the intensity with which the photo-electric cell is illuminated. The pencil of cathode rays which passes between the plates is correspondingly deflected so that a larger or smaller part of it is enabled to pass through a second diaphragm (o, Fig. 2) which is interposed between the condenser and the fluorescent screen, the diaphragms being so placed that no rays fall on the second one when the condenser carries no charge. Hence the brightness of the fluorescent spot which moves over the screen at the receiving station is always proportional to that of the corresponding point of the original image, and as the entire operation is repeated many times in a second, the fluorescent screen presents to the eye, in consequence of the persistence of retinal impressions, a motionless and exact monochromatic reproduction of the original picture.

Science

[illegible] Research in Spitsbergen.—A German research institution has been established in Spitsbergen, and Drs. Rampp and Wagner have begun a year's work there in aerology and geophysics. A unique interest attaches to the observations of the upper air that will be made throughout the polar night.

Aerial Post in Italy.—The latest country to try an aerial postal service is Italy. The Italian aeronaut Mistro recently carried a sack of mail between Bologna and Venice postoffices in a Deperdussin aeroplane, covering the distance of 101 miles in 1 hour and 28 minutes.

The Utilization of Grape Pips.—The utilization of by-products is one of the most striking characteristics of modern industry. A recent example is found in Italy, where a means has been discovered to turn to account the hitherto worthless pips of the grapes used in wine-making. Oil is now extracted from them on a commercial scale by a process of direct heating with tetrachloride of carbon. The latter is obtained in abundance in Italy in the preparation of electrolytic soda.

Nobel Prize Winners.—On December 10th, King Gustav of Sweden presented the Nobel Prizes, with the exception of the peace prize, to the winners. Mme. Marie Sklodowska Curie personally received the prize for chemistry, Prof. Wilhelm Wien of Wuerzburg University the prize for physics, and Prof. Allvar Gullstrand of Upsala University the prize for medicine. The Belgian Minister received the prize for literature in behalf of Maurice Materlinck, who was ill. The Nobel Prizes each amount to nearly $40,000.

Upper-air Research in Canada.—The Meteorological Service of Canada has been making observations of the upper air with sounding balloons since February last, and has achieved some excellent results. Of sixteen balloons sent up, eight have been recovered to the present writing. The altitudes attained have varied from 11.2 to 23.2 kilometers (about 7 to 14 miles). The isothermal layer was found at an average height of 13 kilometers (8.1 miles). The lowest temperature recorded was 70 deg. below zero Cent. (94 deg. below zero Fahr.) at an altitude of about 8.7 miles.

A Meteorological Tea.—In connection with the Washington meeting of the American Association for the Advancement of Science an informal gathering is to be held at the Weather Bureau, Thursday afternoon, December 28th, from 3 to 7, when "The Relation of Meteorology to Other Sciences" will be discussed, and the visitors will be given an opportunity of inspecting the installations and work of the bureau. Eminent representatives of several sciences have been invited to make brief addresses on the meteorological bearings of their several fields of work. The promoters of this undertaking hope that a similar *conversazione* or tea may become a permanent feature of the association's annual meetings, at which meteorology has not heretofore been represented in any definite way.

The Bend of the Brahmaputra.—We recently referred in these columns to the remarkable fact that the great bend of the Brahmaputra—where the river turns southward, in Tibet, and begins its course toward the Bay of Bengal—remains to this day a geographical question-mark for a distance of nearly a hundred miles. Probably no one bit of the earth's surface, with the exception of the poles, has been the object of such keen curiosity on the part of geographers. It is now reported that the British authorities in India are preparing a punitive expedition against the savage Abors—whose hostility has been the chief obstacle to the exploration of the region in question, and whose latest misdeed was the murder of Mr. Noel Williamson and Dr. Gregorson. In the course of this expedition it is almost certain that the unknown stretch of the river will be explored, and the identity of the Tibetan Tsangpo with the Brahmaputra will be fully established.

The Canton-Hong-kong Railway.—The American consul general at Hong Kong reports the formal opening on October 4th of the Canton-Hong-kong Railway. The British section, which was built by the colony of Hong-kong and opened about a year ago, extends from Hong-kong or Kowloon to Sam Chun, about 22 miles; it is tunneled through many mountains and cost $5,164,710. The Chinese section, built by the Chinese government with money lent by the colonial government of Hong Kong, extends 89 miles from Sam Chun to Canton, and cost $6,510,080. The freight cars were mostly imported from England, but the passenger cars were made in the shops of the Railway Administration of North China, except those of the British section, which were made in Hong-kong. Some of the rails are from Chinese works at Hankow. In fact, a noteworthy feature of this and other recently built railways in China is the large amount of the equipment that is Chinese-made.

Electricity

Meat Shrinkage in Electrical Cooking.—A recent consular report calls attention to the tests at the London Electrical Exposition which demonstrated that the shrinkage of meat when cooked in a coal range is somewhat greater than that of the same meat cooked in a gas range, and considerably more than when cooked in an electric range. A leg of mutton weighting 8 pounds and 8 ounces showed a shrinkage of 2 pounds and 11 ounces when cooked in the coal range, whereas a leg of mutton weighing 9 pounds showed a loss of 1 pound and 4 ounces when cooked in an electric oven. The shrinkage for the gas oven was 2 pounds and 4 ounces on an 8-pound leg of mutton.

Helium Tubes as Light Standards.—It was brought out at the meeting of the Philosophical Society of Washington last November that the Bureau of Standards has been experimenting with various gases, with a view to obtaining a vapor lamp which may be used as a light standard. The best gas was found to be helium. The light produced in the helium tube is a yellowish white, similar to that of the Hefner flame, and of carbon filament lamps. Other gases which seemed promising were dioxide and sulphur dioxide, but these were rejected, owing to the fact that the light they emitted was too white. The helium tube shown by experiment to be best adapted for the purpose was 7 centimeters long, with a bore of 2 millimeters and a wall 2 millimeters thick. The tube was provided with terminal bulbs 35 millimeters in diameter, containing aluminium electrodes 25 millimeters in diameter. With this form of tube the density of the gas did not affect the light over a range of 3 to 8 millimeters pressure, and a practically constant light was emitted, even though the voltage and the frequency of the current varied considerably.

Paris Suburban Railroad Electrification.—It will be remembered that a project is on foot for electrifying the whole of the Paris suburban railroad lines belonging to the West State system, and the expense of carrying this out is estimated at nearly $30,000,000. No definite decision has been made as to what electric method will be employed for running the trains. The plans left over from a former commission called for the use of a line somewhat resembling the Metropolitan subway, and the new commission is engaged in bringing these up to date. This method of looking at the subject is criticised, however, by outside engineers, as they claim that the suburban lines should not be operated on the same plan as the subway by direct current motors, but that such roads should be considered as part of the trunk lines and would be better run on the single-phase system, such as is adopted by the Prussian, Swiss and Swedish governments and elsewhere. The advantage would be felt when it comes to extending the suburban lines, as this can be done indefinitely, while it would be difficult on the present plan. Besides, there would be no need for substations placed along the road. As there are 130 miles of suburban track, this would require quite a number of such stations.

Around the Globe by Wireless.—A project is being developed in France by which it is expected to send wireless messages around the globe, and this will be done by erecting stations in the French colonies. A commission has already been formed by the colonial department to carry out the enterprise, and Commandant Ferrié, the well-known wireless engineer who is at the head of the Eiffel Tower plant is in charge of the technical matters. Not more than $2,500,000 will be required for the twelve wireless stations called for by the programme, and it should be completed in about two or three years. Messages sent out from the Eiffel Tower at Paris will first reach the posts erected at Dahomey and Timbuctoo in west Africa. Thence they will cross the continent to the coast of the Red Sea at Djibouti or else proceed southeast to Madagascar. Either of these two posts can then send messages across the Indian Ocean to the post in India at Pondichery, whence they will be transmitted to the eastern coast of Asia at Saigon. About 5,000 miles separate this point from the island of New Caledonia, to the north of Australia, and this can be covered by a high-power station. The Pacific will then be crossed by stations at Tahiti and the Marquise Islands. It then remains to cross over Central America so as to reach Martinique in the Atlantic, then crossing the ocean to the west African coast at Rufisque. From here the circuit around the globe will be completed to Paris. The main object of the French enterprise is to connect the capital with all the colonies spread over the earth's surface and also to connect all the colonies among themselves. This will give a great advantage over the present telegraphic cables, which frequently break and need repairs and are often owned by foreign companies. It is interesting to note that the waves sent from the Pacific to the Atlantic posts will cross over the region of the Panama Canal.

Aeronautics

Moving Pictures from an Aeroplane.—The photographer who accompanied Robert G. Fowler on his coast to coast trip for part of the way, has been taking motion pictures from Fowler's aeroplane. It is stated that a special apparatus was employed to overcome the vibration caused by the aeroplane engines. We are not informed whether the films are a success.

Vedrines' Falls.—On December 8th, Pierre Vedrines fell with his monoplane at Moranmes from a height of 75 feet. His collar bone and right arm were broken. This would not be so serious were it not for the fact that grave internal injuries were also sustained, with the result that some concern is expressed whether or not Vedrines will survive the accident. He had only just recovered from a very bad fall at Hericourt on September 13th, in which two of his ribs were broken. Vedrines is one of the crack flyers of France.

An Adverse Wright Decision.—The suit brought by the Wright Company against Claude Grahame-White for damages resulting from an alleged infringement of their patent has been decided in Mr. Grahame-White's favor by the United States Court, Judge Hand presiding. The judge said: "It is well settled by numerous authorities that the word 'damages' in the section includes profits. Therefore, under the complaint as it now stands the complainant cannot recover upon the accounting any damages or profits prior to the bringing of the suit. The question of costs is reserved for final action."

Final Award of the Statue of Liberty $10,000 Prize.—At a meeting of the International Aeronautic Federation in Rome last month Grahame-White was finally awarded the $10,000 prize for the race from Belmont Park to the Statue of Liberty and back, which was flown during the meet at Belmont Park a year ago. The two other competitors, the late John B. Moisant and Count de Lesseps, were each declared to be the winner of this prize at one time or another, but Grahame-White's protests that Moisant had not flown one hour continuously at the meet in accordance with the rules and that Count de Lesseps fouled a pylon were sustained.

The Aeronautic Shows in Paris and New York.—The Third International Exhibition of Aerial Locomotion opened in the Grand Palais in Paris on December 10th. The great advance made in aviation during the past year was apparent from the great number—about two score—of excellent aeroplanes on view in the main hall, as well as from the large number of makers of accessories who exhibited in the galleries. All told, about 350 makers of aeroplanes and accessories had their product on exhibition. With the exception of one Englishman and two Germans, all the exhibitors were French. Fifteen different makes of aviation motors were on view. Many lectures by men prominent in aeronautics will be given during the fortnight the exhibition is open. New York's first big aeronautic show is to be held next May under the auspices of the Aero Club of America.

An Aerial Taxicab.—Blériot has built for Henri Deutsch de la Meurthe a veritable aerial taxicab. The machine has a body which looks for all the world like that of a taxicab body. The passengers enter by a side door and view the landscape below through mica windows. Pneumatic cushions protect the passengers in rough landings. The pilot sits in front of the machine like a true chauffeur, and controls the machine with regular Blériot *clocks* and foot tiller. There is even a speaking tube to facilitate communication between the passengers within the taxi and the chauffeur. The elevator has been placed in front instead of in the rear. A 100-horse-power Gnome engine is mounted on top of the cab and with it the fuel tanks. The spread of wing is 43 feet from tip to tip, and the over-all length is 46 feet. Ready for flight, without passengers, the aeroplane weighs 1,540 pounds.

Recent Aeroplane Fatalities.—On December 2nd Tod Schriver, one of the first fliers to be taught by Curtiss, was killed by a fall at Ponce, Puerto Rico. He had been flying in a strong wind about 10 minutes and was descending in order to alight when he made a sharp turn and at the same time accidentally accelerated his motor. The result was that the biplane tipped still more and then slid sideways to the ground. It struck on one end in a cane field, and Schriver was so badly hurt that he expired soon after. The same day Lieut. Baron von Eteeting Lorinchoven fell and was killed at the Doberitz military aviation field in Germany, while on the 3rd last another German aviator, Herr Reeb, met with the same fate while flying across country from Munich to Nuremberg. Three days later Hubert Oxley and his passenger Wobss fell to their deaths at Filey, England, while flying a powerful Blackburn monoplane. On December 13th Lieut. Charles Lantheaume, a French military aviator, was killed by a fall at Melun just as he arrived after a successful flight from Etampes.

View in the sorting room of an artificial silk factory.

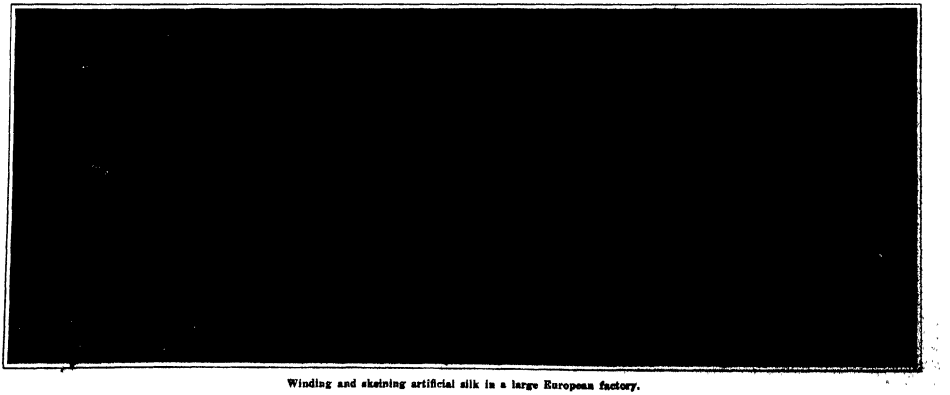
Artificial Silk—A Textile Marvel

Making Lustrous Yarn from Wood Pulp

By H. W. Ambruster

"YOU can not make a silk purse out of a sow's ear" is a familiar quotation. Its use, however, will probably be discontinued by the next generation, as silk is now made artificially by mechanical means out of material which, if not a product of the pork packer's slaughter house, is about as low down in the aesthetic scale. Wood pulp—made from spruce trees, or in fact from any variety of wood—is dissolved in various chemicals and the solution is spun into a beautiful lustrous yarn, the sheen and gloss of which outrivals the most costly cocoon silk. An industry of enormous proportions has been built up with the development of this new product, factories in Austria, France, Germany, and more recently in England turning out many thousands of pounds of the yarn every day.

And at the present time an enormous plant is just starting to manufacture in this country (near Chester, Pa.) making the same product. In certain textile lines, notably the braids and trimmings for women's dresses and hats and in knitted neckties, the artificial silk or wood silk as it is sometimes called has practically replaced the real article. Probably ninety per cent of the braids and passementerie now manufactured are wood silk, though the retail consumer seldom realizes this fact. The yarn is also used largely in tapestries and curtains and dress goods, while ribbons and various other fabrics supply an almost limitless field which is being invaded by this latest triumph of man's ingenuity. True synthetic silk has been made by chemists, it is claimed, the product of the cocoon being absolutely duplicated in every respect, chemical and physical, but this achievement, successful as it was as a scientific laboratory experiment, had no commercial value on account of the enormous cost of production.



A, B, D, are made entirely of artificial silk. C is a dress fabric made of worsted and artificial silk.

On the right is shown some raw cotton seed fiber; on the left, pure cellulose made therefrom; in the center, some spruce pulp.

A Frenchman, Hilaire de Chardonnet by name, was the first to make wood silk on a commercial basis, and although he is now very wealthy, it is said that he went into bankruptcy several times before he was finally successful. Chardonnet used a solution of nitro-cellulose in which sulphuric ether is the solvent, and several of the largest of the European mills are still using his process or modifications of it. The second process to be developed commercially was based on the use of what is known as the cuprammonium solution of cellulose in which copper salts and ammonia are the solvents. A third cellulose solution was discovered about twenty years ago by the English chemists, Cross and Bevan, and "viscose," as it is called, is now rated as the best of them all for making the artificial filaments.

The nitro-cellulose process depends on the use of the same solution that is used for making celluloid and guncotton and the first yarn made from it was highly explosive and dangerous to handle being therefore impracticable as a commercial article. After numerous failures, however, the French inventor discovered a way of denitrating the finished yarn and thus made it no more explosive or inflammable than so much cotton or paper. A German chemist by the name of Lehner made further improvements in the Chardonnet process and now there are great factories at Besançon in France, at Frankfort, Germany, and Zurich, Switzerland, where thousands of pounds of Chardonnet silk are manufactured daily. The nitro

Winding and skeining artificial silk in a large European factory.

MAKING SILK FROM WOOD PULP

...loose solution, made by dissolving the wood pulp in ...r, is squirted through exceedingly fine jets or ...illary tubes of glass. As it emerges either into a ...ter bath or into the air the cellulose originally held ...solution partially solidifies and a gummy filament ...the result. A number of these filaments, 12 to 20, ...e gathered together and twisted into a yarn in the ...me way that cocoon silk threads are spun or thrown ...gether. The artificial silk threads, while still soft ...d gummy are then stretched on drums or reels and ...ried, during which process they take on the beautiful ...ster so eagerly sought for by silk manufacturers.

The process of making viscose silk starts from an ...lkaline solution of cellulose. The wood or cotton ...lp is treated with caustic soda until a mercerization somewhat similar to the chemical reaction in ...mercerising cotton yarn has taken place. But the decomposition is carried much farther in making viscose. Bisulphide of carbon is then added to the partially decomposed pulp and the fibrous nature of the ...aterial disappears, altogether leaving a gummy mass which passes into a perfect solution when weak caustic liquor is added. For spinning the viscose solution somewhat different apparatus has been developed from that used for the earlier processes

All mechanical impurities, etc., are removed from the viscose solution by filtering the same through cotton wadding and cheese cloth. The clear solution then passes to a small platinum cap in which are drilled 15 or 18 holes approximately 4/1000 inch in diameter. The cap is immersed in an acid bath and the alkali in the viscose as it emerges from the spinneret is neutralised by the acid, the particles of cellulose coming together into 15 or 18 filaments according to the number of holes in the cap. Instead of being wound upon a reel at this point these delicate threads are dropped over a bobbin or pulley wheel into a small hole in the top of a rapidly revolving spinning box This box turns at some 1,500 revolutions per minute, and the centrifugal force throws the filaments away from the center and winds them up in a cake, also putting a slight twist into the resultant yarn. The yarn is then reeled into bundles or skeins on a regular silk winder, being drawn from the inside of the cake.

The advantage of this method of spinning the soluble cellulose, as compared with former methods in which the filaments were reeled into skeins as soon as spun, is the delicacy of the apparatus. The filaments, until they have been stretched and dried, are exceedingly frail and the less they are handled, the more perfect the yarn produced.

All of the artificial silks take the same dyestuffs as cotton and are readily dyed, the luster being brilliantly accentrated especially by certain shades Care has to be taken, however, while the skeins are wet as the filaments loose much of their strength while in this condition The cellulose is very hygroscopic and after absorbing a large percentage of water, swells up and its physical structure is much weakened But as soon as the yarn dries again it is as strong as ever, and the luster returns with all of its original brilliancy The appended table, prepared by Haller, a French expert, shows some interesting figures obtained as the result of strength tests with various samples.

All the forms of soluble cellulose are progressive solutions, the chemical reaction being continuous, and great care has to be taken to spin the mixtures at exactly the right moment to get the best results In consequence, a fixed temperature is necessary for all rooms in which the solutions are mixed and aged

The artificial silk filaments when dry are of almost incredible fineness, one pound of yarn of some sizes containing as many as six hundred miles of individual filaments The bulk of the yarn spun contains about 33,000 yards to the pound, 18 filaments being twisted together to form the yarn A conservative estimate of the total length of the filaments produced daily at the present time by the world's factories is considerably over 3,000,000 miles every 24 hours

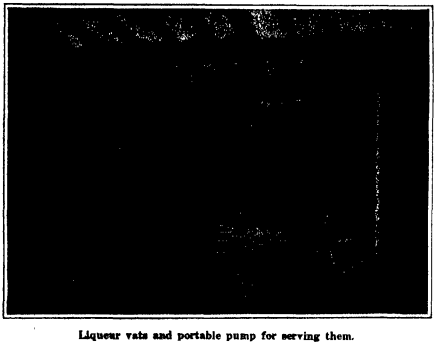
Cotton pulp is used instead of wood pulp in some of the foreign artificial silk factories and has been experimented with extensively in the United States, but wood pulp seems to be considered more suitable At the present time about 20 per cent of the world's consumption of silk yarn is the artificial product

Many millions in money have been expended in Europe and America in the perfection of the various processes for spinning artificial silk, and as is usual in the development of a new industry, the inventors and original pioneers as a rule have reaped but a small share of the profits The first American group to exploit viscose expended over $1,000,000 in experimenting, without obtaining any return whatever

		Absolute Strength in Kilogrammes per Millimeter of Diameter	
		Dry Thread	Wet Thread
Cotton, ordinary thread		11 5	18 6
Cocoon or Real Silk raw (in the gum)		50 4	40 9
" " "	boiled off (gum removed)	25.5	13 6
" " "	dyed black and weighted to 111 per cent	12 0	8 0
Artificial Silk	French Nitrocellulose Chardonnet	14 7	1 7
"	German - Nitrocellulose-Lehner	17 1	4 3
"	French - Cupra-ammonium-Pauly	19 1	3 2
"	English-Viscose-Steam	21 5	4 5

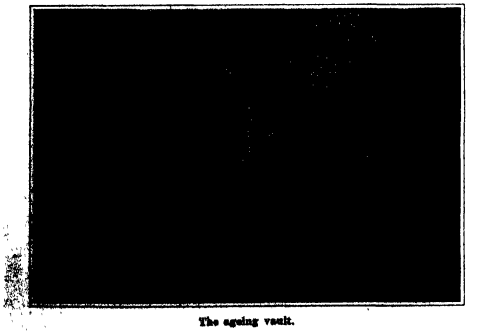
In another generation, however, the manufacture of artificial silk will probably be standardized, and as well understood as the wool and cotton industry of to-day

The World's Oldest Liqueur Distillery



A Monastic Plant Dating Back to 1084 A.D.

THE world's oldest distillery well deserves its title, for it has been making the liqueur known as Chartreuse since the jolly Saint Bruno dedicated La Grande Chartreuse to the manufacture of this historic cordial in 1084. For hundreds of years, Chartreuse has issued from this monastic plant, designed as a monastery, and built like one, with its iron-barred windows



In the great building constructed for the monks not employed in the distillery, the cells were lighted only by iron-grated doors and the inmates here lived year after year without seeing the sun, receiving their food through the opening in the grated door and spending the hours in prayer, reading and work No one, outside of the monks working in the distillery, was allowed within its doors and the priestly workmen themselves did not know how the liqueur was made.

The first to discover the secret of making chartreuse from the rare herbs that are found in the Dauphine Alps which separate France from Switzerland was Bruno How he learned it is not known Some of the French mountaineers may have had crude liqueur stills, but history has no record of the fact Bruno kept the recipe to himself and mixed the aromatic herbs in the right proportions. In a vault where not even the monks could see him He alone knew the exact temperature to maintain in the steeping vats, and the different lengths of time needed to extract the essences from the various herbs The mixing of the liquids was also done exclusively by the saint None but he could gage the exact proportions to make the perfect blend When age caused Bruno to give up his duties, his successor was obliged to take an oath that he would tell no one of the secret processes, and that he would perform Bruno's work until compelled to give it up; when he would hand down the re-

Panoramic view of the "Maine" and the inclosing cofferdam. To the extreme left is the bow, broken off and thrown astern. The boiler marks the region of the explosion. To the right of this is the after portion of the ship, which is practically intact

The bow, torn entirely away from the hull, was thrown around to starboard. The stem lies at right angles to the keel and in a horizontal position

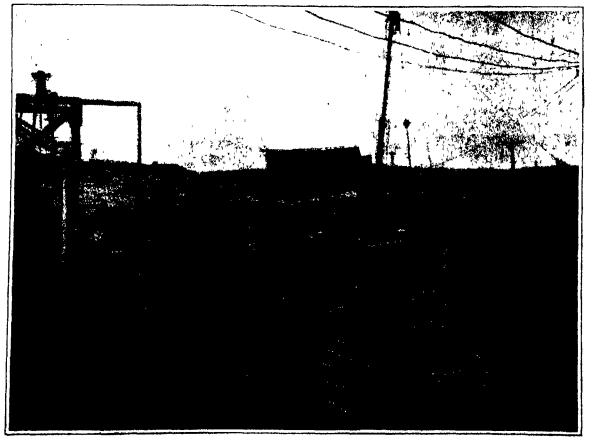
Destruction of the "Maine" by a Low-explosive Mine and Her Own Magazines

THE Engineer Corps of the United States Army is to be congratulated upon having brought to a successful conclusion a difficult and unique work of marine cofferdam construction and excavation which in this particular class of work, is without parallel in the history of engineering. We refer to the successful unwatering of the sunken battleship "Maine." Sunken vessels have been recovered in various ways, but never, so far as we know, has a ship lying on the bottom been salved from the water by the method adopted in the case in question. The recovery of a ship of six or seven thousand tons displacement, lying in 47 feet of water upon a bed of mud and soft clay of approximately equal depth, is a problem of considerable magnitude, even when the hull of the ship is in an approximately sound condition; but when, as in the case of the "Maine," the forward third of the vessel has been blown entirely to pieces, the difficulty is many times multiplied. When the army engineers received instructions to recover the 'Maine' so that every part of the ship could be subjected to a thorough examination, they were confronted with a problem which they might well have pronounced impossible of solution.

The plan adopted of building entirely around the wreck a massive cofferdam wall extending from solid bottom to several feet above high water mark, was the subject of much criticism from the day the plans were first made public. Complete failure of the cofferdam was freely predicted by the engineering profession. Yet in spite of the difficulties due to the tendency of the mud-filled wall to leak and to yield by distortion, the fact remains that it has done its work, and that the army engineers have so far laid bare the wreck that not only will the after two-thirds of the ship be floated and towed away to be sunk at sea, but practically every part of the wrecked portion of the structure has been made to yield its quota of evidence in determining the first cause of the disaster.

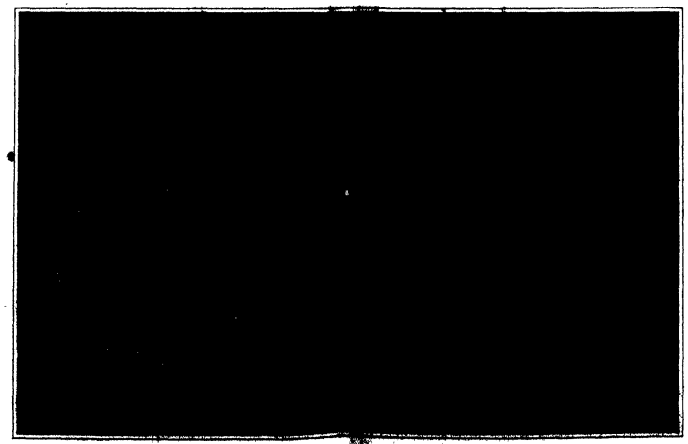
The joint army and navy board appointed by the Secretary of the Navy has presented its report, and an advance official statement has been given out at Washington which says, "The board finds that the injuries to the bottom of the "Maine" were caused by the explosion of a charge of a low form of explosive exterior to the ship between frames Nos. 28 and 30, strake B, port side. This resulted in igniting and exploding the contents of the 6-inch reserve magazine, A-14 M, said contents including a large quantity of black powder. The more or less complete explosion of the contents of the remaining forward magazine followed. The magazine explosions resulted in the destruction of the vessel."

The investigation disclosed the fact that there is a fracture some 20 feet wide extending across the bottom of the vessel at a point about 100 feet from the bow. From the fact that the frames were still in position, though, of course, much distorted, the board concluded that a low form of explosive was used in destroying the vessel. A high explosive would have caused a much more complete destruction of the material in its immediate vicinity. Incidentally, the report sustains the findings of the Sampson board, which investigated the disaster in 1898, immediately after the "Maine" was blown up. That board located the point of the exterior explosion at about frame 18 on the port side, but its report was based upon an examination by divers working in 37 feet of water. The unwatering of the "Maine" has made possible a closer approximation to the truth and it is now disclosed that the point at which the vessel was ruptured lies between frames 28 and 31.



The after portion of the hull remains practically in place. Forward of frame 30 is a gap of about 20 feet, where the ship was cut in two, and forward of the confused wreckage lies the bow, which was blown entirely out of position, swung around to starboard, and broken off from the ship's structure at frame 14. The stem of the vessel, instead of being in the vertical position, now lies horizontally and at right angles to the keel of the vessel, a considerable section of the plating on the port side being still attached to the stem. A long strip of the double bottom lies on the top of the after edge of the severed bow, and beneath this second portion rests a section of the keel some ten feet in length. One end of it lies in the mud, and the other end, twisted backward and upward, is now resting against the shell of the detached section of double bottom. In places the keel has been turned entirely upside down, so that some sections of the bottom plating are uppermost.

The sequence of events on the night of the disaster is now clear. A charge of low explosive, probably a large quantity, was set off below the bottom of the "Maine," forward of frame No. 30 on the port side, and a few feet from the keel. How this destructive agent was contained, at what depth it was located, and how it was set off, will probably never be known. Whether the mine was touching the ship or on the harbor bottom, the force of the explosion would seek the line of least resistance, which would lie vertically through the body of the ship. The rush of gases tore through the double bottom and the shock and heat of the explosion set off the black powder of which there was a considerable amount in the magazine just above the point of explosion, and this, in turn, ignited the forward magazines. The enormous energy thus liberated, having the water below and on the sides of the hull as an abutment, expended its energy in tearing asunder and folding back the overlying protective and other decks of the ship.



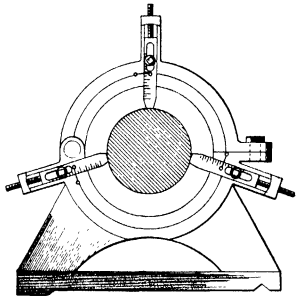
The illustrations which were published showing the recent wreck of the French battleship "Liberté" were strongly suggestive of similar illustrations of the wreck of the "Maine," published shortly after the event. The whole structure of the "Liberté" in the region of the explosion was opened out and folded back by the explosion of the magazines, presenting an appearance remarkably like that of the disaster in Havana Harbor. In the case of the "Maine" the magazines were set off by an exterior explosion, whereas on the "Liberté" the explosion was due to the deterioration and spontaneous ignition of the smokeless powder. It should be noted that outside of a comparatively small amount of ammunition for small arms, there was no smokeless powder on board the "Maine" at the time of the disaster.

View from amidships, looking toward bow, the wreckage of which is seen beyond the staging. To the right, in foreground, is one of the boilers; in the center is a portion of the keel.

Quarter deck and officers' quarters. Note the heavy timbers bracing the walls of cofferdam from the hull of the ship.

One of the 4-pounder tubes as recovered when the mud had been shoveled away. At this spot will be found the remains of Lieut. Merritt.

Looking aft into the body of the ship. In the foreground are the boilers. Aft is the timber bulkhead to be used in floating the hull.



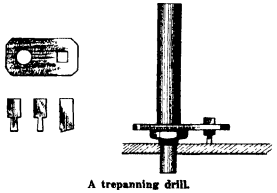
Suggestions for the Workshop

Ingenious Expedients of Resourceful Mechanics

A Steady Rest Kink

By H D. Chapman

IT is a bothersome task to change the steady rest jaws to accommodate different sizes of work. The following method was used to advantage. The steady rest was placed in position on the lathe and a line was scribed around the face of the rest as shown at *A*. The jaws of the steady rest were then



Steady rest with graduated jaws.

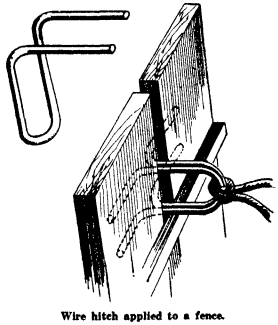
graduated in sixteenths of an inch on both sides of a zero line, as shown. The jaws were then placed in the steady rest and locked with the set screws after being set on the zero line. The jaws were then bored out while in position, thus making the graduation true.

Trepanning Drill

By Grover McKee

WHEN cutting out a hole in metal it is not necessary always to cut out all the metal in the form of chips and shavings. The most economical method is to cut out a piece of a desired diameter after the fashion of a surgeon when trepanning a skull. The accompanying illustration shows a method of doing this work. The drill consists of a shank provided with a reduced threaded portion and with a still further reduced projection, serving as a pivot. The plate

A trepanning drill.



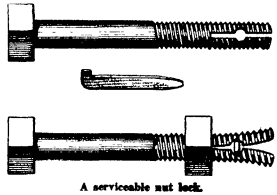
mounted on the shank is clamped in place by means of a nut which holds it securely against the shoulder of the shank. The plate is provided with a square aperture in which the tool is secured. The pivot of the drill is fitted into a small hole drilled in the center of the circle which is to be cut out. Then by driving the cutting tool into its socket and turning the shank, a circular slot will be made removing the metal in the form of a disk and leaving a hole of the desired diameter.

A Pocket Hitch

By Homer Cloukey

ILLUSTRATED in the accompanying drawing is a piece of stout wire about 8 inches long, shaped into a loop about an inch across with the free ends bent up at right angles to the plane of the loop. The drawing also shows the application of a pair of these bent wires to provide a hitch. They are slipped separately into a crack in a board fence and the tie rope or strap of a horse is attached. The girder of the fence will keep the strap from slipping to the ground and getting under the horse's feet.

This hitch may be applied to the side of a barn or any wooden wall if the owner carries a ¼-inch gimlet bit in his pocket with which to bore a couple of holes in the board. The chief advantage of this little appliance is that it can be carried in the coat pocket with convenience. It is also a feature that it can



Wire hitch applied to a fence.

be made with the bare hands. The one drawback is that it will not hold a genuine "puller" which would pull the wires through the crack, but for ninety-nine per cent of driving and riding horses it is a reliable hitch.

Novel Lock Nut

By G. H. Ander

AMONG many devices for preventing nuts from working loose there is one in common use consisting of a cotter pin which passes through a hole drilled in the bolt. However, this is not perfectly secure. The writer has found the following method better. It consists in slotting the end of the bolt, lengthwise, with a hack saw, and after the nut is screwed into place, driving a small wedge into the hole to spring the ends of the bolt enough to prevent the nut from turning. The wedge itself may be held in place

A serviceable nut lock.

by bending the pointed end slightly. When it is desired to remove the nut the wedge may be driven out, whereupon the nut may be unscrewed very readily. Sometimes bolts are riveted or center-punched in order to keep the nuts in their place. This, however, makes it difficult to remove the nuts and it requires that they be re-tapped. Furthermore, the bolts themselves must be run through a die before they may be used again.

Two Novel Reamers

By H. D. Chapman

IN the accompanying illustrations two types of reamers are shown which should prove very useful in the workshop. The form shown in Fig. 1 is known as a floating reamer, the cutting portion being connected to the shank by means of a knuckle joint. The writer recently had a number of gear wheels to bore to a finished size of 1⅝ inches. The hole was roughed out with a 1 7/64-inch drill, after which the floating reamer was used to bring the hole to size. The reamer shank is tapered to fit the tail stock, while the shank and the reamer are coupled together by means of a tapered pin indicated at *A*. This reamer was in constant use for ten days and gave excellent service.

The expanding reamer shown in Fig. 2 is notable for its simplicity of construction. Unlike the majority of expanding reamers, this reamer permits one to ream down to the bottom of a blind hole, as there are no projections beyond the front face. It has been found that

Fig. 1.—A floating reamer.

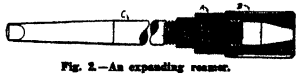


Fig. 2.—An expanding reamer.

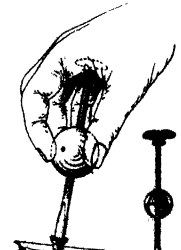
with machine reamers there is an advantage in having a slight clearance behind the cutting edges, hence the reamer illustrated herewith is provided with such clearance. The shank of the reamer is indicated by the letter *C*. It is provided with a taper of 30 degrees at the end. Upon this shank is a lock nut *A* which may be turned by means of a spanner wrench. The cutter proper is indicated at *B*. This also is provided with flats for a spanner wrench, and there are six saw cuts in it, so that it can be expanded. In adjusting this reamer it will be found that the front cutting edge is expanded slightly more than that at the rear, so that it is possible to obtain a clean parallel hole.

Rotary Marking Gage

By William Grotzinger

THE ordinary marking gage fitted with a pin to mark a piece of work is open to the objection that the pin is liable to follow the grain, especially in hard wood, giving an untrue line. The marking gage may be improved by substituting a steel disk roller for the pin. A small projection of wood may be secured to



A rotary marking gage.

the body of the gage and upon this a steel disk about three-quarters of an inch in diameter may be fastened with a small screw, permitting the disk to rotate easily upon the body of the screw. In use the disk will mark a true line regardless of the grain of the wood.

Improvement for Screwdrivers

PICTURED in the accompanying drawing is a very simple device which will be found useful on small screwdrivers. It consists of a swivel head secured to the upper end of the screwdriver and serving as a rest for the palm of the hand. The shank of the screw-

Screwdriver with swiveled palm rest.

driver is fitted with a handle in the shape of a ball, secured by means of a transverse pin. This may be turned readily by means of thumb and finger while the palm of the hand is resting upon the swivel head and holding the screwdriver firmly in place.

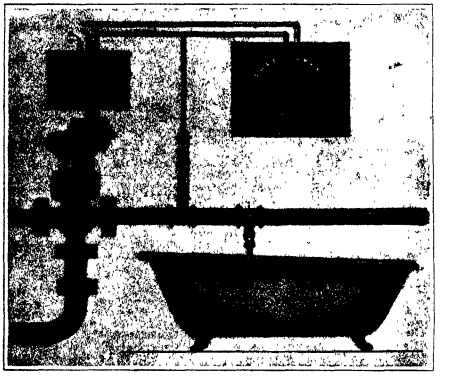
Automatic Mixing Valve for Bathing Water



By Frank C. Perkins

THE accompanying illustration shows a unique German electrically-operated mixing valve by which any desired warm water temperature may be kept constant. It is adapted for use in large institutions, such as baths, sanitariums, and the like, as well as for various industrial purposes where constant temperatures are required. It will be observed that the temperature is controlled by a thermometer whose bulb reaches into the pipe containing the mixed hot and cold water. This thermometer is provided with platinum contact points connected to a double-switch lever, which may be set for the maximum and minimum temperature desired. This double switch may be seen directly over the bath tub in our illustration. Wires run from the switch to a set of relays, shown at the left-hand side, which control the circuit of a motor that operates the mixing valve. This valve connects either the hot water pipe or the cold water pipe or both with the mixed water supply pipes. The operation of the device is as follows: If it be desired to keep the temperature within the limits of 78 degrees and 82 degrees Fahrenheit, the two switch levers are adjusted accordingly. Thereafter, the apparatus operates automatically. If the temperature in the pipe with which the thermometer connects is below the minimum, the circuit of the motor will close automatically, opening the valve to the hot water supply until the temperature of the mixture has been raised to or above 78 degrees. If the mixture grows warmer than 82 degrees more cold water will automatically be supplied. A large number of bath tubs may be supplied through a single mixing valve and the temperature of the water supplied to each tub will automatically be maintained between the predetermined limits.

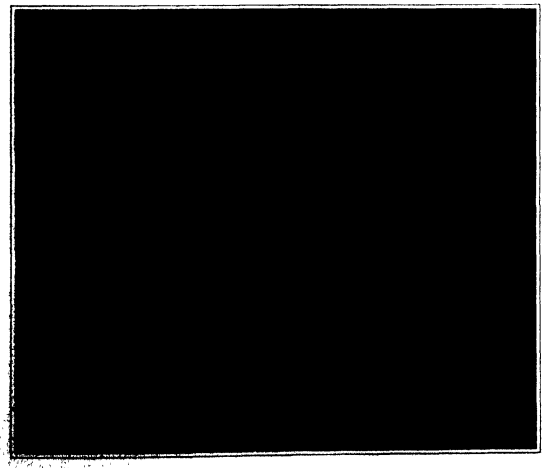
Removable Ambulance Linings

EVERY hospital for contagious diseases is now and then confronted with the serious problem of transporting persons without the loss of time necessary for proper disinfection of its ambulances. Many different patients, each suffering with a different disease, are received daily. Of course it is impossible to maintain a separate ambulance for each disease. A solution of the difficulty has been provided by the superintendent of a hospital in Buffalo. He has had five linings made which may be fitted into any of the hospital ambulances. One of these is used for scarlet fever cases only; another for diphtheria; another for measles; another for smallpox, and the fifth one for special suspected cases, or for other diseases not mentioned. These linings are stored in separate metal air-tight compartments built on a semi-circular platform at the edge of the garage turntable. The linings can either be disinfected in the ambulance, as all openings are made to shut tight, or they can be removed from the vehicle, placed on the ground and washed with soap and water. They may also be fumigated while in their storage compartments within the garage. Two men can exchange an infected lining for a clean one in five minutes. Thus a single ambulance is made the equivalent of five.

While this invention was originally designed for use by hospitals handling contagious diseases, it would no doubt be a benefit to the general hospital as well, because the latter is often called upon to transport patients supposed to be suffering with some simple malady, who, upon examination, prove victims of some dangerous and infectious disease. The advantage of using separate linings have been increased by the recent almost universal adoption of motor ambulances, which has rendered fumigation difficult, and washing almost impossible, because of wetting the electrical connections.

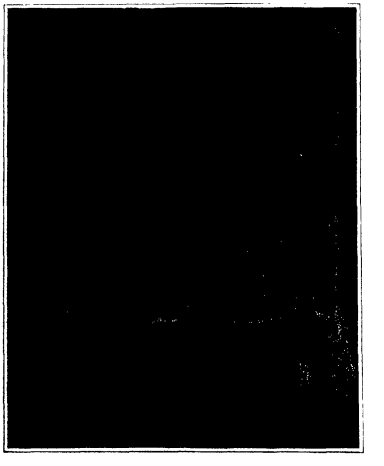
Automatic device for controlling the temperature of bathing water.

Particulars of the New Zealand Government's Offer of a Bonus of £12,000 (Nearly $60,000) in Connection With New Zealand Hemp



THE New Zealand Government has agreed to pay £12,000 (about $60,000) as a bonus or bonuses for improvements in connection with—

1. The extraction and dressing of fiber from the New Zealand hemp-plant (*Phormium tenax*), or
2. The utilization of the by-products obtained during the processes of extracting the fiber,



on condition that the machine or process in regard to which the whole or any part of the bonus is to be paid shall be recommended by the New Zealand Flaxmillers' Association, and approved by the Government.

The £12,000 will be paid, wholly or in part, for any of the following, viz:

1. A process of extracting and dressing the fiber of New Zealand hemp (*Phormium tenax*), whether by machinery or otherwise, whereby there shall be obtainable (*a*) a greatly improved quality of fiber marketable at a higher price, or (*b*) a substantial reduction in the cost of producing the fiber.
2. Any such process that shall produce a fiber fit for use in manufactures other than rope and twine spinning.
3. Any such process that shall render unnecessary any of the present operations involved in extracting and dressing the fiber, such as stripping, paddocking, or scutching.
4. Any improved method of separating the green envelope or the flinty or colored matter from the green leaf of the phormium plant so as to produce a strong white fiber the whole of which can be saved with little or no tow or waste.
5. Any means whereby the by-products obtained during the processes of extracting and dressing New Zealand hemp-fiber—such as the gum, dye, stripper-slips, tow-dust, or

The lining partly withdrawn.

End view showing the interior.

MOTOR AMBULANCE PROVIDED WITH REMOVABLE LININGS FOR CONTAGIOUS DISEASES

waste vegetable matter—shall be converted into a marketable commodity

Applications for the bonus must be addressed to the President of the New Zealand Flaxmillers' Association, Palmerston North, New Zealand, and must reach him not later than noon of November 30th, 1913 They must be inclosed in an envelope clearly marked "Application for bonus"

Each applicant shall state what lump sum (including the bonus of £12,000 or any part thereof) would be required to purchase the New Zealand rights of his machine or process in the event of such rights being acquired by the New Zealand Government for free use by the hemp-millers of the Dominion, or, if any applicant is unwilling to sell his rights, he shall state what *amount of bonus (not* exceeding £12,000) and what royalty he would require for the use of his machine or process

As soon as possible after the expiration of the time for receiving applications for the bonus (November 30th, 1913) the Flaxmillers' Association shall appoint a committee of not less than six of its members to open and examine the applications, to test such of the competing machines or processes as it considers worthy of trial, and to make recommendations to the Government as to the payment of the bonus

Each applicant must give, at his own expense, such reasonable demonstrations of the working of his machine or process as shall be demanded by the said committee, and such demonstrations shall take place in some convenient locality in New Zealand selected by the committee

The Committee shall notify the Secretary of the Department of Agriculture, Commerce, and Tourists at least fourteen days beforehand of the time and place appointed for such demonstrations, and shall allow any accredited representative of the Department to fully examine the working of the machines or processes that are being demonstrated

It should be noted that nothing in these conditions prevents a machine or process placed on the market prior to November 30th, 1913, from competing for the bonus

On completion of all the demonstrations it deems necessary, the committee shall consider the whole of the machines or processes submitted for competition for the bonus, and in doing so shall take the following matters in connection with each one into consideration

1 The amount of the lump sum or royalty required for the rights
2 The cost of purchasing, installing, and operating
3 The labor and time occupied in operating
4 The labor and time required after the operation and before the product is ready for packing
5 The cost of producing the fiber, tow, or other product
6 In the case of machines or processes for extracting and dressing the fiber, the percentage of fiber, and tow if any produced from a given weight of green leaves
7 In the case of machines, the simplicity, durability, and safety of the working parts

After considering the whole of the applications in the above respects, the committee shall forthwith submit to the Honorable Minister of Agriculture a report showing—

1 A complete list of all the applications received, giving the name and address of the applicant, the nature and purpose of the machine or process; the nature and value of the product, the quantity produced, the lump sum or royalty required for the rights, the estimated cost of purchasing, installing, and operating, the estimated labor and time occupied in operating, the estimated labor and time required after the operation and before the product is ready for packing, the estimated cost of producing the fiber, tow, or other product, the percentage of fiber, and tow, if any, from a given weight of green leaves, and, lastly, the simplicity, durability, and safety of the working parts
2. Whether they consider any machine or process worthy of the whole bonus, and, if so, which one.
3 If they do not consider any machine or process worthy of the whole bonus, then whether they consider any machines or processes entitled to a part thereof, and, if so, which ones and how much

For the information of persons who are interested in the above announcement, but who have little or no knowledge in regard to New Zealand hemp (or, as it is often called, New Zealand flax), it may be pointed out that *Phormium tenax* is entirely different from any other hemp or flax-plant The leaves from which the fiber has to be extracted are sword-shaped, and about four to nine feet long, they are moderately pliable, and of great tensile strength The fiber is embedded in tough vegetable matter containing a gum and a staining substance, and the greatest difficulty in the process of extraction is the removal of the vegetable refuse, gum, and dye without damaging or staining the fiber

Specimens of New Zealand hemp (*Phormium tenax*) can be seen in many botanical gardens all over the world

It would be of little use to send samples of the leaves outside New Zealand, as when cut they soon wither and become stiff and brown, and altogether useless for treatment by any known process.

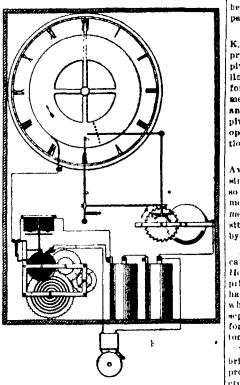
THOMAS MACKENZIE,
Minister of Agriculture
Department of Agriculture, Commerce, and Tourists,
Wellington, New Zealand, September 22nd, 1911

Notes for Inventors

A Change Making Machine.—This machine has holders for stacks of coins, and an electric motor which reciprocates a carriage to which fingers are pivoted for ejecting the lower coins from the stacks, pivoted plates lying normally in the paths of the fingers to prevent them from engaging their respective coins, electromagnetic mechanism being provided to shift any particular one of the pivoted plates out of the path of its corresponding finger to permit the last to eject a coin The patent, No 1,007,167, is to Everett A Wickline of Olympia, Wash

Baked Beans as a Hair Tonic.—We have always understood that, as a diet, pork and beans was "filling" but it remained for a California inventor, Thomas H Bartlett, to find out a few years ago, that it had the property of "filling" the hair into the head and to cause that already in place to "stick to" its support In his patent, No 920,002, Mr Bartlett describes his hair tonic as consisting of pork fat, bean oil and other specified ingredients, and describes with great particularity the cooking of a very nice edible dish of baked beans preparatory to completing the tonic Thus in the description forming part of his patent he says "I take three cups of common white beans and three pounds of salt pork The beans are par-boiled, and then boiled with the pork for eight hours, and then covered tight and baked for twelve hours" With brown bread that would make a pretty good Saturday night tea in Boston

An Umbrella Useful with Big Hats.—An umbrella that should be popular with the ladies wearing large hats is shown in a patent, No 1,008,456, to Leo C Barr, of York, Pa The stick or staff is in sections which include parallel links so arranged that while the handle portion of the staff may extend up in front of a big hat, the links will extend back over the hat so that the center of the canopy of the umbrella or parasol will be about over the center of the hat, although the parallel links may be adjusted into alinement with the rest of the staff.



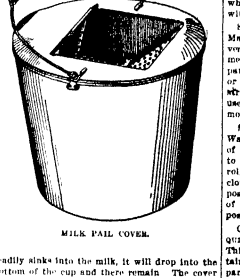
RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Electrical Devices.

SELF-SWITCHING ALARM.—B UHLMANN, 72 Plainderville Avenue, Garfield, N J This invention relates to burglar alarms for doors and the like, and its object is to provide a new and improved self-switching alarm, arranged to sound an alarm on retracting the key-controlled locking bolt of the door lock, and adopted to be normally held in a set position to permit of opening and closing the door, say during the day, without ringing the alarm

ELECTRICAL PROGRAM CLOCK.—GERTRUDE P. MILES, Sweet Home, Ore This invention relates to time-controlled electric alarms for periodically sounding alarms and its object is to provide a new program clock for use in schools, railroad stations, hotels and other places, and arranged to periodically sound alarms, to economize in battery power and to provide a mechanism of comparatively few



ELECTRICAL PROGRAM CLOCK

parts not liable easily to get out of order and not requiring delicate adjustment of the parts Use is made of an actuating and contact making member turning in unison with the minute hand of the clock and controlling periodically another contact making member for closing a circuit to sound an alarm The illustration is a face view of the clock

Of Interest to Farmers.

MILK PAIL COVER.—W R BUTNER, Topaz, Cal As soon as milk reaches the lowermost row of holes after a little has accumulated in the cup it is drained off from its upper surface and trickles through into the pail body, gradually filling the latter Any dirt in the cup cannot get into the pail being retained in the cup, as it cannot pass readily through the holes If the dirt happens to be of the kind which

MILK PAIL COVER.

readily sinks into the milk, it will drop into the bottom of the cup and there remain The cover can be disengaged and lifted gradually to different angles thus draining the milk out of the cup and leaving the dirt therein This requires but little practice The invention is shown herewith as applied to the pail The cover may be made of metal and of proper proportions to fit the standard pail

STEERING DEVICE FOR TRACTION ENGINES.—W D MILLER, care of Saco Mercantile Co., Saco, Mont In the present invention the improvement relates to traction engines and similar machines used for drawing gang plows over a field, and the object is to provide a new steering device for such machines, whereby the machine is automatically guided across the field in a straight line.

Hardware and Tools.

WRENCH.—C. G YOUNGQUIST and C. A YOUNGQUIST, 205½ Washington Street, Portland, Ore. This improvement pertains to wrenches, and it has for its object to provide one having an eccentric journaled to a movable jaw, with a worm mounted to rotate on the eccentric, so that by rotating the eccentric the worm may be moved into or out of engagement with the rack teeth on the shank of the teeth

SELF HEATING SOLDERING IRON.—A J WHITBECK, New Britain, Conn The object of this inventor is to provide a soldering iron having an improved construction and arrangement of the burner and means whereby the preliminary heating of the same is accomplished A number of heads of different sizes and shapes are provided and they may be used interchangably so that the tool may be instantly adapted to the character of the particular work to be done.

PIPE WRENCH.—W L. BESSOLO, P. O Box K, Spring Valley, Ill This invention comprises among other parts a handle and a jaw pivotally connected therewith to permit a limited oscillating movement of either, the former having a shoulder to limit its movement in relation to the latter in one direction, and a forward projection protruding above a pivot of the jaw to limit its movement in the opposite direction It is simple in construction, economical in cost and efficient in use

DIE HOLDER.—J. W CLARK, 707 Ashland Avenue, Muncie, Ind This invention provides a simple but powerful device for clamping a die, so that it will be held positively against movement in any direction, and wherein the holding *means may be firmly* locked in clamping position, without possibility of accidental release by any means.

ASH SIFTING SHOVEL.—C. F. HOFFMAN, care of Tuttle, McArthur & Dunnebacke, 501 *Hallitzer* Building, Lansing, Mich Among the principal objects which the present invention has in view are to provide an apparatus wherein the ash and partly burned coal are separated in the shovel; and to provide means for lifting the shifting device above the bottom of the shovel during sifting.

WRENCH.—F C BOTWRIGHT, 1825 Bainbridge Street, Philadelphia, Pa This improvement pertains to wrenches, and has reference more particularly to a device of this kind, comprising a pair of relatively movable jaws, means for actuating the same, and means whereby the jaws are released from engagement with an object between them when the wrench is turned in one direction

PNEUMATIC HAMMER.—V E LANE, 150 South Portland Avenue, Brooklyn, N Y Mr Lane's invention relates to pneumatic hammers, and has for its object to provide a detachable nose piece carrying the rivet set, or equivalent tool, and so arranged that the nose piece, when screwed on the barrel, carries with it the rivet set, while the last is in turn detachable from the nose piece independently of whether the latter be mounted upon the barrel or not

WIRE STRETCHER AND SPLICER.—M. W CORNETT, Miami, Texas. This invention is for use on fence wire or for tying wire around bales and the like Use is made of a handled winding shaft, having an eye and an arm, in which the winding shaft is mounted to turn, the arm having at its free end a hook for engagement with a loop on one end of a wire when splicing two wires, or for engagement with a fence post when stretching a wire

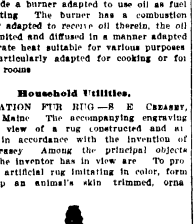
SAFETY RAZOR.—A ZILBERSHER, 1186 Madison Avenue, New York, N Y. The invention refers to a new and useful improvement in the art of safety razors and more particularly the invention involves a retainer or cap plate used on safety razors, the construction of which especially adapts it for use with blades which have been worn down more or less after honing or stropping

SHADE ROLLER.—C. K SNAVELY, 178 Washington Street, Bloomfield, N. J The aim of this inventor is to provide a roller arranged to insure an easy and smooth running of the roller for winding up and unwinding the shade cloth, to securely lock the roller in stopping position and to permit convenient assembling of the parts and securely holding the same in position

CURTAIN STRETCHER.—J O HOLMQUIST, 8318 Greenwood Terrace, Chicago, Ill. This invention relates to stretchers for curtains and analogous articles, and refers more particularly to a device of this class which comprises a frame including jointed bars, a brace member movably connected with these bars, and means whereby the bars, when extended, are constrained to assume positions at right angles with respect to the brace member

RABBI FASTENER.—I. G. FRENCH, 94 Winter Street, Orange, Mass. The object here is to provide a fastener which can be manufactured inexpensively from any suitable material, such as cast metal, which can be

stipulated without difficulty, by means of which the window sashes can be securely locked against accident or unauthorized opening, and which automatically locks when the window is closed



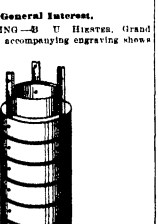
Heating and Lighting.

BURNER.—L M HASBROUCK, care of Continental Hotel, Broadway and 20th Street, New York, N. Y. An object of this invention is to provide a form of burner adapted more especially for use in an oil lamp, so constructed and arranged that cold air is supplied to not only the bottom part of the incandescent mantle, but is also supplied to the unburned carbonized gas at the upper portion of the mantle.

OIL BURNER.—W MC K. BURNS, 226 East 18th Street, Concordia, and R W BURNS, Cherryvale, Kan. The object in this case is to provide a burner adapted to use oil as fuel for heating. The burner has a combustion chamber adapted to receive oil therein, the oil being ignited and diffused in a manner adapted to generate heat suitable for various purposes. It is particularly adapted for cooking or for heating rooms

Household Utilities.

IMITATION FUR RUG.—S E CRESSEY, Alfred, Maine. The accompanying engraving gives a view of a rug constructed and arranged in accordance with the invention of Mr Cressey. Among the principal objects which the inventor has in view are: To provide an artificial rug imitating in color, form and nap an animal's skin trimmed, ornamented and arranged in simulation of rugs formed from natural skins, and to produce an article which is economical and durable. Where the rug is to be used as a floor piece and where further illusion is desired the head is mounted, a papier mâché or other suitable cranium being provided. This cranium is provided with teeth and eyes, as in rugs of ordinary constructions



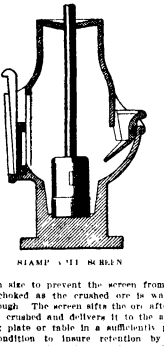
IMITATION FUR RUG

GAS LOG REST.—F S ALLEN, 517 West 134th Street, New York, N. Y. This improvement pertains to log rests used in fire places and the like, the more particular purpose being to provide a type of log rest suitable for use in connection with gaseous fuel and having a so-called "knock down" construction whereby the rest may be readily folded and unfolded for convenience in packing and shipping

SIPHON FLUSHING APPARATUS.—J I MEYER, 306 Lenox Avenue, New York, N. Y. The aim in this case is to provide a siphon flushing apparatus for flushing tanks, arranged to insure the emptying of the water of the tank from above the level of the water in the tank, and dispensing with submerged valves thus completely avoiding all leakage and waste

Of General Interest.

WELL CASING.—B U HIESTER, Grand Ridge, Ill. The accompanying engraving shows a perspective view of a number of units secured together in one manner. The invention relates generally to well casings, and more particularly it is directed to an improved means for holding together the units described and claimed in Letters Patent No. 1,001,523, granted to Mr Hiester. The aim of this inventor is to provide a means for securing in operative position a number of well casing units set forth in the above application, the said securing means being preferably vertically extending rods which may occupy a variety of positions with respect to the units



WELL CASING.

DISPLAY DEVICE.—W WELLER, Bonduel, Wis. This invention refers generally to devices which are adapted for use in displaying articles of furniture and more particularly it involves one especially intended to co-operate with the parts of a bed in order that the parts may be held in upright position and convenient for inspection

SHIP OR VESSEL.—G E ELIA, Hotel de Crillon, Place de la Concorde, Paris, France. This invention relates to ships or vessels and is particularly applicable for use in connection with vessels employed in naval warfare, the object being to preserve the stability of the same in the event of their being subjected to the effects of a submarine explosion.

METAL SPRING.—L. B DENIS, 185 Boulevard de Ménilmontant, Paris, France. In this invention the spring is formed from wire or metal rod of any convenient cross section bent on a flat or conical surface to form the outline of a conventional star, the radiating arms of which are subjected to torsional stresses when the exterior and interior supporting planes are moving together or apart

STAMP MILL SCREEN.—D C EN EAST ROLLINGVILLE, Calo. This invention consists of a screen to be used in the mortar of a stamp mill employed for the wet crushing of the ores of gold and other precious metals. The screen is shown in position in place on the mortar of the mill. The invention consists broadly in the number of bars arranged adjacent one another but spaced apart so as to provide openings therethrough, which openings gradually increase in size to prevent the screen from becoming choked as the crushed ore is washed therethrough. The screen sifts the ore after it has been crushed and delivers it to the amalgamating plate or table in a sufficiently powdered condition to insure retention by the quicksilver with which the plate is covered

STAMP MILL SCREEN

PROTRACTOR.—J GOODFELLOW, Cheever N H. This invention relates to a protractor of the type in which the various angles are designated on an arcuate periphery, whereby they may be transferred to any suitable work, and which is further provided with a supplementary arc or curve for determining various points and aiding in the solution of various geometrical problems

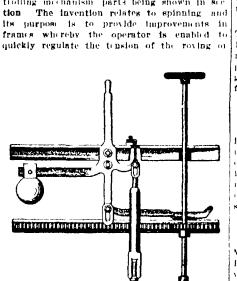
DAM.—J C WHERLON, Garland, Utah. The invention relates to hydraulic engineering, and its purpose is to provide a dam having a collapsible crest, which can be raised or lowered at will to permit flood waters to be safely discharged over the dam with the utmost safety to the dam and all the head works and controlling works connected with the waterway

GLUE MELTING PROCESS.—C M ZIMMERMAN, 221 West Third Street, Cincinnati, Ohio. In operation a converter is placed within the soaking tank and the glue put into the converter, and as much water afterward added as the glue can take up in passing into a jelly form. The vessel is then seated within the melting apparatus, where the glue is rapidly melted, and drips through the perforated bottom of the converter into the collector and thence runs out through the discharge pipes, thus soaking and melting are performed without transferring glue from one vessel to another

SAMPLE BOOK.—C. GREEN, 304 Canal Street, New York, N. Y. This invention relates to a sample book which is adapted to display textile fabric, wall paper or the like of various colors and qualities, both in their flat smooth condition and in a ruffled or rumpled condition, and in full yard length, so that *every* possible characteristic may be exhibited

FIRE EXTINGUISHER.—C H DRISCOLL, care of U. S. Smelting Co., Midvale, Utah. This extinguisher is arranged to utilize the tank containing the solution and the acid receptacle as a reel for the hose, the nozzle of which normally engages a lock for holding the reel against rotation, whereby the acid bottle is held suspended in the tank until the latter is unlocked or removal of the hose and the tank is rotated on unwinding the hose

DEPTH GAGE.—F J WALKER, Babylon, L. I., N. Y. In this gage the keepers are set back a substantial distance inward from the working edges of the head and the metal at these edges brought well to the blade so that the head gage will rest evenly substantially throughout on the surface, to which it is presented, and will not be raised therefrom when the head is laterally tilted



Machines and Mechanical Devices.

NEEDLE THREADER.—W J ROGERS, Box 567, 307 Madison Avenue, Plainfield, N. J. In this invention the improvement relates to needle threaders, and it has for its object to provide one having a handle with a guideway in which a member carrying a plunger is adapted to travel, a member carrying a thread catcher being pivoted to the handle, and having means for reciprocating the member carrying the plunger. Another object is to provide a spring arm adjustably mounted on the handle adapted to abut against the bottom of a needle bar for holding the plunger in alignment with the eye of a needle. The invention is shown in the engraving given the invention in position for service

NEEDLE THREADER

SLUBBING OR ROVING FRAME.—J D IRVING, 514 Edgmont Avenue, Chester, Pa. The engraving herewith shows a side elevation of a roving frame provided with auxiliary controlling mechanism parts being shown in section. The invention relates to spinning and its purpose is to provide improvements in frames whereby the operator is enabled to quickly regulate the tension of the roving on slubbing without knocking off and stopping the machine or without danger of injury to the hands. For this purpose use is made of an auxiliary tension regulating mechanism controlled by the operator and connected with the cross shaft, the mechanism extending to the front of the roller beam to be within convenient reach of the operator, to enable him to swing the shaft out or into gear

SLUBBING OR ROVING FRAME.

COPY HOLDER.—H URSCH, Little Falls, Minn. The object of the invention shown in the engraving is to provide a simple, economical and easily operated device which may be readily applied to and detached from a typewriter carriage, and which will travel with the carriage, will advance the copy synchronously with the advancement of the writing paper, and wherein the indicator of the type-writer carries the indicator of the copy holder, so that the two indicators always indicate on the copy that portion of the one that corresponds to the same portion of the other. The illustration represents the improvement in place on a typewriter

COPY HOLDER

Prime Movers and Their Accessories.

ROTARY ENGINE.—G T CUNNINGHAM, 1040 Margaret Street, Shreveport, La. The object of the improvement is to provide an engine wherein oppositely arranged blades are provided and wherein the motive fluid is permitted to act upon the blades during 180 degrees of their travel before exhausting, to gether with a simple and easily adjustable operating mechanism

CARBURETER.—M WERNOVA, care of Atlantic Yacht Club, Sea Gate, Coney Island, New York, N. Y. This invention has reference to certain improvements in carbureters for forming explosive mixtures and more particularly to that type of carbureter in which a liquid fuel is used and which is vaporized and mixed with air or other oxygen-bearing gas

CYLINDER AND WATER JACKET FOR INTERNAL COMBUSTION ENGINES.—J CRABB, West Union, Iowa. This invention provides a jacket constructed and arranged in such manner as to avoid breakage or other damage usually sustained by closed and rigid water jacket constructions caused by the expansion of the water contained therein when formed into ice, and provides a jacket to permit the rapid and easy separation of the same for repair or renewal

Railways and Their Accessories.

AUTOMATIC COUPLING.—H C NEWMAN, 1120 E Madison Street, Portland, Ore. This invention relates to couplers for train pipes of air brake systems, signal pipes, and steam pipes of railroad trains and refers more particularly to a device of this class comprising heads adapted to be arranged in juxtaposition to effect the operative connection of the pipes which are associated with the heads, one of the pipes associated with each head including a supporting means therefor, in combination with means controlled by the movement of the last-mentioned pipe, for operating the valves of the various pipes

MAIL CRANE.—F HANSEN, Woodbine, Iowa. This invention has reference to mail bag delivers and its object is the provision of a new and improved mail crane arranged to properly support the mail bag for normally engagement by the catcher with a view to unfailingly deliver the mail bag to the mail car

Pertaining to Recreation.

TOY GUN.—F A. KORP, Miami, Fla. This improvement relates to a gun which is made up of a frame member having a resilient band carried thereby, together with means for holding the band in stretched position and other means for releasing the band whereby the end of the band when released may be caused to strike some object, such as a fly or an insect

Pertaining to Vehicles.

COMBINED STEERING AND DRIVING MECHANISM.—S F SIGGERS and G A SIGGERS, Dolphus, Kan. This invention relates to motor vehicles and particularly to the means for driving and steering the front wheels of the vehicle. The object is to provide a motor vehicle with front steering wheels and with means for transmitting power to said wheels without interfering with their steering action. It provides a gearing for motor vehicle wheels, which will drive and shaft the same

RESILIENT METALLIC VEHICLE WHEEL.—W H WAITE, Jr., care of Atlantic Creosoting and Wood Preserving Co., Norfolk, Va. The purpose of this invention is to provide a vehicle wheel tire composed mainly of resilient metal, which is constructed having cooperative elements which are so combined that equal support and resilience under load strain are afforded for all parts of the wheel

WAGON.—T B MASON, 209 Warren Street, Trenton, N. J. This invention relates to wagons for carrying ashes, garbage or other refuse, and refers more particularly to a wagon comprising a body adapted to hold the material a movable material-receiving member having a normal position wherein it discharges into said body and forms a closure therefor, and means for operating the member.

Designs.

DESIGN FOR OPEN MESH FABRIC.—A. G JENNINGS, care of Jennings Lace Works, Park Avenue, Brooklyn, New York, N. Y. This ornamental design comprises open mesh work of pear-shaped design the rows of which alternate so that the points and heads of the pear shaped patterns are reversed. The design is original and the effect attractive. Mr Jennings has also designed an ornamental Face Veil with two border bands of slightly different widths, the bands slightly separated. The interior space comprises an ornamental field of lace-work of a beautiful pattern.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

The Technique of Clam Digging

IN our issue of December 16th, on page 564, we published a letter from Mr Hugh N. Johnson criticising our advertisement headed the "Technique of Clam Digging." The advertisement referred to appeared in the same issue on page 560 Our reply to Mr. Johnson's letter, which was inadvertently omitted last week, is as follows.

Your criticism of "The Technique of Clam Digging" is just—from the viewpoint of the Pacific Coast and some parts of the Atlantic Coast

The species of *Tapes* and *Saxidomus* which flourish on the Pacific coast, and the *Mya Arenaria*, which multiplies in long-armed softness on the north Atlantic coast, are harvested with a fork and bucket at low tide

Plainly the writer of the advertisement had in mind only the *Venus Mercenaria*, which, despite its suggestive name, is the aristocrat of the clam family, the only one having real gastronomic distinction It is true, the soft, long-fingered clam dug out of the mud appeals to many tastes when steamed and that it is also used sometimes for chowder, but it never ventures to raise its long, humble neck in the presence of its relative, the little neck

With the assumption of superiority familiar in the New Yorker—anybody who manages to exist in the metropolis for six months calls himself a New Yorker—the writer of the advertisement calmly took for granted that the only clam worth talking about is the lordly *Venus Mercenaria* In New York it is "the clam"—the long-necked variety being invariably designated as "the soft clam."

And the *Venus Mercenaria* or hard clam, or little neck, or quahog, is harvested exactly as described in the advertisement

The mistake the writer of the advertisement made was in assuming that this clam, more or less local to a small part of the seaboard, is the only clam He is a victim of insular prejudice rather than of ignorance —EDITOR

A Mechanical Evolution and Smokeless Cities

To the Editor of SCIENTIFIC AMERICAN.

No smoke on our rivers, no smoke on our lakes, no smoke from our factories, in fact smokeless cities, is the immediate boon in store for us through the most meritorious invention of the compressed-air internal-combustion engine* Before briefly explaining the principle of this beautifully simple motor, it may be well to give a short *résumé* of the development of the marine engine The oldest marine engine and boilers I ever had charge of were fitted in the steamer "Windermere" by John Penn & Sons of Greenwich in the year 1857 It was in this vessel that the first surface condenser, that most important of all adjuncts to the marine engine for salt-water service, was fitted by Samuel Hall The working pressure of steam was but 15 pounds per square inch, speed of piston slightly below 200 feet per minute, and the combined weight of engines, condenser, pumps, boilers and water therein equaled one gross ton for each indicated horse-power

Now the reduction of weight for power developed is the great desideratum for marine propulsion at least, and this is certainly true as regards propulsion in air The reduction of weight for a given power is most largely due to augmented piston speeds This speed has advanced during half a century from 200 feet to 1,000 feet a minute for reciprocating engines, and to 20,000 feet in rotary engines The other factors contributing to efficiency are higher steam pressures, greater vacuum, and stronger materials

Though the continuous development of the tri-compound and quadruple-expansion engines was inaugurated by the construction of the "Aberdeen," built in the year 1882 by R. Napier & Sons, the first triple-expansion engines were fitted in the "Propontis" by John Elder & Co., in 1874, their dimensions being 28 + 41 + 62 × 42 inches. The advancement of the triple or multiple expansion system solely through the failure of the Rowan boilers This, however, is no exception to the rule, the boilers have always been the troublesome and expensive element of marine propulsion, and their elimination will tend wonderfully to simplify the work and responsibility in the engine room

Fifty years ago the average consumption of fuel was about 5 pounds per indicated horse-power per hour. To-day this consumption is reduced to one-half pound of fuel per horse-power hour. The following table shows in chronological order over half a century.

The Reduction of Fuel Consumption per Horse-Power Hour.

	Fuel Consumption, Pounds
1850. Steam pressures 15 pounds	5
1860. Steam pressures 25 pounds with surface condensation	3
1870. Compound engines	2¼
1880. Triple-expansion	1⅝
1890 Quadruple-expansion (increased pressure)	1¼
1901 Internal-combustion engine	½

As it may appear somewhat remarkable, I may point out here that the consumption of crude oil fuel works out about the same, whether it be used explosively or to generate steam The space which could be saved for the accommodation of passengers and cargo in a 20-knot steamer by substituting the compressed-air, crude-oil, internal-combustion engines for the familiar steam engine or turbine installment, measures fully 5,000 cargo tons Now I venture to assert that the greatest mechanical invention since Samuel Hall invented the surface condenser, or probably since Watt devised the steam engine, is now afloat on our Great Lakes, and is being duplicated in that locality for coast service This is the Diesel improved internal-combustion motor or engine As this engine is beautifully simple and works with crude petroleum, of course without steam, it seems destined to quickly displace the steam turbine, and with it, the use of coal and steam, for propulsion at least, will no longer be required An engineer cannot witness the retirement of those good and faithful old servants without feelings of regret, especially since the advent, on a magnificent scale, of the steam turbine was so recent; still, it seems quite apparent that their day of usefulness is almost over. The adoption of the steam turbine was too long delayed to admit of a long lease of life, the principle of the De Laval impulse turbine having been clearly illustrated more than two thousand years ago. The internal-combustion engine of to-day does not weigh more than one-fifth of that of a marine engine and boilers of equal power, and when it is considered that there are gasoline engines on the market weighing not more than 2½ pounds a horse-power, who shall say that instead of being below one-fifth of the weight of the steam engine and boiler, the crude oil combustion motor may not be reduced to one-tenth or less of the weight of the steam boiler and engine instalment?

To me it appears that the sterling merit of this new invention is the beautifully simple means of firing the charge. Instead of the fickle and complicated electric spark system, the crude oil is ignited by a sudden and high degree of air compression within the cylinders. This device is not only reliable, but is very simple, which is of the utmost value for marine propulsion at least

Consider a steamer with large boilers, coal bunkers, coal chutes, coaling hatches, and all the paraphernalia for operating, cleaning, and repairing, and then try to imagine all of this weight and complication absolutely eliminated, and a space six times as large as the engine room thrown open for the stowage of cargo or the accommodation of passengers. Well, this is just what the adoption of the

*The invention of Dr. Diesel.

Practical Book With the Magazine That Makes Facts More Fascinating Than Fiction.

We offer your choice of the following practical books. Each one of them was written by an acknowledged authority in his special line. Its publication therefore is sponsored for their complete understanding. They are just the thing for the beginner, the practical man, or for that reading boy who is continually asking questions. They are not only for the worker or student in each special field, but for the intelligent reader who wants to know in a general way, how things are done in the trades and professions. Here is freedom.

Just Read These Titles

Automobiles	Electric Telegraph
Carpentry	Mechanical Drawing
Gas Engines and Producers	Power Boating
Masonry Construction	Pattern Making
Mechanical Drawing	Reinforced Concrete
Steam Engines	Steel Construction
Electric Railways	Surveying and Surveying
Bookkeeping	Architectural Drawing

BUSINESS BOOKS

Bank Bookkeeping	Department Store Accounts
Business Management, Part I	Factory Accounts
Business Management, Part II	Insurance and Real Estate Accounts
Corporation Accounts and the Voucher System	Partnership Accounts
	Practical Bookkeeping

Not all reprints or careless compilations, but new, up-to-date material, prepared especially for us.

Size of books is 6¾-in. x 9¾-in.; they are printed on a fine grade of high-calendered book paper, profusely illustrated with fine drawings and half-tones, durably and artistically bound in buckram and cloth. They are 6 to 8 books lodged from every standard of value in the publishing business. They sell regularly for $1.50 a first class book store. Some of them sell for $2.00.

Now Read What Technical World Magazine Stands For

TECHNICAL WORLD MAGAZINE believes that real achievement, real events, when properly presented, are far more interesting than mere fiction that the most thrilling story of adventure in the world is the story of man's conscious fight to conquer and overcome, and bend to his service the tremendous forces of nature. Its heroes are men of action, the men who, here World over, are really doing things, really encountering dangers, really coming out triumphant at the end of the story with a new achievement to be written large in the annals of our progress. These are the men that are more fascinating than fiction; the stories that you want to read—that everyone in your family wants to read; the things that you must know about in order to keep up to-date; the things that are really read about constantly in the pages of TECHNICAL WORLD MAGAZINE.

TECHNICAL WORLD MAGAZINE is not "technical," just wonderfully, interesting and fascinatingly interesting. You can read it, and you will read it, after TECHNICAL WORLD MAGAZINE just begins.

What Jack London Says:

"I have just chanced upon my first copy of TECHNICAL WORLD MAGAZINE There isn't anything like it I want more, and I cannot wait for them to come, so I am enclosing herewith check for $1.65 to cover entire year subscription and send me immediately the last two years' back numbers."

Read Our Big Offer

TECHNICAL WORLD'S subscription price is $1 50 per year, or 15 cents per copy on all newsstands. But any reader of this magazine may subscribe now and receive the next twelve numbers (an average of 1,000 pages) for $1 65 We want new readers, and at least many people who have never before heard of TECHNICAL WORLD'S pages to see the magazine, and come under its irresistible spell, as Jack London did, and they will become permanent readers, as he did also. So we make you this most unusual offer

Technical World Magazine For One Full Year (12 Wonderful Numbers) and Any Book Listed Above (Sent Prepaid)

All Only $1.65

After one book and the magazine have been ordered at $1 65, additional books may be added to your order at only 75 cents each, but half price. This is a splendid opportunity to get a full set of practical books. Read the titles over again and see how many there are that you ought to have.

Order at Once

Of course you know that this offer is urged to produce a perfect avalanche of orders. Of some of the books listed above, we have but 500 copies remaining. It will be best to order at once to avoid disappointment in not getting the book you want. Don't delay, for when the 500 are sold, that's all. Don't send stamps, for we don't want them, and don't send to us, with currency, stamps, silver or money order.

crude-oil motor will accomplish. Bearing this in mind, and with many concrete examples of this great transformation in evidence all the world over, I may venture to predict that no marine boilers and steam engines, for the propulsion of ships, at least, will be seen anywhere under construction, after the Panama canal has experienced five years' service.

Chicago, Ill. JOSEPH R. OLDHAM.

A Fatal Omission

To the Editor of SCIENTIFIC AMERICAN:

I want to compliment you on your editorial under the heading of "A Fatal Omission." I have no interest whatever in the Pennsylvania Railroad, but I do feel a most serious blunder has been made by New York city in not arranging subway connection with their new station I would like to see the press unitedly agitate the matter so that the convenience might be speedily brought about, and the general public receive a benefit that they are entitled to When we consider that ten million passengers were carried through the station the first year of its existence, it is a disgrace to the city that an immediate effort for relief is not put under way.

W. F. HARTRANFT.

Jersey City Heights, N. J.

The Current Supplement

THE front page article of the current issue, No 1877, of our SUPPLEMENT, is devoted to an illustrated description of the 3,000-horse-power Hydros Electric Power Plant at Cannon Falls, Minnesota —Prof. Wedgworth's article on the Psychology of Light reaches its second installment.—Frémont's new test for steel rails, which promises to become a standard method, is described —An article by P. V. Vernon deals with the influence of composition and previous history of steel on the power required to cut it —An article on "Developing a Small Water Power Plant" should prove of special interest to farmers and others located at a distance from city centers.—G. C. Sawyers, cheese expert, writes on the "Manufacture of Cheddar Cheese."—At the opening of the winter season an article on "Skis, Their Construction and Use," will be welcomed by many of our readers —A very scholarly account of "Wheels, Ancient and Modern," from the times of primitive man to the day of the steel-spoke automobile, is given by H L Heathcote —Condiments and Stimulants have their use, as well as abuse They are discussed from a scientific standpoint in an article derived from *Prometheus*

World's Oldest Liqueur Distillery

(Concluded from page 575.)

cipe to his successor, who would also be oath bound.

And so operations continued in the first monastery for nearly six centuries, when the order built another plant near Fourvoirie, the supply of raw material at the original location being exhausted The new plant was strictly ecclesiastical in architecture and cost nearly 5,000,000 francs—all paid out of income from the sale of chartreuse to the monastic orders in France, for until fifty years ago it was not drank by anyone except the French monks. It was regarded as a sacred beverage, and to sell it outside of the church was sacrilege. The mystery of chartreuse making and its peculiar taste were two of the reasons for its popularity, which was so great, once it had come into public use, that it was soon shipped, in kegs, all over Europe, to be bottled and sold by the bottle or glass in the cafés. When the Fourvoirie plant was working to its full capacity the output was 15,000,000 gallons a year.

In making the cordial, the monks gathered the dozen different species of herbs which were required to give the right blend These were first thoroughly dried, in the storehouse, being spread out on the floor, and exposed to air currents. The different herbs were then placed in spring water in separate vats, which were heated by wood fires—this for extracting the juice. The tanks were covered and the steeping process occupied about twenty-four hours, when the juice was drained off through pipes in the lower parts of the cooling vats. Next the liquid was distilled, the process being quite similar to the distillation of whiskey.

"Made in Germany"

Schulz made typewriter ribbons in a factory near Berlin. But he couldn't make them quite as good as the imported American ribbons. At least, he found that stationers and office supply dealers sold more American ribbons than they did of his, even though his ribbons were cheaper.

"There must be some reason," said Schulz, "why Germans are willing to pay more for American ribbons. I must find out why."

Did he engage a chemist? Did he snoop around in American ribbon factories, trying to find out how ribbons are made in America? Did he bribe workmen to reveal a precious trade secret?

No.

Schulz simply sent a few American ribbons and some of his own ribbons to the Koenigliches Material-Pruefungsamt – the Royal Laboratory for Testing Materials. In a few weeks he received a report in which he was told that the life of an American ribbon was twice as long as his own, that the fabric of the American ribbon was composed of this and that material and had a tensile strength three times as great as Schulz's, that the ink of the American ribbon was composed of such and such chemicals and pigments, with the result that its record was legible for a longer time and absolutely light-proof.

This is the kind of work that the Koenigliches Material-Pruefungsamt does for any German manufacturer. It gives expert information to him who is entitled to it, and at a price that doesn't begin to pay for the elaborate scientific investigation involved. Whether it be a girder for a bridge, or a button for milady's shoe, that public laboratory tests anything, and tells the German what he must do to make it better and cheaper, if possible.

In the next number of the Scientific American we will publish an article by Mr. Waldemar Kaempffert, Managing Editor of the Scientific American, on this remarkable institution.

We sent Mr. Kaempffert to Europe in order to study the part that science plays in German business and public affairs. His article on the Koenigliches Material-Pruefangsamt will be the first of a series in which new phases of German science and commerce and education will be revealed.

After you have read the series you will feel that "Made in Germany" means a good deal more than mere cheapness; that there may be far more science in the cheap German penknife bought on the street corner than you may suspect; that science, and not simply cheap labor, has made Germany a great commercial nation, and the German city the best-governed municipality in the world.

Watch the Scientific American advertising pages for announcements of the articles still to appear.

Then came the blending of the different extracts into the secret composition that has given chartreuse the flavor and the exhilarating effect which has made it famous This, the most delicate process, was supervised by the director; and before it was performed, mass was observed to sanctify the product

It is not generally known that three forms of the liqueur were manufactured at the chartreuse establishment, the green and the yellow chartreuse all know, but there is a much weaker extract, the white chartreuse, which was drunk with water by all the employees of the monastery, and was given to the stranger who accepted the hospitality of La Grande Chartreuse for a meal

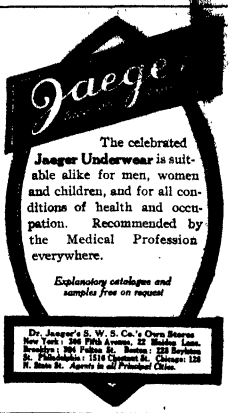
Until seven years ago the Carthusians kept up their industry They also worked farms; built schools and churches for the peasants, and laid out some of the finest roadways in Europe In 1904 the French government seized their property, forced out the Carthusians and since then have been making the liqueur—but it is merely a poor imitation of the brew prepared by the monks

NEW BOOKS, ETC.

THE COPPER HANDBOOK 1910-1911 Vol. X Compiled and published by Horace J Stevens Houghton, Michigan 8vo; 1902 pp

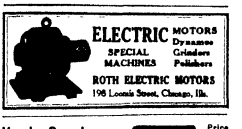
In "The Copper Handbook" we find a vast amount of information, both historical and timely Copper in its geological, chemical, and mineralogical aspects, its mining, milling, and concentrating, its hydrometallurgy, pyrometallurgy, and electrometallurgy, its alloys; the various grades, uses, and substitutes, a glossary of mining terms, chapters on the copper deposits of the Americas, of Europe, Africa, Asia, and Australia, a section of reliable and valuable statistics—in a word, we have a handbook crammed with facts pertaining to copper in its relation to industry, and to the industries Three-fourths of the space is taken up by an alphabetical presentment of the copper mines of the world, their location, date of organization, capitalization a description of shafts and levels, the nature and extent of deposits and present condition of activity—many being characterized as "idle" for years "idle and apparently moribund," and "dead" There must be upward of 9,000 mines described in this section of the work

THE ART OF LIFE The Way to Health and Longivity By Jogender Lal Chundra, L. M. S. Calcutta, India. Published by the Author, 5, Gopee Krishto Paul's Lane, 1911



The spelling of the subtitle is the author's In spite of the quaint English and fantastic spelling, Dr Chundra's curious little work is on the whole sane and progressive Drugs and drug treatments, while not entirely condemned, are subordinated to hygienic and dietetic principles The papers embody, among other themes a distinct contribution as to the value of common salt in the system, a survey of the diseases most prevalent in India, with notes on their geographical distribution and the conditions which favor them, and an incursion into so called "personal magnetism," colored, of course, by the Oriental viewpoint and philosophy

KING ARTHUR AND HIS KNIGHTS An Abridgment of Le Morte d'Arthur Edited by Henry Burrowes Lathrop. Illustrated by Reginald Birch New York The Baker & Taylor Company, 8vo Price, $1 50 net



Emphasis is laid upon the fact that this is not a series of excerpts from the original, but a careful abridgment in which the utmost has been done to retain in one volume of moderate size all the vivid coloring and incident of Malory's narrative The story of the Morte d'Arthur is told, substantially as Malory told it, in a connected series of vital episodes that can not fail to appeal strongly to young people Indeed, the sole purpose is to bring within the scope of youthful interest what is truthfully claimed to be the most delightful record of its kind which the English language has to offer

ANIMAL INTELLIGENCE Experimental Studies By Edward L Thorndike New York The Macmillan Company, 1911. 8vo, 297 pp; diagrams.

The author here presents in one volume a number of monographs which have been published separately and as papers in scientific periodicals His avowed purpose is to make accessible to students of biology and psychology his own experiments in animal intellect and behavior His research has led him to deprecate the employment of introspection as the chief method of psychology, which he prefers to regard as largely the science of behavior and a virtual extension of physiology. The experiments are primary and simple, but, like all simple things of this kind, illuminate the higher phases of being for those who are able to read their symbolism aright.

Learn Watchmaking
We teach it thoroughly in a many months as it formerly took years. Does away with tedious apprenticeship. Monday starting. Positions when graduated. Easy terms. Send for catalog.
ST. LOUIS WATCHMAKING SCHOOL, St. Louis, Mo.

THE BEST LIGHT
More brilliant than electricity or acetylene and cheaper than kerosene. Costs 2½ cents per week. Casts no shadow. Most perfect light for stores, factories, churches, public halls or the home. Makes and burns its own gas. Simple, durable and handsome. In use in every civilized country in the world. No dirt. No grease. No odor. Over five hundred different styles. Agents wanted everywhere. Write for catalog and prices.
THE BEST LIGHT CO.
57 E. 8th St., Canton, O.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12582) E McGee asks Would you be so kind as to give me an explanation of a statement made by Carhart and Chute in regard to the transformation of energy. They say: "The energy of the solar system is becoming all the time less and less available." A You omit one very important word in making your quotation from Carhart and Chute's Physics page 77. That word is "*therefore*." The sentence as given in the book is as follows: "The energy of the solar system is therefore all the time becoming less and less available." *Therefore* refers back to what has preceded. The radiated energy of the sun and other kinetic energy which is employed in doing work in nature or for man's needs, is *useful* energy. And also is useless and becomes waste heat. So the authors say therefore the amount of energy which is available for useful purposes is all the time becoming less and less. It seems to be a plain statement. The sun is radiating heat all the time into space, and this heat does not, so far as we can determine do any useful work. It reduces the available energy of the sun and is lost to us. There is less that we can have, less that is available.

(12583) R J M. asks Why does silver or silverware, when placed in an aluminum vessel with boiling water come out with a brilliant appearance as if new? Please give me the reason. A The cleansing of silver as you describe is an electrical process. A feeble electric current is produced between the silver and the metal pan and a new and fresh surface of the silver is exposed.

(12584) H E asks An argument arose regarding the following questions and I would be pleased if you would give me some information regarding same. What is the horse power of an engine 10 × 10 at 100 pounds pressure? If a suitable size low pressure be added to a 10 × 10 engine at 100 pounds pressure, what horse power would it develop? A Your question involves a large part of the theory of steam engineering. The horse power of the engine depends upon the speed of the engine (which you do not give) as well as upon the cut-off and consequent expansion and mean effective pressure, which latter is at ways less than the initial or boiler pressure. If a 10 × 10 engine is operated at one quarter cut-off and 100 pounds steam pressure by gage, the mean effective pressure (disregarding all losses) is 48½ pounds above vacuum and the pressure at the end of the stroke will be 25 pounds above vacuum. If the steam is exhausted at the above 25 pounds pressure the horse power of the engine will be about 17½. If however, this steam is now turned into a low pressure cylinder 20 inches diameter and 10 inch stroke, an approximate horse power of 17½ can be developed by expanding the steam to a low terminal pressure and exhausting into a condenser. The engine has now become a compound. But the same power could be developed (theoretically) by operating the low pressure cylinder alone at 1/10 cut-off and omitting the high pressure cylinder. The only advantage in using the two cylinders that is a compound engine is the higher theoretical economy due to expanding the hottest steam in a cylinder which is hotter, on the average, than the temperature of the second cylinder in which cooler steam is worked. If an engine could be made with a single cylinder of some imaginary material without any conductivity or capacity for heating it would do all that a compound engine could do. If a glass cylinder were possible to operate, there would be no advantage in point of economy in compound engines, as a single large cylinder of glass would do all the work of a series of two, three, or more of the heat-absorbing metal like iron, brass, and the like.

(12585) A B F says. I would be pleased to know if the combination of gasoline and coal oil (as used in lamps) in a gasoline engine, will produce more power than gasoline alone. Please give B T U, of gasoline, also of naphtha and coal oil. A Gasoline and kerosene have different specific gravities, and if mixed for use in an engine, gasoline will evaporate first and leave the heavier part of the coal oil for the last. The kerosene has a greater fuel value than gasoline per gallon, though very closely the same per pound. Kerosene is a cheaper fuel than gasoline, both because of its slightly greater heat value and because of its much lower cost per gallon. The fuel values of the various petroleum products, such as gasoline, benzine, kerosene, etc., are over 20,000 B T U per pound, and differ little, one from the other.

The Scientific American Cyclopedia of Formulas

The Most Complete and Authoritative Book of Receipts Published

Partly Based on the Twenty Eighth Edition of
The Scientific American Cyclopedia of Receipts, Notes and Queries
Edited by **ALBERT A. HOPKINS,** Query Editor of the Scientific American

THIS is practically a ***new book*** and has called for the work of a corps of specialists for more than two years. Over 15,000 of the most useful formulas and processes, carefully selected from a collection of nearly 150,000, are contained in this most valuable volume, nearly every branch of the useful arts being represented. Never before has such a large collection of really valuable formulas, useful to everyone, been offered to the public. The formulas are classified and arranged into chapters containing related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired.

"As Indispensable as a Dictionary and More Useful"

Following is a List of the Chapters

I. Accidents and Emergencies.
II. Agriculture.
III. Alloys and Amalgams.
IV. Art and Artists' Materials.
V Beverages, Non-Alcoholic and Alcoholic
VI Cleansing, Bleaching, Renovating and Protecting.
VII. Cements, Glues, Pastes and Mucilages.
VIII. Coloring of Metals, Bronzing, etc.
IX. Dyeing.
X. Electrometallurgy and Coating of Metals.
XI. Glass.
XII. Heat Treatment of Metals.
XIII. Household Formulas.
XIV. Ice Cream and Confectionery.
XV Insecticides, Extermination of Vermin
XVI. Lapidary Art, Bone, Ivory, etc.
XVII Leather.
XVIII. Lubricants.
XIX Paints, Varnishes, etc.
XX. Photography.
XXI. Preserving, Canning, Pickling, etc.
XXII Rubber, Gutta-Percha and Celluloid
XXIII. Soaps and Candles.
XXIV Soldering.
XXV. Toilet Preparations, including Perfumery.
XXVI. Waterproofing and Fireproofing.
XXVII. Writing Material.
Appendix Miscellaneous Formulas; Chemical Manipulation; Weights and Measures, Index.

ANNUAL MOTOR NUMBER

MOTOR CARS MOTOR TRUCKS MOTOR BOATS MOTOR CYCLES

JANUARY MAGAZINE NUMBER OF THE SCIENTIFIC AMERICAN

ISSUE OF JANUARY 6, 1912

Although we are well past the dawn of the "hydrocarbon age," we have not yet reached the meridian period. Each year there are new developments making for the betterment of motor-driven land and water vehicles. The improvements that are to be brought out in 1912 are exceptionally interesting and will be outlined in detail in this number. The following articles will appear:

Selection of a Motor Truck

In what respect do leading types of motor trucks for 1912 differ mechanically? How can the owner best protect his investment? What are the costs of upkeep and operation as compared with those of horse-drawn trucks? Can truck chauffeurs be made of ordinary teamsters? These are vital questions to the intending purchaser of motor trucks, which will be ably discussed.

Will Rubber Tires be Supplanted?

While tire manufacturers are doing everything that is humanly possible with rubber and fabric, yet, undoubtedly, there is no feature of a motor car that gives the owner more concern than the tires. The ability of rubber to stand up under the terrific shocks and wearing grind of service is a marvel. Hundreds of inventors have been busy at the task for years, no substitute for the rubber tire has yet been developed to such a degree as to supplant the standard pneumatic tire. Just what has been done in the past, and what promises are held for the future, will be brought out in this article.

The New God of War—Gasoline

In this article the prominent place occupied by the automobile in European military maneuvers is described. In the United States the armored automobile has been entirely neglected. In Germany in time of war every car in the country, private as well as public, is placed at the beck and call of the Government.

Auxiliary Uses for Motor Vehicle Engines

Herein are described a number of novel uses for the engine of a motor truck or an automobile.

The Comparative Cost of Light and Heavy Cars

This question is debated by a man who has made painstaking and impartial comparison of every detail of his personal expenses in connection with two cars, one a typical light car, and the other a standard heavy car.

Making the Starting Crank Obsolete

One of the most noticeable features of the 1912 car will be the absence of a starting crank in front of the radiator. The desirability of providing a means for starting the car from the driver's seat was expressed years ago, and its necessity has been urged more clamorously each year. Now, suddenly, a score of different self-starters have been developed, and the majority of manufacturers are going to bring out their 1912 cars with some sort of a self-starting mechanism. The leading types of self-starters will be explained so that any automobile owner can understand them.

Driving the Car at Night

To obtain the full value of a motor car, it must be available for service at night as well as during the day time. There is much more to safe night-riding than a pair of powerful headlights. There are new developments which every automobilist should know.

The Easy Riding Car

The pleasure vehicle has now become so standardized that the riding qualities of an automobile receive much more attention than heretofore. As a consequence, designers have been devoting much thought to the springs, shock absorbers, upholstering, the balance and hang of the body, and all the features that enter into the making of a comfortable car. The prospective purchaser should know that the distribution of weight on a car is an important factor in making it "stick to the road." A badly-bal d car will possess poor traction qualities owing to the tendency of the rear wheels to bounce off the road's surface.

A Fertile Field for Inventors

Under this subject are detailed many ingenious devices that inventors have developed of late for use on automobiles.

Lessons in Everyday Motor Boat Designs

The racing motor boat is very properly considered a useless craft for pleasure purposes. In the present article, however, it is clearly brought out that the design of the pleasure boat has been materially improved by the development of the racer.

Motor-Cycle Developments

What is being done to improve that noisy, sputtering, two-wheeled vehicle? Among the prominent features for 1912 are footstarters, multiple jet carburetors for slower running in cities, improved mufflers, and floating seats to make riding more comfortable.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

A Warning

IN view of many inquiries received from subscribers and advertisers relative to a new edition of the Encyclopedia Americana and certain other publications issued or sold by the Americana Company or "Scientific American Compiling Department," Messrs. Munn & Co., Incorporated, state that such publications have no connection whatever with the SCIENTIFIC AMERICAN published by them, and that Messrs. Munn & Co., Incorporated, have no interest of any sort in the business of the Americana Company or of the so-called "Scientific American Compiling Department." The use of the words "Scientific American" in connection with the latter is without the approval or consent of Messrs. Munn & Co., Incorporated, and notice has been served upon the Americana Company that the use of the above title must be discontinued.

Retrospect of the Year 1911

Civil Engineering.

IN any review of the engineering progress of the past year, the construction of the Panama Canal assumes the position of importance. Not alone is this the greatest single engineering work of its kind, but it is notable for the fact that it is being done at an accelerating speed, and will be completed long before the date predicted. In this respect, it stands almost alone among American engineering works of great magnitude. According to the report of the chief engineer, the Gatun dam will be finished during the summer of 1912, the locks at Gatun about the same time, the locks on the Pacific side in the fall of the same year, while the Culebra cut, and the channel entrances on each ocean, will be completed by July 1st, 1913, at which date eighteen months before the time originally estimated, shipping will be able to pass through the canal from ocean to ocean. Next in importance is the New York State Barge Canal upon which during the year satisfactory progress has been made. Practically the whole of the canel is under construction, and both the concrete work at the locks and the work of excavation are being pushed forward at a rate which gives promise that within a few years time this valuable addition to the transportation facilities between the Great Lakes and the Atlantic seaboard will be open for service. The proposed Pittsburgh-Lake Erie canal has been brought again into public notice, and it is now proposed that its cost of fifty million dollars be divided between the three States which are interested, namely, Ohio, Pennsylvania, and West Virginia, the control to be vested in a joint commission. There has been a movement on foot in Russia to build a canal, with a depth of 14 feet, between the Black Sea and the Baltic, utilizing some 900 miles of the bed of the West Dwina and a thousand miles of the bed of the Dnieper. The estimated cost is $150,000,000. The greatest water-supply project in the world, namely, that for bringing the water of the Catskill region to New York city, has made great advance during the past year. The Ashokan dam is nearing completion; work upon the ninety miles of 17-foot aqueduct has been opened up upon many new sections; the wonderful siphon by which the water will be conveyed beneath the Hudson at Storm King is so far advanced that the vertical shafts on opposite sides of the river have been sunk to a depth of 1,200 feet, and the boring of the connecting horizontal tunnel is making good progress. The contracts have been let for the construction of the terminal tunnel which will extend the full length of Manhattan Island at depths of from 200 to 700 feet. Moreover, the prospects are that within a year or two, Catskill water will be fed to the Croton reservoir, whence it will be available for distribution in New York. One of the most beneficent and little-understood works of the United States is the reclamation by irrigation of arid lands. Already there has been invested about sixty million dollars in this work, and during the year it has been increased at the rate of about one million dollars per month. The scheme of reclamation includes the construction of some of the greatest dams and largest reservoirs in existence. Perhaps the most notable event in this work was the dedication of the Roosevelt dam, which was celebrated on March 18th. The structure is 282 feet 8 inches high, and it impounds sufficient water to cover 1,284,000 acres to a depth of one foot. At the present time, water can be supplied to about one million out of the three million acres which the completed scheme will cover. Another great hydraulic work in this country which has been advanced during the year is that of grading the Everglades in Florida, by which a vast tract of fertile swamp land will be brought under cultivation. In the field of bridge engineering, the most notable event was the letting by the Canadian Government of a contract for the construction of a new Quebec bridge to take the place of the one which failed so disastrously a few years ago. The structure will be what is known as the "K" web system, and the cantilevers will carry a Pratt-truss suspended span, 640 feet in length. Nickel steel will be used in the cantilever arms; the suspended span, the anchor arms, and the members immediately over the main pier, together with the floor system, will be built of carbon steel. Toward the close of the year the contract was let for the construction of the four-track Hell Gate bridge, which will connect the Long Island Railroad system with the railroad systems of the main land. The most notable feature will be the main span of 1,000 feet, which will be the longest and heaviest arched span in existence. In the arch bridge alone will be 18,000 tons of steel, and it will take 70,000 tons for the whole structure, whose total length will be three miles.

Electrical Engineering.

During the year, the field of electrical engineering has steadily enlarged its borders. The progress has been in the direction, not so much of the development of new inventions and applications, as in the broadening of the scope of those already established. Undoubtedly, the most notable advance is that which has been made in electro-metallurgy and electro-chemistry. It is sufficient here to note the increasing application of electricity to the electrolysis of salts, the production of metallic aluminium and sodium, the production of calcium carbide, in all of which industries, and particularly the production of aluminium the progress is by leaps and bounds. The refining of metals by electrolytic action has been responsible during the past year alone for placing over one hundred million dollars' worth of pure copper on the market. In the more novel applications of electricity to the arts, the electric reduction of iron ore has been the most prominent, and among the several ingenious designs of electric furnaces there are two or three which give promise of competing commercially with the present gas and coal furnaces. In the field of electric lighting, the tungsten lamp continues to win popular approval; and this can be readily understood when we remember that a 16-candle-power carbon filament lamp requires 56 watts for its operation, whereas a 20-candle-power tungsten lamp demands only 25 watts. It is gratifying to know that during the year the united efforts of the electric lighting companies have succeeded in producing a drawn-wire tungsten filament of great toughness and durability. In the field of transportation, electricity continues to be the supreme power for urban and suburban service, and note should be made of the fact that the Edison storage battery cars which have been operating during the year in New York city have been giving reliable and satisfactory service. The application of electric traction to steam roads is not making the progress which was expected when the New York Central and New Haven installations had proved how reliable and punctual a service could be given. Figures of cost are difficult to obtain; but, as the report on the proposed electrification of Boston suburban roads showed, the first cost of these changes from steam to electric power is so great as to discourage investments of this character. There is a consensus of opinion that the alternating-current, overhead trolley will be used for long distance service, and the direct-current third-rail system for terminal and suburban. The utilization of water powers by the construction of large hydro-electric plants continues to make a... advance, the most notable work of the year being the vast dam which is being built across the Mississippi River at Keokuk, Iowa. The dam will stretch... seven-eighths of a mile across the river, rising 82 ... above the river bed. At one end of the dam will be the lock gates and a power house 1,400 feet in length, in which will be mounted thirty hydraulic-electric units. The initial installation of 120,000 horse-power is to be completed in July, 1913. A promising field for the application of electric power is that of agriculture. It has been shown in the pages of the SCIENTIFIC AMERICAN what possibilities lie at the very doors of the farmer in the many abandoned mills and reservoirs, some of which, by a little reconstruction and adjustment, may be turned into central stations, from which power can be furnished to surrounding farms at a not prohibitive cost.

Railroads.

In the preceding section we have touched upon the progress of electricity as a motive power for steam railroads. The probability of the substitution of electricity for steam on the score of reduced cost of operation has been somewhat lessened by the extended application of superheat to locomotives. It now looks as though superheat will achieve those economies which, at least in American practice, compounding has failed to secure. The simple engine always possessed certain practical advantages over the compound, and the addition of superheat makes it possible to secure equal and often greater fuel economy in a locomotive of the simple type, than is possible in a non-superheat compound. The increasing application of superheat may easily be set down as the most important development in locomotive practice of the past year. In spite of predictions to the contrary, the weight and size of American locomotives, and, to a less degree, of foreign locomotives, continue to increase. To-day, in the huge engines built for the Santa Fe Railroad, we surely have reached the limit. A passenger locomotive for hauling fast passenger trains weighs 188 tons without the tender. The Santa Fe Mallet freight locomotive, with twenty-four wheels, twenty of which are drivers, weighs 308 tons, and with the tender, 425 tons, its length over all being 120½ feet. The fatal wrecking of the Washington express on the New Haven road, near Bridgeport, when it was taking a crossover, has drawn attention to the necessity of making crossovers from express to local tracks longer and of easier curvature, so that they may be taken at high speed without risk of derailment. Notable events of the year were the opening of the Pennsylvania terminal and tunnels at New York and of the handsome terminal of the Chicago & Northwestern at Chicago. Great progress has been made with the Grand Central terminal of the New York Central Railroad at New York. The excavation is nearly completed, and the greater part of the steel work of the station building has been erected. This terminal, with its total area of 69⅜ acres, is equal in area to the four next largest terminals of the world, combined.

The Steam Engine.

In spite of the activity and great promise of its younger competitors, the steam engine, thanks to careful study of its principles and the best methods of construction, seems likely to hold its own as the principal prime mover for many years to come. The steam turbine, from the attitude of a competitor of the reciprocating engine, has passed into the position of its complement or useful ally. It is now understood that in the higher ranges of steam expansion, the reciprocating engine is supremely economical, just as the turbine is in the lower ranges. The installing of a low-pressure turbine between exhaust and condenser of the reciprocating engines, as we showed last year, increased the output of the New York subway power station 100 per cent, and increased the economy 150 per cent. Both on shore and at sea, the economic value of superheat is coming into increasing recognition, and economies of from 20 to 30 per cent and more have been realised in a wide variety of installations. An interesting development was made public during the year in the Tesla turbine, which consists of a series of flat steel disks mounted on a shaft within a casing, the steam being delivered at high velocity at the periphery of the disks and flowing between them in spiral paths, to exhaust through ports at their center. Tesla depends upon the properties of adhesion and viscosity of the steam for securing the desired torque on the shaft. A curious situation has developed in the United States navy, where there is an unmistakable disposition to return to the reciprocating engine as the drive for our future battleships. This attitude has resulted from observation of the sister battleships, "Delaware" and "North Dakota," and the economy of 30 to 40 per cent shown by the reciprocating engines

the "Delaware" over the turbines of the "North Dakota," when the two ships were steaming in column during several thousand miles of cruising. The action of the department is, we consider, rather precipitate. The engines of the "North Dakota" are of a rather early type; more modern turbines would reduce the difference to 20 per cent, and a combination of cruising reciprocating engines and turbines would, we believe, wipe out the difference altogether, leaving the balance of practical advantages heavily on the side of the turbine-engined vessel.

Naval Development.

Toward the close of the year, there was mobilized in the North River, New York, at a few weeks' notice, the most powerful fleet that ever assembled in American waters. Over one hundred ships were drawn up in several parallel lines between the New York and New Jersey shores; and that the object of the Navy Department of popularizing the navy by showing to the people the actual ships themselves, was achieved, was proved by the vast throngs that flocked into the city from the surrounding country to witness the truly majestic spectacle. The most imposing element of the display was the line of twenty-six battleships, extending unbroken for six and a half miles, in which was included the six dreadnoughts that have been completed for the navy. Of more importance, however, than material, is personnel; and the significance of that array could be appreciated only by the naval man himself or by those who, like the writer, had been privileged to live aboard one of the ships of the navy when the fleet was engaged in the regular routine of daily life, and in the supremely important work of battle practice. In discipline, *morale* and practical efficiency, the navy has never stood as high as it does to-day. We have so recently devoted a special number to this subject, that it is sufficient for the purposes of the present review, to refer to the various articles in that issue, written by leading officers of the Department for the purposes of telling the people of the United States just what kind of a navy it is that we possess. The American type of dreadnought, with center-line turrets, and guns firing above the roofs of adjacent turrets, has become standard throughout the world; and the guns so admirably placed are being served so well, that we believe our ships are able to make accurate shooting at ranges that are never attempted by any foreign fleets. The one great fault with our navy is that it is not proportionate to the wealth and responsibilities of the country which it protects. The general board at Washington, after a conservative review of conditions, have decided that, in order to maintain a navy adequate to our wealth and population, we should build four ships (battleships or battle cruisers) every year. Our present inadequate increase of two battleships per year will, in five years' time, make it possible for our nearest competitor among the European naval powers to challenge the Monroe Doctrine, knowing that its strength in dreadnought ships, as compared with our own, is 100 per cent greater

In a general review of naval development, there is noticeable a steady increase in the size of the battleship and the caliber of her guns. The largest ships have reached a displacement of 28,000 tons and over and carry 13.5 and 14-inch guns. There are signs of a reaction in favor of smaller ships, but we doubt if it will take place, so many and so great are the advantages conferred by the possession of big units. A noteworthy feature is the growth in popularity of battle-cruisers, ships of 28 to 30 knots speed, well armed, well protected, and with a large radius of action. We consider that the weak point in the make-up of our navy is its lack of any ships of this class. Our little 25-knot "Chesters" and "Salems" would be as defenseless in the presence of such vessels as so many chickens before a flock of hawks. They would not dare to venture within range of a screen of battle-cruiser scouts; for that would mean capture, or speedy destruction by 12 and 13.5-inch guns. Moreover, a squadron of 28-knot battle-cruisers would prove to be an extremely complicating factor in battle tactics, when used against an enemy which possessed no vessels of this class. The destroyer holds its own, and seems to increase in importance. Four destroyers to each battleship is a standard in European navies which we should make haste to follow. The submarine is increasing rapidly in size, offensive quality, and, most important of all, in sea-keeping qualities and radius of action. It is our belief that the submarine, or some modification of it, will see a development during the next decade which will possibly enable it to challenge the present supremacy of the battleship. Although the existing war between Italy and Turkey is necessarily, because of the practical absence of a modern Turkish navy, a military war, it has served to emphasize in a striking degree the importance of the command of the sea. Italy is not only able to localise the war in Tripoli, but is in a position to completely prevent the sending of necessary reinforcement and supplies to the Turkish army at the seat of war.

The Merchant Marine.

In any American who is possessed of a true patriotism, the subject of the American merchant marine must necessarily beget feelings of regret if not of positive humiliation. Year by year the flag of this country becomes scarcer upon the high seas, and it may truly be said that matters have come to such a sorry pass that unless this nation bestirs itself to a sense of its duties and opportunities, its flag must ultimately disappear from the seven seas. Let the facts of total tonnage speak for themselves. In 1789, the United States possessed 124,000 tons of merchant shipping engaged in foreign trade. In 1809, the total had risen to 667,000 tons. Sixty years later, we led the world, with a total of 2,379,000 tons. In 1910, the total had fallen to 782,000 tons, which is but a little over 100,000 tons more than we had afloat at the beginning of the nineteenth century. The one hopeful sign is the fact that the importance of the subject is continuously impressed upon the public mind. Out of the many suggestions which are being offered for the resuscitation of our merchant marine, there are two which seem to be practical, and would probably prove to be thoroughly effective. The first is the institution of a system of preferential duties in favor of American-built ships and against ships flying the flag of a foreign country. It was under this policy that the merchant marine of the young republic prospered in the first forty years of its existence, and we believe that like causes would produce like results in the present day. The other remedy, which is connected with the opening of the Panama Canal, proposes to bring all American shipping, sailing between Atlantic and Pacific ports by way of the Panama Canal, under the regulations which protect our coastwise shipping. Ocean-going steamships continue to increase in size, and it is an extraordinary fact that the increase is at an accelerating rate. When the "Mauretania" and "Lusitania," each 790 feet in length, were launched, it was predicted that the limit of size had been reached, but during the year there entered the port of New York, on her maiden voyage, a ship which is 882½ feet in length, and which exceeds the displacement of the two great Cunarders by from 15,000 to 20,000 tons, according to the degree of loading. In addition to her great size, the "Olympic" is notable for being driven by a combination of reciprocating engines and turbines. Her speed of 22 knots is, of course considerably less than that of the Cunarders, which must remain the fastest of the trans-Atlantic liners until such time, possibly, as the internal-combustion engine has rendered a further advance in speed possible. The end is not yet, however, in this matter of size. The Hamburg-American Company is building two vessels, the "Imperator" and a sister ship, which are to be just under 900 feet in length, the Cunard Company is constructing the "Aquitania," which will slightly exceed 900 feet; and, in answer to our inquiry, the leading officials of the White Star Company inform us that an order has been placed with the Belfast firm for the construction of an 18-knot ship, 1,000 feet long, 100 feet wide, to be driven by combined turbines and reciprocating engines of 55,000 horse-power. The limit on length and size is placed by the length of piers and depth of harbor entrances, and before the "Olympic" could dock at New York, it was necessary to make a temporary extension of the pier (by permission of the War Department) of 100 feet, which, under the terms of the permit, must be removed in twelve months from the present time. From the earliest days of the modern steamship, attempts have been made to check rolling at sea. The most promising device to-day is that of Frahm, who has installed on several vessels anti-rolling water tanks, which apparently have done much to reduce this unpleasant source of discomfort to the sea voyager. The most important development in marine engineering just now, outside of that of increase of size, is the attempt to utilise the internal combustion engine for propulsion, a subject which is treated at fuller length in the present review under the head of the internal combustion engine. Mention should be made of the effort to reconcile turbine speed with propeller speed by the interposition of an intermediate reducing gear, the most noteworthy of which is the installation on the United States collier "Neptune," a 14-knot vessel of 19,360 tons displacement. The turbine running at 1,220 revolutions per minute, drives the propellers at 185 revolutions, through an intermediate, mechanical-reducing gear of the Westinghouse-McAlpine type, which has shown an efficiency of 98 per cent in a shop test. Trials of this vessel are still in progress. A sister ship to the "Neptune," the "Jupiter," is being equipped with a turbo-generator, running at 2,000 revolutions per minute, the power from which will be transmitted to the propeller shaft, with a speed reduction of 18 to 1, and an estimated efficiency of transmission of 91 per cent. Whether reduction gears or a combination of reciprocating engines and turbines will prove to be the better solution of the marine turbine problem, will probably be demonstrated during the coming year.

Internal Combustion Engines.

In the field of prime movers, the internal combustion engine undoubtedly presents the greatest promise, both as to the wide field of its application and the great reduction in space occupied and consumption of fuel per unit of work done. Although the producer-gas engine has given promising results, both in marine and stationary plants, it is to the heavy oil engine of the Diesel type that the engineering world is looking for immediate developments. Because of its reliability and simplicity of operation, the Diesel engine has won recognition as the heavy oil engine of the future. Nowhere is it holding attention just now so closely as in the navy and the merchant marine. For marine work, it offers many and most valuable advantages. Tests on large engines of this type have shown the remarkable economy of 0.38 pound of crude oil fuel per brake horse-power hour, and the marine engines now in use average from 0.40 to 0.41 pound of fuel per brake horse-power when running under full load. In addition to fuel economy there is the great advantage that the space formerly occupied by the boilers and coal bunkers is free for cargo carrying or on warships for the installation of larger magazine, oil, or, on warships, for the installation of larger magazines and store rooms. The fuel may be piped directly to the tanks and stored in the double bottom, a speedy and cleanly operation compared with the slow and dirty work of coaling a ship. The most notable marine installation is that aboard the vessel which is now being built by the Hamburg American Line for their transatlantic service. This ship of 9,000 tons, will be driven by twin engines, each of 1,500 horse power, with which the ship is expected to develop a speed of 11 to 12 knots.

Astronomy.

By far the most noteworthy astronomical event of the year was the appearance of the new star discovered by Espin. Although the nova was actually first discovered on December 20th, 1910, the phenomenon may fairly be considered an astronomical event of 1911. The star proved to be a typical nova which caused its sudden appearance probably to a collision between some cold, but, in the depth of space and a nebula or cluster of meteoric bodies.

The year was a year of comets. The body discovered by Kiess at Lick Observatory on July 6th was easily visible in an opera glass. Two weeks later, Prof. William Brooks of Geneva, N. Y., the veteran comet hunter, discovered a comet which came within thirty million miles of the earth, and which proved to be a fairly conspicuous object. The return of Encke's comet was watched with interest, because it has the shortest period of any known comet, returning to the sun every three and one-half years. Because it varies in brightness at each successive return in a very remarkable manner, and because its varying period of revolution proves that some other force than the attraction of the sun must act upon it. In the month of September two more comets were discovered, one by the Russian astronomer Bedjawsky, and the other by Quinnesset. Borelli's faint periodic comet, discovered in 1905, was observed on its return at some of the southern observatories.

On April 28th there was a total eclipse of the sun, which lasted almost five minutes, fairly long as solar eclipses go. Since the whole track of the shadow lay in the Pacific Ocean, only a few islands were available as stations, for which reason the number of expeditions sent to observe it were not numerous. The usual observations were made, and no startling new fact was revealed.

Prof. Stebbins of the University of Illinois who devotes his time to making very accurate measures of the brightness of the stars with an apparatus depending upon the change in the electrical resistance of selenium when light falls on it, took up the work of discovering new variables with his instrument. In this work he was successful finding no less than two. Thanks to Prof. Stebbins, we have reached a knowledge of systems such as Beta Aurigæ which it seemed almost impossible to have attained ten years ago.

Dr. Baker and Prof. Wendell showed that the star α Herculis is a close double with unequally bright components, revolving about each other in a nearly circular orbit in a period of 2 days, 1 hour and 15 minutes. Prof. Schlesinger on the basis of the observations of Dr. Baker and Prof. Wendell calculated the masses of the components and showed that its distance from us is equivalent to 200 light years.

Aviation.

Startling advances have been made in aviation during the past year. In the middle of January Eugene Ely flew from San Francisco to the cruiser "Pennsylvania," moored in the harbor, and alighted thereon later returning to the shore. This was the first trip from shore to ship, and return, ever made by an aero-

The Methods of Dust Extraction on Cotton-carding Engines

Safeguarding the Workingman's Health

By J. H. Crabtree

THE efficiency of cotton mills is intimately dependent upon the working conditions prevailing therein. Fresh, dustless atmosphere at a reasonable temperature is of paramount importance in promoting the welfare of the workers during their daily occupation.

How to clear the air in certain parts of these mills has for some time occupied the serious attention of employers. Several schemes, more or less effective, have been launched forth, but few have gone beyond the experimental stage. They are either too expensive or impracticable on a large scale.

The common plan until recently was to install fans in each carding-machine has two cylinders, one of which is 4 feet wide and makes 160 revolutions per minute, it follows that in a few hours the wires become surcharged with dust and short fibers. And if they were not stripped of these they would be so glutted with refuse that the machine would fail to do its work. Hence when the carding-engine has been in operation for two or three hours the process is stopped, and the two strippers bring up a cylindrical brush covered with wire bristles. This is placed in contact with each of the cylinders in turn, and revolved at a rapid rate.

The brush strips the wires of nearly all the short fibers which clogged up the interstices. It also roots out the dust and sticks which have been retained in the cotton up to its treatment in the carding-machine. When the stripping-brush has done its work, it is an easy matter to clean it by means of a hand-card. It contains short fibers only; the dust has passed into the air of the room in dense volumes.

Here, then, is the specific function of the new appliances—to prevent this dust pervading the air of the room. This is of greatest importance to the men who manipulate the brush. They must stand in close proximity while the brush is revolving. The volumes of dust pass into their nostrils, and much is unavoidably inhaled. This involves serious risk to the men, and in time, tells upon their physical strength. It is, indeed, seldom that strippers are able to follow their employment to a normal age of say 60 to 65 years. The work induces pulmonary troubles in some men at an early age.

The danger is, to some extent, mitigated where the men adopt the precaution of holding a tuft of clean cotton fiber, pressing it between the lips while stripping. This forms an old-fashioned respirator (Fig. 1), which is used daily by men who have often proved its value. Other men have recourse to specially-designed respirators, which are adapted to facial outline (Fig. 3), and preserve the mouth and nose from contact with dust. The fact that strippers have suffered acutely from their occupation has been definitely proved by investigations in various cotton towns where between 40 and 50 per cent have been found affected in varying degrees.

Fans, exhaust or ipdraught, have doubtless done much to purify the air of carding-rooms; but they do not touch dust-clouds for some time after the dust is generated. The result is that the dust becomes mixed with the air of the room and, after having affected the strippers close by, it is diffused in the room generally, and traverses the area where the women and girls are at work on the spinning-frames. There is a moderate amount of dusty material given off from the frames themselves in cotton mills. This in itself, however, does not occasion either inconvenience or injury. The new methods work on different lines from any before put into practice. Several of these are now in operation, but the general principle adopted is to collect the dust at the point of its generation and remove it by means of trunks to the external parts of the mill-premises or to inclosed dust-chambers.

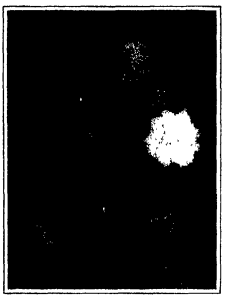

Fig. 1. Simple and primitive respirator. A tuft of cotton held between the lips.

Fig. 2.—Fixed dust extractors in series.

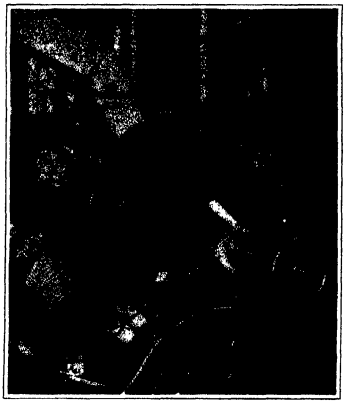

Fig. 4. "Traveling extractor," with stripping brush over the main cylinder of the carding machine.

Fig. 5.—Another form of fixed "dust extractors" in series. When stripping is completed the hood is raised in the vertical tube.

THE METHODS OF DUST EXTRACTION ON COTTON-CARDING ENGINES

of 15 to 24 inch diameter in wall-boxes or window-frames, at various parts of the room, and exhaust the impure or dusty air so as to change the atmosphere of the room three or four times during each day. Dust is generated in most carding rooms in such a degree as to be particularly injurious to the strippers. In card-rooms the raw cotton is combed, in machines known as "carding-engines," by a myriad of pointed wires attached to revolving cylinders.

A roll or "lap" of cotton is fixed on the front of this machine and it issues from the back as a thick woolly band of yarn with the fibers combed in one direction.

This machine makes the first semblance of a thread in the operations of a cotton mill. Between the lap and the thick yarn the cotton is passed over the cylinders covered with wires. Here the short fibers are held between the wires, the dust and small particles of the cotton-plant are also retained here. These millions of wire-points act much like an ordinary clothes

Fig. 6.—"Dust extractors" with automatic valves.

Fig. 7.—"Portable dust extractor."

THE METHODS OF DUST EXTRACTION ON COTTON-CARDING ENGINES

Several plans are at work in the cotton districts of Lancashire. By one of these (Fig 2) a dust-receiver is fixed over each carding-machine. This is as wide as the machine itself and has an opening about 2 inches wide; it bears a balanced lid by which the aperture can be opened and closed at the will of the stripper. The receiver is attached above to a carrier-tube running to the main air-trunk. In this an inclosed blower runs at 1,200 to 1,500 revolutions per minute. The blower will take care of forty to sixty carding-machines, and the additional mechanical power used is nominal.

The *modus operandi* is as follows: When the strippers place the revolving brush on a carding-machine, the receiver-lids of the whole series are closed except the one over this particular machine. Thus the total exhausting force of the blower is concentrated on one machine; and when the stripping begins, the air-currents about the aperture are strong enough to gather the dust as it is generated. The attendants require no cotton tufts or respirators, the dust is completely prevented from reaching their breathing organs.

Then the receiver-lid is closed, the brush removed to the next machine, another lid opened, and the process is repeated throughout the series of fifty or sixty machines.

Another method (Fig 4) has been devised, in which a single traveling receiver is available for each row of carding-machines. In cotton mills generally these machines are laid in parallel lines of ten to forty, with intervening spaces of 10 to 18 inches. It is therefore possible to build up carrier-tubes in line with the machines, and about four feet above them. On either side of the tube-line a rail is fixed to hold the grooved wheels of the traveling receiver.

The exhaust in this arrangement is maintained by a blower running at about 1,300 revolutions per minute. Over each carding-engine is an aperture in the

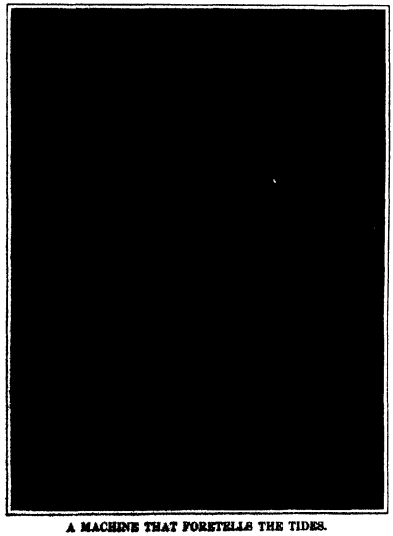
(Continued on page 404.)

New Tide-predicting Machine

By M. H. Talbott

UNCLE SAM'S new tide prophet is a machine which outclasses all human competitors; it is capable of doing in one day work which formerly required the services of sixty-five computers. It was invented by Mr. E. G. Fisher, of the United States Coast and Geodetic Survey, and is used to predict the height of the water at any instant on any date from one to two years in the future for every port in the United States and seventy of the principal ports of the world. This information is issued in the form of a book by the Coast and Geodetic Survey.

Tide predictions are based on local as well as astronomical conditions that influence the rise and fall of the ocean. At every port in the world there is an instrument which indicates these fluctuations by a curved line on a sheet of paper, and from a long series of such observed curves computers have evolved the average of each component at each place. The formula upon which this perfected machine is based includes thirty-seven of these components. There are a set of gears to represent the sun's influence, another to take the place of the moon, various other sets which act for the planetary movements, and still other sets which speak for local conditions.



The machine looks like a huge printing press. A skeleton frame of brass, steel, and iron occupies a space 11 feet long, 6 feet high, and 2 feet wide, and from the dial indicators in the front to the opposite end it is a maze of wheels, gears, pulleys, and chains.

There are three hundred gear wheels and pulleys in the machine. These are arranged in two main sections, one representing the time, the other the height of tide. Two chains, each permanently fastened at one end, run through each section, and their free ends are attached to indicating devices.

The operator beginning a set of predictions adjusts the eccentrics connected with each set of gears. By turning a crank he causes the wheels to rise or descend, thus lengthening or shortening the free end of the chain. This variation appears on the dials at the front of the machine, one pointer showing the height of water in feet and tenths; the other the day, hour, and minute of the occurrence. An electrical device stops the machine whenever a high or low water is indicated.

While the operator is recording these figures, the machine is doing a still more detailed work. A strip of paper 6 inches wide and 380 feet long is moving automatically across the face of the machine, and while one pen is marking the hours and exact times of highest and lowest waters, another pen is tracing a curved line which shows the gradual rise and fall.

The information turned out by this machine is sought by the marine engineer who wishes to calculate for improvements, and the hydrographic surveyor who is laying plans for future surveys, as it enables him to know the depth and time of high and low water on any date a year or two in advance.

A MACHINE THAT FORETELLS THE TIDES.

Weighting of Silk

IT is much to be regretted that many unscrupulous manufacturers resort to weighting or "loading" raw silk in the dyeing process, to such an extent as to render it a very uncertain and treacherous fabric with a tendency to split and crack even when carefully folded and laid away. In this dyeing process the natural gum of the silkworm is first removed from the silk by a method of "stripping," as it is called, in order that the raw material may properly take and hold the dye. This causes a loss of weight which dyers have always sought to restore, but instead of being content with doing this, the thrown silk is dipped into a solution of bichloride of tin, nitrate of iron, or some other chemical compound for the purpose of giving it more weight than that lost in the stripping process, so that a hundredweight of silk in the raw state is often made to weigh three, or even four hundred pounds when the dyeing is completed. As raw silk is bought and sold by the pound, the gain to the manufacturer is obvious. This operation makes the silk more valuable, but destroys the durability of the filaments.

Stretching the threads by steaming, so that a given weight will weave a greater number of yards, and the addition of chemicals to give it an unnatural luster are other processes that prove profitable to manufacturers, but costly to consumers.

It is a mistaken idea with many people that the heavy silks are the best and most durable. Just the reverse is true. The light weight, or "pure dye silks" as they are termed, are much stronger and more durable, as only enough added weight is given to this class of silks, in the dyeing, to replace the loss in the stripping process.

The use of inferior and destructive dyes is another method equally as common and equally as reprehensible, by which many manufacturers impose upon the consumers in the dyeing of silk.

Charles Edwin Bessey

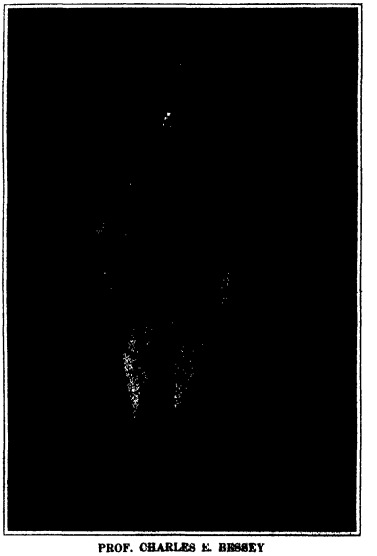
The New President of the American Association for the Advancement of Science

By Marcus Benjamin, Ph.D.

AFTER an absence of eight years the American Association for the Advancement of Science returns to Washington for its annual meeting. In 1903 the presiding officer was the chemist, Ira Remsen, who still guides with consummate skill the fortunes of the Johns Hopkins University. At the present meeting a botanist, who for forty years has faithfully attended the gatherings of the Association, will preside over its proceedings.

Charles Edwin Bessey was born in Milton Township, Wayne County, Ohio, on May 21st, 1845. His ancestry on his father's side is of French origin; for the Besseys, as the name was formerly written, were Huguenots who fled from their native country to England and then about the middle of the eighteenth century Jacob Bessey came to America, settling near Doylestown, in Pennsylvania. In 1832 his grandson Adnah moved with his parents to Wayne County, Ohio, where later he married Margaret Ellenberger, of German descent, and there the son was born.

Young Bessey received his earliest education in the public schools of Ohio, and after preparing for college in the academies in Seville and Canaan he entered the Michigan State Agricultural College in Lansing where he was graduated in 1869 with the degree of Bachelor of Science, and where three years later he received a Master's degree. His intention on entering college was to become an engineer but he was advised to specialize in botany, which advice he reluctantly accepted. After much reflection, on so informing the president he was told: "Well, Bessey, I am glad of it, but you'll never be rich," and then a moment later, "Yes, I am glad of it, but you'll never be rich." After graduation he was able to study his chosen specialty at Harvard, where he was fortunate in coming under the influence of Asa Gray from whom he acquired the foundations of the knowledge of systematic botany, especially in its philosophical aspect.



Preferment in those days was naturally in the direction of teaching and in 1870 he was called to the chair of botany in the University of Iowa where he continued for fifteen years, serving also as acting president during the year 1882. He accepted a call to a similar charge in the University of Nebraska in 1884, where he has since remained, being also head of the department. During 1885-1891 he was acting chancellor of the university, and again held this high office during 1899-1900 and during 1907-1908. He was dean of the Industrial College of the University of Nebraska during 1884-1888 and again since 1895; also during 1888-1891 he was dean of the College of Literature, Science and Arts of that university.

While botany has been his favorite study it has not been his only interest; for as he says, "In Iowa I began at once to write for the agricultural papers, telling people how to plant and what to plant, telling them about weeds and grasses, telling them also about insects and their bad habits, for entomology was one of my studies at that time." He joined the Iowa State Horticultural Society and read a paper on harmful insects, and took part in the first Farmers' Institutes held in Iowa during the winter of 1870-1871. On moving to Nebraska he was equally interested and at once began to collect information on the grasses of the State, reading a paper on the subject before the Farmers' Alliance, also presenting papers before such organizations as the Fine Stockbreeders' Association, Dairy Men's Association, Beekeepers' Association, State Agricultural Association, and the State Teachers' Association.

His literary activity has been very great, for besides many contributions to technical journals and papers read before scientific organizations he was for years botanical editor of the *American Naturalist* and has held a similar relation to *Science*. He was the editor of the botanical contributions, most of which he wrote himself, that appeared in the later editions of the New Universal Cyclopedia. Also he edited McNab's "Morphology, Physiology, and Classification of Plants" (1881). His principal works in book form are: Geography of Iowa (1876), Botany for High Schools and Colleges (1880); The Essentials of Botany (1884); Elementary Botanical Exercises (1892), Elementary Botany (1904); Plant Migration Studies (1905); and Synopsis of Plant Phyla (1907).

In honors, he has received elections to the Phi Beta Kappa and Sigma Xi societies, organizations in which membership is restricted to those who have done something. The degree of Ph.D. was conferred on him by the University of Iowa in 1878 and that of LL.D from Iowa College in 1898. It may also be mentioned that he is a trustee of Doane College and he is a member of the Schoolmasters' Club.

Prof. Bessey is a member of many scientific and educational societies, as shown by the following list of organizations, in all of which he has been a prominent officer. He is a life member of the Botanical Society of America and was its president in 1896-1897; also he is a member of the National Educational Association, serving it as vice-president in 1896; and he is a member of the American Microscopical Society, of which he was president in 1902. His connection with the American Association for the Advancement of Science began with his election to membership at the Dubuque meeting in 1872. He was advanced to the grade of fellow in 1880, and has served the Section of Botany as chairman with the rank of vice-president, at the meetings held in 1890, 1902, and 1908. His long and valued connection with this foremost scientific organization in the United States gained for him the well deserved recognition of an election to its presidency at the meeting held in Minneapolis last December.

PROF. CHARLES E. BESSEY

President of the American Association for the Advancement of Science.

Opinions and Beliefs in Science

AS scientific experiments cannot be reproduced, authority necessarily remains our principal guide. In a remarkable book which bears the title "Opinions and Beliefs," the well-known French scientist, Gustav Le Bon shows how large a part mere hearsay plays in scientific investigation. A scientist never publishes results which he does not suppose to be exact, but the influence of suggestion is so strong that even regarding very precise facts, an intelligent person may come under an illusion and take the visions of his imagination for realities. One of the most striking of this kind is the mischance to which nearly all of the members of the Academy of Sciences were victims about forty years ago. On the faith of an eminent mathematician, the assembly inserted in its proceedings about a hundred letters supposed to be written by Newton, Pascal, Galileo, and others. These had been made entirely by a forger of little education and were full of vulgarities and errors, but the names of their celebrated authors and of the scientist who presented them caused them to be accepted. Most of the members had no doubts about their authenticity up to the day when the forger avowed his fraud. When the prestige had vanished, the style of the letters was pronounced wretched by the same persons who before had praised them highly.

The recent adventure of the N-rays is even more typical, and brings out not only the rôle of prestige, but also of suggestion and mental contagion. Heretofore we have to do not merely with experiments which are taken as faith by those who have no opportunity to verify them, but also with observations declared to be exact by a very large body of scientists who claimed to have repeated them. M. Blondlot, a leading professor of physics, observed, as he thought, that many bodies gave out special rays, which he called N-rays. These were detected mainly by their action on phosphorescence. Their wave-length could be measured very closely. What is most singular is that most of the French scientists working in this field repeated his experiments and saw exactly what was suggested to them to see. For two years the Academy proceedings were full of reports from scientists such as J. Becquerel, Broca, and Bichat on the wonderful properties of the rays, and Prof. D'Arsonval, among others, delivered lectures upon them. The French Academy wished to recompense such an important discovery, and delegated a committee headed by M. Mascart to make an official examination of the author's researches. The committee were much impressed, and thus a prize of $10,000 was awarded to the author.

During this time, however, foreign scientists who did not come under the prestige of the French savants, tried in vain to repeat the experiments. Then several of them decided to go to the author's laboratory to observe them. They soon found that he was the victim of a most complete illusion, for he would continue to make measurements of the supposed deflections of the rays, even when the "deflecting" was surreptitiously removed. The matter was carefully examined by a number of scientists, with the result that the specter of the N-rays was laid, once for all.

A few years ago an assistant in Prof. Lippmann's laboratory at Paris claimed to have discovered that an electrified body in movement did not deflect the magnetic needle (contrary to Rowland's experiment), a result which would have been of the highest importance for the theory of electricity. The author was not well known, but as the work was done in the presence of Prof. Lippmann, he had the benefit of his authority, and the question was discussed by physicists until a foreign scientist proved that the conclusions were erroneous and showed the reason why. In the case of the exact sciences the truth comes out sooner or later, as we have to do with real measurements and close observation. It is not the same, however, for sciences which are in a less developed stage, such as medicine; here it is very difficult to verify results, for we do not know what effects are to be attributed to suggestion or to the remedy itself, so that the errors persist for a much longer time. To enumerate them would be to go over all the history of medicine and show that theories, remedies and reasoning change every quarter of a century. About fifty years ago, the treatment of pneumonia by blood-letting was considered in France as one of the fine conquests of medical art, and its value appeared to be proved by statistics, which showed a mortality reduced to 30 per cent. Then the remedy held its place until a doctor who visited a homeopathic hospital at London found that the mortality there did not exceed 5 per cent. This was a revelation. Instead of using diluted remedies, none at all were used, and soon the mortality in France fell to the same figure. To-day, instead of weakening the patient by blood-letting, he is strengthened by alcohol stimulants. This is a good example of the change in expert opinion. There is no need to multiply the examples, and it seems evident that the greater part of our scientific opinions should not be termed knowledge, but rather belief.

A Laboratory for Manufacturers

A German Scientific Institution That Tests a Manufacturer's Raw Material and Products and Gives Him Scientific Advice

By Waldemar Kaempffert

THIS is the first of a series of articles intended to show the part that science plays in German industry and commerce. The author of the article, Managing Editor of the SCIENTIFIC AMERICAN, *was sent to Europe by the publishers to study German industrial conditions with this object in view.*

A Saxon manufacturer of silk cravats found that his orders were steadily diminishing, although the season and the market were both in his favor. He made an investigation and discovered that his customers were buying silk cravats from a Prussian manufacturer at a price fifty per cent less than that at which he could produce them. To the Saxon's eye and touch the cheaper cravats were as good as his own. He could detect nothing in the material that could explain why cravats exactly the same in appearance should be sold at two widely different prices. He spent a month in thoroughly overhauling his factory. He found that he was buying his raw material at the lowest possible prices, that his wages were not higher than they should be; that his overhead charges were not excessive, and that his organization was good. Yet the fact remained that the Prussian was underselling him and was apparently making money.

The Saxon was an expert in cravats—at least he thought he knew all about them, because he had been making them for the better part of his career. Yet for the life of him he could not explain why it was impossible for him to compete with the Prussian. One day a salesman of his suggested that it might be well to have the Saxon and the Prussian cravats scientifically compared by the Koenigliches Material-Pruefungsamt—the Royal Laboratory for Testing Materials at Gross Lichterfelde, near Berlin. The examination would cost but little and might explain the mystery. As a manufacturer, the Saxon was convinced that he knew more about cravats than any scientist in any government testing laboratory, and that his trained eye and his sensitive thumb were more to be relied upon than lenses and chemicals. Still he consented. Samples of the Prussian and Saxon cravats were sent to Gross Lichterfelde. Two weeks later he received a formal report. His own cravats were pure silk. The Prussian's cravats were half genuine silk and half artificial silk (nitro cellulose). A chemist and a microscopist, neither of whom had ever made a cravat in his life, had not only discovered in an hour or two a deception that a manufacturing experience of thirty years had failed to note, but even revealed what particular process had been used in making the artificial silk employed.

The Technical Problems of Commerce.

It would not be difficult to relate a hundred instances such as this, all of them typical of the work done at the most remarkable testing laboratory in the world. At Gross Lichterfelde I saw not only cravats undergoing a rigorous scientific investigation, but chains, girders, paper, textiles, wood, dyes, copper, rubber, ink, typewriter ribbons—almost every kind of material that is used in our daily lives. Sometimes, as in the case of the Saxon manufacturer of cravats, the manufacturer was puzzled by a rival's success; sometimes he found himself with oxidized metal or faded goods on his hands, unable to discover the cause of the defects; sometimes he thought the customs officers had wrongly appraised his importations, because they had misjudged the character of the material; sometimes he wanted to know which of several raw materials should be employed for a specific purpose and was unable to decide himself.

The Royal Laboratory for Testing Materials works hand in hand with the German industrial. For a sum of money that must seem slight to Americans it places at his command a staff of two hundred and twenty-two men, seventy-two of whom are technically trained and the highest authorities in their respective departments of science. These men have at their disposal an equipment that includes the best obtainable apparatus for testing and analysing any given material.

In Germany, indeed in Europe, the Laboratory is regarded as a court of last resort in matters involving the application of science to business. It is frequently difficult for a scientific man in the employ of a large corporation to deliver an absolutely impartial opinion on his firm's product. Inevitably there is a tendency to underestimate the products of a rival manufacturer and to view his own with favor. There is no such tendency in the Royal Testing Laboratory. There, likewise, every engineer, every microscopist, every physicist, is a government official, and, as such, he is enabled to assume an absolutely impartial and judicial attitude toward the problem given him for solution. Indeed, impartiality is insisted upon, not only in the testing and examination of materials, but also in the phrasing of the reports submitted to an applicant for information. The manufacturer who can use one of the Royal Testing Laboratory's colorless opinions for advertising purposes would be miraculously ingenious. To restrain him, however, from exercising too freely what average ingenuity Nature has endowed him, and to prevent him from quoting with approval a report which is many years old and not at all applicable to his present goods, the Director of the Laboratory refuses to furnish certified copies of opinions more than one year old, and sometimes goes to the trouble of checking up advertisements in which reference is made to the favorable opinion of the Royal Testing Laboratory.

Scientists Who Study Factory Methods in Factories.

In order that the Laboratory may keep in close touch with industrial developments, members of its staff are sent from time to time to factories in order to study the exact manner in which textiles, cement, paper, ink, and the like are made. Thus, when it was decided to elaborate the equipment for testing caoutchouc and electric insulators, the exact manner in which rubber goods are made industrially was carefully studied, so that machinery could be designed which would enable a chemist or physicist to determine those facts which would be most useful to a rubber manufacturer. What manufacturer, for example, can tell definitely whether or not rubber goods should be stored in moist or dry rooms; whether that room may be indifferently hot or cold, dark or light; whether a rubber strip should be stored stretched or unstretched? These and similar questions Gross Lichterfelde will soon answer for him definitely, as the result of a long series of most practical experiments.

German manufacturers have not been slow to recognize the immense value of a government laboratory which solves for them the technical problems of commerce. A number of manufacturers of electric insulating materials jointly supplied the necessary funds for a painstaking study of insulating materials and of the insulating properties of rubber substitutes. The many compositions submitted were tested at various temperatures to determine their readiness of manipulation in the factory, their behavior under tension, torsion, and traction; their hardness; their ability to withstand exposure to weather and chemical corrosives. When the results of these studies are published the Society of German Electro-Technicians will frame specifications for electric insulating materials, in which for the first time some admirable substitutes for rubber will receive their due.

How very impartial is the attitude assumed by the Laboratory is apparent when it is considered that manufacturers of competing materials may appeal for scientific information to Gross Lichterfelde at the same time. Sand-lime brick and clay brick are competitive building materials. Yet a powerful association of sand-lime brick manufacturers and an equally powerful association of clay brick manufacturers simultaneously consulted Gross Lichterfelde for the purpose of improving their respective bricks. The comparative tests which were made proved immensely valuable to both associations and gave the ultimate consumer a far better building material than he would otherwise have been able to purchase.

Perhaps the Laboratory has done its most efficient work in co-operation with the technical associations of Germany—associations of engineers, manufacturers and technical men. Thus in conjunction with the Society of German Cement Manufacturers, the Laboratory conducted an exhaustive investigation which has resulted in a scientific standardization of Portland cement, and has definitely settled such nice points as the influence of high temperature on concrete, the effect of copper, lead and zinc on cement, and the comparative merits of Portland cement and iron slag Portland cement. Similarly, in co-operation with the Society of German Bridge and Structural Iron Builders, a painstaking study of the strength of rivets in steel girders was made.

A Study of Paper and Ink.

It must not be supposed that all German manufacturers have been broad-minded enough to submit their products to Gross Lichterfelde for approval. An attempt to analyze the various kinds of automobile gasoline sold throughout the German Empire and to induce the wholesale dealers in gasoline to standardize liquid fuel so that the motor car owner could buy gasoline in Southern Germany exactly similar in quality to that sold in Northern Germany, was met by a flat refusal on the part of the dealers to assist the Laboratory. It is only a question of time when the Laboratory will succeed in carrying out its plan. Similar opposition was encountered when Gross Lichterfelde was commissioned by the government to analyze German papers and to determine their availability for bank notes, public documents and the like; an opposition that may be understood when it was discovered that only a very small percentage of German papers were found to answer the government's requirements. As the result of the work done at Gross Lichterfelde the German paper manufacturer has so far improved his product that rarely indeed has he failed to fulfill government conditions. Opposition to the scientific investigations of the Laboratory has given place to the heartiest co-operation.

It was but natural that after paper was studied for the government the thousand and one inks sold in the German market should have been carefully analyzed and tested to determine their chemical composition and their ability to withstand light, fire, and weather. That investigation has only recently been completed. The government can now specify with scientific precision the characteristics of a wellnigh perfect ink to be used on its wellnigh perfect paper.

The standardization of manufactures is thus undertaken only for the government. The Laboratory as a government institution entrusted with the scientific examination of material used by the government can dictate the requirements which that material must fulfill, but it would not set up standards for the manufacture of articles for ordinary consumption. When a manufacturer requested the Laboratory to determine for him the qualifications that an asphalt should have for insulating purposes, he was told that the asphalt industry must frame its own standards but that the Laboratory would assist him by giving scientific advice.

A Scientific Court of Last Resort in Technical Disputes.

As an impartial institution for scientifically passing upon the commercial availability of manufactured products, Gross Lichterfelde is required by law when requested to do so, to settle technical disputes. Instead of wasting time and money in asking the courts to decide whether or not a contract has been carried out according to the spirit and the letter, the disputants often submit their case voluntarily to the Laboratory for decision. A builder ordered a large quantity of roofing tiles and specified that they were to be waterproof. When the tiles were delivered he refused to pay for them on the ground that they failed to comply with the conditions of the contract. The dispute was submitted to the Laboratory for decision. The tiles were tested and it was found that they were sufficiently waterproof to come within the meaning of the contract.

Even if a case does go to court, the Laboratory may be asked by the presiding judge to decide the technical point at issue. The decision is binding upon both sides—a veritable boon to a court confronted with a mass of conflicting expert testimony. In one case it appeared that in the construction of a wall a stone composed of crushed slag had been employed together with lime mortar. The mortar failed to harden. The dealer who had delivered the slag stone insisted that the wrong kind of mortar had been employed. The mortar maker retorted that the slag stone was worthless. The experts summoned by both sides failing to agree as might be supposed, the court submitted the whole matter to Gross Lichterfelde. There it was decided that the mortar had failed to harden, not because it had been made with the wrong kind of sand (as one expert had declared) nor because the slag was of the wrong kind (as another expert had insisted), but because many lime mortars harden only when exposed to the air, and then only after they have been alternately moistened and dried. Hence, said Gross Lichterfelde, the core of a wall, as in the case in question is not likely to harden at all, whether or not a slag stone or good brick is employed.

In another case the court called upon the Laboratory

The Heavens in January

Constellations of Southern Skies

By Henry Norris Russell, Ph.D.

THE star-maps published every month in the SCIENTIFIC AMERICAN represent the sky as it appears to an observer in the latitude of New York (approximately 40 degrees north) and consequently fail to show the stars within 40 degrees of the south celestial pole, which are visible only in lower latitudes.

To meet the needs of observers in the southern part of the United States or in more southern countries the accompanying map has been prepared showing all the stars clearly visible to the naked eye within 60 degrees of the south pole.

The whole region of the heavens here represented can be seen at once only from points in extreme southern latitudes. From stations north of the equator less than half of it is visible at any one time. It is, however, very easy to adjust the map so as to show just what southern stars are in sight from any given station, at any day and hour.

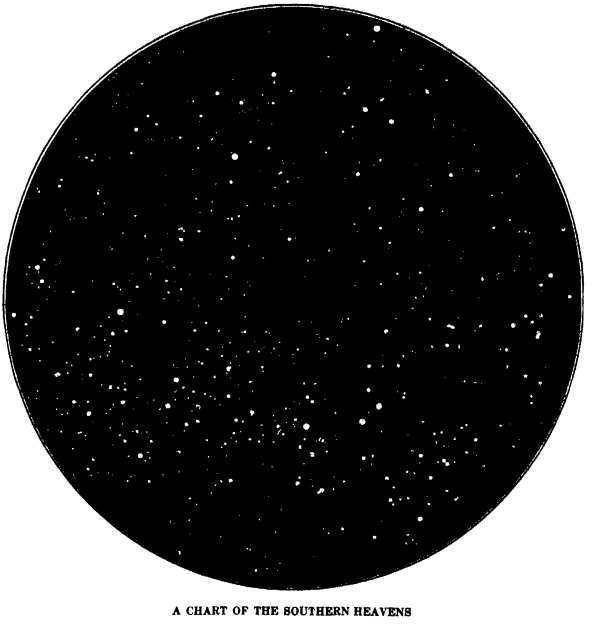
We need only know the observer's latitude (which can be obtained with sufficient accuracy from any good atlas) and the sidereal time. The latter can be found closely enough for our purpose by adding together three numbers: 1, the local time as given by an ordinary clock; 2, the quantity given in the accompanying table for the current month; 3, four minutes for each day of the month to date.

	h	m
January	18	20
February	20	44
March	22	32
April	0	34
May	2	32
June	4	34
July	6	31
August	8	35
September	10	37
October	12	35
November	14	38
December	16	36

Midnight should be counted as 12 hours, 1 A. M. as 13 hours, and so on, and if the sum exceeds 24 hours, this amount should be subtracted from it. For example, for 1 15 A. M. on October 25th, we have:

	h	m.
Clock time	13	15
From table, for October	12	35
4 × 25 = 100 minutes, or	1	40
Sum	27	30
Subtract 24 hours	24	0
Sidereal time	3	30

The results of this calculation will be correct within four or five minutes at the most if the observer's clock keeps local time. If it keeps standard time, the result should be corrected by the amount by which standard time is fast or slow of local time. For our present purpose, this correction is usually hardly necessary.



Find now the point on the margin of the map corresponding to the sidereal time, by means of the scale of hours and minutes on the edge, and turn the map till this point is at the top. Then lay a straight edge across it so that it passes above the center at a distance equal to the observer's latitude (if north of the equator). As the white circles on the map are 10 degrees, 20 degrees, 30 degrees, etc. from the center, this can be done very easily. The part of the map above the straight edge then represents the southern sky, as it appears above the observer's horizon. In strict accuracy, the line representing the horizon should be curved, so as to be about one-third nearer the horizontal diameter of the map at the edges than at the center; but this too is of small practical importance.

For stations south of the equator, where the south celestial pole is above the horizon, the straight edge should be held below the center of the map, at a distance equal to the latitude. Stars in other parts of the sky than the south may be identified by the aid of the maps published every month. The present map is purposely made to overlap the southern portions of those by about twenty degrees, to facilitate passing from one to the other.

The familiar aspect of the northern heavens on a winter evening needs little description.

Orion and Canis Major blaze in the south, with Argo on the horizon below them. Gemini and Canis Minor are east and southeast of the zenith, Auriga directly overhead, and Taurus southwest of him. The planets Mars and Saturn, near together, between Taurus and Aries, increase the brightness of what is at all times the most brilliant region of the starry sphere.

Hydra, Leo, and Ursa Major are conspicuous in the eastern skies; Draco, Ursa Minor, and Cassiopeia in the north, and Perseus and Andromeda in the northwest. The only really dull region is in the southwest, which is filled rather than illumined by Pisces, Cetus, and Eridanus.

A CHART OF THE SOUTHERN HEAVENS

The Planets.

Mercury is morning star all through January. He is best seen about the 15th, when he is nearly 24 degrees from the sun. Being far south of the equator, in Sagittarius, he rises relatively late, about 5.45 A. M., but he can be readily seen, before dawn, appearing as a star about as bright as Vega. Venus is likewise morning star in Scorpio, rising about 4 30 A. M. in the middle of the month. Jupiter is a morning star, too, in the same region of the sky. On the 9th the two planets are in conjunction. Venus, which is about 1½ degrees north of Jupiter, appears about eight times as bright to the eye as he does, but in the telescope shows a disk little more than half as big. This very great difference in the apparent brightness of the surfaces of the two planets does not arise from differences in their reflecting power, but from the fact that Venus being relatively near the sun receives about fifty times the strength of sunlight that Jupiter does.

Mars is in Taurus, not very far from the Pleiades, and comes to the meridian at 8 P. M. in the middle of the month. He is rapidly receding from the earth, being 65,000,000 miles away on the 1st, and 88,000,000 on the 31st, and in consequence he diminishes steadily in brightness. At the beginning of the year he is two as bright as Arcturus, and excelled only by Sirius, but at its end he is hardly equal to Capella.

Saturn is in Aries, about 10 degrees west of Mars, and appears about as bright as Procyon. His distance from the earth is so great—over 800,000,000 miles—that the forty millions by which it increases during the month makes but a small percentage of change in his apparent size and brightness.

Uranus is in conjunction with the sun on the 20th, and is invisible throughout the month. Neptune is in opposition on the 13th, and is well observable throughout the month. His exact position may be found at any time by interpolation between the two places:

	h m s.	deg. m.
Dec. 31..	7 37 58	+ 20 57.2
Feb 1 .	7 34 13	+ 21 6.2

This puts him very near the line drawn from β Geminorum to a point found by carrying a line from β Geminorum through κ, and as far again. He appears as a star of magnitude 7.6, and can only be seen with telescopic aid.

The Moon is full at 7 A. M. on the 4th, in her last quarter at 2 A. M. on the 11th, new at 5 A. M. on the 19th, and in her first quarter at 3 A. M. on the 27th. She is nearest us on the 4th, and farthest away on the 17th. As the full Moon comes almost exactly at the time of perigee, we may expect unusually high—and low—tides on and about the 4th.

The Moon is in conjunction with Mars on the morning of New Year's Day, and an occultation is visible, in the morning hours, from points in the southwestern portion of the United States. She is also in conjunction with Neptune on the 4th, Jupiter and Venus on the 15th, Mercury on the 17th, Uranus on the 19th, Saturn on the 27th, and Mars again on the 28th, when a second occultation may be seen in the extreme north of this country.

A comet, visible in a small telescope, was discovered by the French astronomer Schaumasse on November 30th. It is moving slowly eastward through the northern part of Virgo, and increasing in brightness. On January 1st it will be in about 15 hours 15 minutes R. A. and 2 degrees south declination, moving about 1 degree east and 15 minutes south per day.

The first calculation of its orbit (by the discoverer and an associate) shows that it is still approaching the sun, and will not reach perihelion till February 5th, at which date it will be 108 million miles from the sun, and rather more distant from the earth. It will never be very near us, and in consequence may not be at all conspicuous; but it will be observable in the morning sky for some three months to come.

Princeton University Observatory.

Largest University in the World

REGISTRATION, now complete at Columbia University, shows that the attendance upon the university courses for the scholastic year is 7,468 as compared with 6,842 last year, an increase of 626, and, including the extension courses, the number is only eight short of 8,000. This places Columbia at the head of all other universities in the world in point of attendance, taking the place of Berlin, which stood at the head last year.

Progress of Work on the Panama Canal

Prospects of Completion by July 1st, 1913

THE original estimated date for the completion of the Panama Canal was January 1st, 1915. The work has advanced so rapidly that it has become apparent that the canal can be used at least a year earlier than this date. In order to determine the approximate time when shipping could pass through, a board was convened during the past year, composed of those charged with the work in progress and contemplated. Announcement was made that concreting of the locks at Gatun would be finished by June 1st, 1912, and the locks on the Pacific side four months later. Assuming that the gates were completed by June 1st, 1913, the contract time, the locks would be ready on that date, if the operating machinery were installed. The Gatun dam, it was estimated, would be finished by the close of the dry season 1912-1913, and if no more material, due to slides, had to be removed than was estimated at the time the board met, it was decided that the Culebra cut would be completed by July 1st, 1913. The exterior channels leading to the canal from the two oceans, it was found, would be sufficiently advanced to pass such shipping that would use the canal, by this same date, July 1st, 1913.

The report of Col. George W. Goethals, chairman and chief engineer, shows that progress during the past year has been eminently satisfactory. At Gatun locks, by the end of the fiscal year, the skeletons of four leaves of the gates were in position for a height of four panels, and those on the east chamber were completely riveted. At all of the locks, fender chains are to be placed 500 feet above and 230 feet below the upper and lower guard gates. When in use, they will be raised to the surface of the water, forming a barrier to the passage of ships. When it is struck by a vessel, the chain pays out against a resistance provided by hydraulic cylinders. The energy of a 10,000-ton ship moving four miles an hour will be absorbed after it strikes the chain before it reaches the gate.

Contracts for emergency or movable dams to check the outflow of water should the gates be carried away, have been awarded for $2,238,968, and all of these dams are to be completed by June 15th, 1913. Studies are being made of an electrical plant for operating the canal after completion, which contemplates a hydro-electric station on the Gatun dam, and a steam reserve generating station at the Miraflores locks.

A scheme for lighting the canal has been adopted. It contemplates the use of range lights for establishing the direction on the longer tangents, and of side lights, spaced about a mile apart, to mark each side of the channel. The project calls for the construction of 34 tower beacons of reinforced concrete, 57 beacons, 57 gas buoys, 76 spar buoys, and 7 nun buoys. There will be two parallel sailing lines marked by range lights, which will be 250 feet apart, so that two passing ships, if on their ranges, will be 250 feet apart, center to center of ships.

Atlantic Division.

At the Gatun locks the excavation has been completed, except for a small amount at the north end of the lower locks. The concreting plant has shown great efficiency and capacity. The unloading cables have handled 500,550 cubic yards of crushed stone, and 241,858 cubic yards of sand. During the year, 945,525 barrels of cement were received into the storehouse, and in the same time an average of 6.08 of the eight 2-yard mixers furnished a total of 602,851 cubic yards of concrete. The total amount of masonry laid by the construction plant and by hand at the Gatun locks aggregated 911,137 cubic yards—a rate of 260.6 cubic yards per hour of service. The cost of the masonry was $6.64 per cubic yard. At the close of the year the masonry for the Gatun locks was 68.84 per cent completed. Over half a million cubic yards of backfilling was placed in the rear of the side walls of all the locks. A total of 31,060 feet of concrete piling was constructed for the foundation of the south middle approach wall, leading to the locks from Gatun Lake.

A total amount of 864,033 cubic yards of stone was crushed at the Porto Bello quarry at an average cost of 1.38 cents per yard, and from Nombre de Dios a total amount of 441,919 cubic yards of sand was obtained and transported in barges to Gatun, where it was transferred to the stock pile, at a cost, in the stock piles, of 1.86 cents per cubic yard.

Gatun Dam.

The Gatun dam has been formed by building two large rock embankments, and filling in the intervening space by hydraulic sluicing. During the year, on the east portion of the dam, the embankments have been raised from 65 feet to 85 feet above mean tide, and the hydraulic fill has been raised from 51 to 73 feet. On the west portion of the dam, the dry fill has been raised from 35 to 67 feet, and the hydraulic fill from 16 to 57.3 feet. The total increase of material, dry and wet, during the year has been 5,819,056 cubic yards. The cost of this work has been 38 cents for dry fill, and 23 cents for wet fill. The material for dry fill was brought by railway from Culebra cut, from the lock site, from Mindi, and from the spillway. The hydraulic fill was obtained from above and below the dam, and was placed by five suction dredges. The dam at the close of the fiscal year was 74 per cent completed.

Work on the spillway has proceeded very satisfactorily, and the concrete portion of the work is 66 per cent completed.

The channel between Gatun locks and the Atlantic is being attacked at several points, and 423,427 cubic yards have been removed between the locks and the Mindi hills. From the excavation through the Mindi hills 401,511 cubic yards have been removed by hydraulic dredge, and 280,000 cubic yards of earth and rock have been taken out by steam shovel. Between the Mindi hills and deep water in the Caribbean, the sea-going dredge "Caribbean," two dipper dredges, and three French ladder dredges have removed 4,516,369 cubic yards of earth and 487,038 cubic yards of rock, at a cost of 22 cents per cubic yard. The breakwater leading out from Toro Point has been pushed forward until, at the close of the year, 5,365 feet of double-track trestle had been completed, and 359,800 cubic yards of fill had been dumped from the trestle.

Central Division—Culebra Cut.

In the central division, the most important construction district is, of course, the great Culebra cut, from which during the fiscal year over sixteen million cubic yards were excavated, leaving, according to estimates of July 1st, 1911, about twenty-four million cubic yards yet to be taken out. The amount remaining has been increased during the year by 4,076,000 cubic yards, this to allow for the enormous slides which have developed, in the removal of which alone during the year, 4,880,000 cubic yards has had to be handled, which is over 30 per cent of the total amount removed from the cut during the year. The magnitude of this problem may be judged from the fact that thus far 10,757,000 cubic yards have been removed from slides, and the estimated amount remaining is nearly six million cubic yards. Col. Goethals states that slides follow the excavation in places where the material is left at a steeper slope than it will assume in its natural state; in which case it sloughs off until the natural slope is reached, and the movement ceases. Experience shows that it is only a question of time when these slides will cease entirely. Six of the good-sized slides are now quiet, and there is less trouble generally from this cause than at any time since the slides began to move.

A gratifying feature of this problem is the fact that, in spite of the enormous increase of 15,000,000 cubic yards of excavation due to slides, the reduction in unit cost, due to the splendid efficiency of the organization, will wipe out the extra cost of the slides, leaving the original estimate of excavating Culebra sufficient to cover the total cost of the work.

The average cost for excavation for the year was 59 cents per cubic yard, and at the close of the year the Culebra cut was 73.75 per cent completed.

Pacific Division.

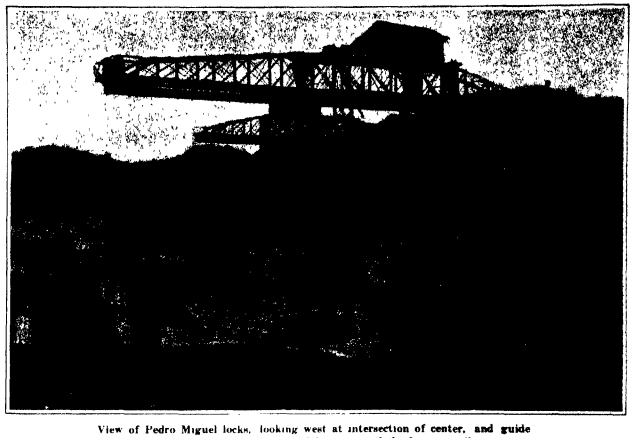
The work of this division consists of the construction of the locks and dams at Pedro Miguel and at Miraflores, and the excavating of a channel between the locks, and from Miraflores locks to deep water in the Pacific. The total amount of concrete laid in the Pedro Miguel locks at the close of the year was 665,056 cubic yards, and the lock was 79.43 per cent completed. The locks at Miraflores, so far as the concrete work is concerned, are 19.27 per cent completed. As regards the channel between the locks and the Pacific Ocean, work has advanced satisfactorily between the two locks, and operations are being vigorously pushed upon the section lying between Miraflores locks and the Pacific Ocean. The dredges operating in the channel during the year were the 20-inch suction sea-going dredge Culebra, one dipper dredge, and three French ladder dredges. They removed from the channel a total of five and a half million cubic yards at a cost of 25 cents per yard, leaving a total of 4,700,000 cubic yards to be removed, including an estimate for slitage.

Towing Locomotives for the Gatun Locks.

By studying our front page engraving, it is possible to get a very accurate impression of the Gatun dam, with its spillway through the center, and of the massive concrete locks, through which access will be had to the Gatun Lake. The Gatun locks will be double, one set for ascending and the other for descending vessels. They will be in three flights, and will have a total lift of 85 feet—this being the difference between the level of the surface of the lake and mean tide level of the Atlantic at this point. The locks lie some six miles from the Atlantic shore line, and the channel will be tidal up to the lower lock gates, with a small rise and fall of two feet—one above and one below mean level. (At the Pacific end, the rise and fall is 11 feet above and 11 feet below mean tide level.) The locks are the largest ever constructed, each having a width of 110 feet and a usable length of 1,000 feet. Entering the canal from the lake ships will find themselves guarded against running into the locks by fender chains which normally will lie at the bottom of the locks, but when a ship is entering will be stretched across the surface. As a further protection to the gates, there will be guard gates, placed some distance ahead of the main gates. These gates could be wrecked by an over-running ship without destroying the integrity of the canal and letting the water out of the lake.

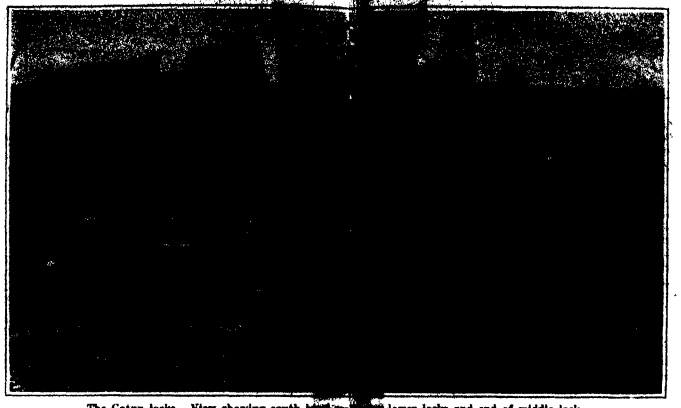
Should a big vessel, becoming unmanageable enter with such force as to carry away fender chain, guard gates, and the main gates themselves, an emergency dam is provided, by which the entrance to the locks could be closed. This dam consists of a massive swing bridge, which, in case of accident, could be turned so as to lie across the lock entrance. From the over-spanning bridge a series of massive leaves of plate steel, extending entirely across the lock prism would be lowered, gradually shutting off the flow of water, from below upward until the wall of plates extended above lake level, when the entrance would be entirely closed.

Ships will not pass through the locks under their own power. Each ship will be taken in hand by four powerful electric locomotives, one off each bow, and one off each quarter. The locomotives will each weigh 70,000 pounds. They will be driven by electric motors, operating gears which will engage a rack rail, and the hawsers from the ship will be attached to the wind lasses of the locomotives, which will be provided with friction clutches, that will prevent the drums sustaining a pull of more than 25,000 pounds. The speed of the ships, when in tow of the locomotives will be not over two miles per hour. The provision of rack rail traction, and the power and number of the locomotives, combined with careful operation, will practically eliminate any risks to the locks during the passage of vessels.



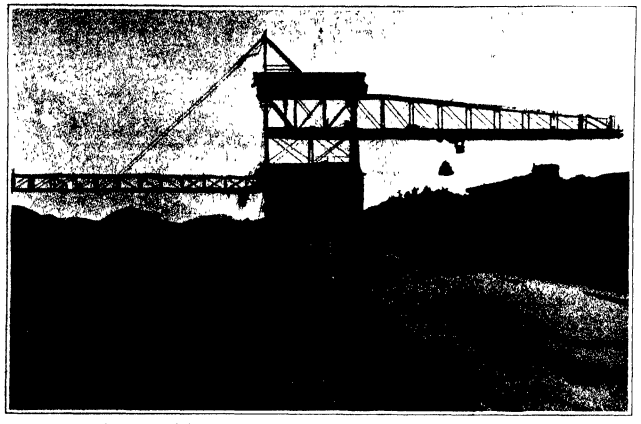
Preserve Your Papers; They Are of Permanent Value

By taking a little trouble when a paper first comes to hand, it may be preserved to form a permanent and valuable addition to the reading matter with which everyone should be supplied. We furnish a neat and attractive cloth board binder which will be sent by mail, prepaid, for $1.50. It has good strong covers, on which the name SCIENTIFIC AMERICAN or SCIENTIFIC AMERICAN SUPPLEMENT is stamped in gold and means by which the numbers may be securely held as in a bound book. One binder may thus be made serviceable for several years, and when the successive volumes, as they are completed, are bound in permanent form, the subscriber ultimately finds himself for a moderate cost, in possession of a most valuable addition to any library, embracing a wide variety of scientific and general information and timely and original illustrations. Save your papers.



To Our Subscribers

WE are at the close of another year—the sixty-seventh of the SCIENTIFIC AMERICAN'S life. Since the subscription of many a subscriber expires, it will not be amiss to call attention to the fact that the sending of the paper will be discontinued if the subscription be not renewed. In order to avoid any interruption in the receipt of the paper subscriptions should be renewed before the publication of the first issue of the new year.



To those who are not familiar with the SCIENTIFIC AMERICAN SUPPLEMENT a word may not be out of place. The SCIENTIFIC AMERICAN SUPPLEMENT contains articles too long for insertion in the SCIENTIFIC AMERICAN, as well as translations from foreign periodicals the information contained in which would otherwise be inaccessible. By taking the SCIENTIFIC AMERICAN and SUPPLEMENT the subscriber receives the benefit of a reduction in the subscription price.

A Typewriter for the Blind

IN view of the highly developed sense of touch in blind persons, the idea naturally suggests itself to construct a typewriter especially for their use, with the keys marked with the characters in raised type. A machine of this character, shown in the accompanying illustration, is the invention of M. Cayzergues, of Paris Needless to say, when the operator has

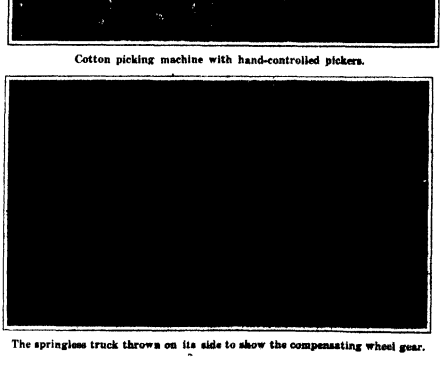
A typewriter for the blind.

become proficient, the marks upon the keys are no longer necessary, and in fact the provision of raised characters upon the keys is the least of the special features required in a machine for the blind What is needed is some arrangement whereby the operator is able to check up his work as he goes along and to correct any mistakes that may occur With this in view, the machine which has been built is a combination of two separate printing mechanisms, both operated simultaneously from the same keyboard One set of levers produces a record in raised characters on a paper cylinder, while another set at the back produces the usual written copy upon a separate sheet The copy thus obtained represents the ordinary letter form as employed for business and other purposes, while the record on the paper cylinder is made in the special character used by the blind, consisting of a combination of small dots In this way the blind writer is furnished on the one hand with a copy of his letter and on the other hand with a means for reading his writing as he goes along

The new typewriter is not very much more complicated than the usual form Each paper roller slides along a toothed rod, in such a way that every time a key is struck, both carriages move along the distance of one tooth The spacing of the lines is effected by hand by pushing a lever, so as to shift the roller carriages one space The front carriage is arranged to operate the rear carriage through a rod and gear coupling The raised record is so placed that the operator can run his fingers over it practically without interfering with his work

When desired, the special mechanism for the blind can be disconnected and either part of the machine used separately

Springless Truck for Rough Ground



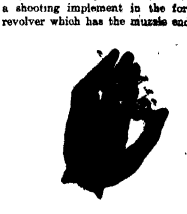
THE accompanying engraving illustrates a very novel form of vehicle, which by the use of eight wheels, dispenses with all springs, the wheels being so mounted as to enable it to travel over rough ground without being materially lifted by the obstacles over which it passes A closer examination of the engraving will reveal the construction Each wheel is mounted in a separate fork hinged to the frame above. The forks are connected in pairs by links running from crank arms on each to a common cross tree As a result, should one wheel strike an obstacle, it would swing backward to clear the construction and in so doing would draw the cross tree backward, pulling its mating wheel forward There would thus be a co-operative action between the two wheels in passing over the obstacle which would result in a practically level running of the vehicle body Such being the case, there would be no necessity for springs. Of course, the truck body would not run perfectly level, but the rise and fall would be considerably less than with a four-wheeled truck of the ordinary construction As most of the work done in drawing a vehicle consists in raising it over obstructions, it follows that the flexible wheel mounting here shown would call for much less tractive effort than is ordinarily the case.

Novel Cotton-picking Machine

THE machine which is pictured in the accompanying engraving is not completely automatic in its action It is provided with a number of pickers, each of which must be separately controlled by an operator The machine is driven by a three-horse-power kerosene engine, the entire outfit weighing about 800 pounds The pickers operate somewhat on the principle of the spiral screw-driver They consist of a shaft which rotates and at the same time has a reciprocal motion, so that it will alternately protrude and withdraw into a casing The latter movement is produced by means of a guide with a double spiral groove At the end of the shaft is a finger adapted to catch the cotton boll and twist it out of its pod, after which the picker is withdrawn within its casing, the boll is stripped from the finger and carried by means of an air blast through a cleaner that removes any leaves or sticks that may adhere thereto, and deposits the clean cotton in a bag The picking finger is operated by means of a flexible shaft, while a separate flexible tube runs to the picker to convey the cotton to the cleaner By providing individual control of the pickers, the cotton may be picked from parts of the plant which might be inaccessible to a purely mechanical machine On a test with the cotton picker illustrated, two men being employed, a hundred pounds of cotton was picked per hour.

Cotton picking machine with hand-controlled pickers.

The springless truck thrown on its side to show the compensating wheel gear.



Youngest Patentee of Record

THERE is no age limit to patentees. Take the patent, No. 465,066, of December 15th, 1891, to Donald M. Murphy, of St. John, Canada. One might think from his X mark signature to the specification that Donald could not write his name, and he could not, for he had no book learning, but he did have the inventive ability to produce a sounding toy for which the United States Patent Office granted him a patent But do not blame him for his lack of schooling, for Donald was only six years old when he filed the application, and as far as is known the youngest applicant for patent in this or any other country His picture formed a part of the Patent Office Exhibit at the Chicago Worlds' Fair in 1893 The toy patented to him is a simple contrivance including a bar with handle knobs at its ends and two clapper disks slidable along the bar so they can sound against each other and against the handle knobs. See accompanying illustration

Notes for Inventors

Death of Thomas Hall.—Thomas Hall, known for his inventions in connection with the manufacture of typewriters, died recently at the age of 77 He won a prize at the Paris Exposition of 1867, by the exhibition of a keyed typewriter Mr Hall also invented a number of sewing machine attachments and an improved drill grinder. He was born in Philadelphia, February 4th, 1834

Fire Arm for Stage Use.—Most of us cannot shoot straight with a revolver designed for straight shooting, but to make sure of this John E. Basmer, of Mt. Airy, N. C., has patented (No. 1,007,174) a shooting implement in the form of a revolver which has the muzzle end of the

Clapper invented by a six-year-old boy.

barrel closed and its bullet passage or bore deflected at its discharge upwardly and out through the top of the barrel so the bullet will pass almost vertically upward.

A Cloud Protector for Aeroplanes.—Army and navy ordnance experts are giving much time and thought to the best manner of attacking airships aloft Various guns for firing at the fliers have been invented "Is it not practicable," says one of our correspondents, "to provide some means, chemical or otherwise, by which the aviator can, at his pleasure, produce some cloud like vapor to envelope his machine and obscure it from the view of the enemy? The artificial cloud might be visible, but would only form a large target while the machine, the real objective point of the firing lines, would form only a small part of the target, decreasing in proportion to the size of the cloud the prospect of being struck by the projectiles."

Color Changing Flaming Arc Lamp.—Color effects in arc lamps are sought by a patent, No 1,007,869, to Chas. W. Hill, of Lakewood, Ohio, assignor to National Carbon Company, of Cleveland, who provides an electrode for flaming arc lamps, in different portions of which are incorporated different substances, adapted as they volatilize, to give to the arc stream a characteristic color, thus imparting a succession of color changes to the arc as the electrode is consumed

Prevents Hen from Setting.—Setting hens are proverbially persistent but Vern M. Osborn, of Los Angeles, in patent, No. 1,008,050, furnishes a poke like device which he straps on the hen showing setting proclivities, the device being provided with a pair of legs which project down in front of the hen's legs so that she cannot assume her usual posture on the eggs.

A Hewitt Vapor Converter.—Peter Cooper Hewitt of Ringwood Manor, N. J., has secured a patent, No. 1,007,694, for a vapor rectifier in which a container has a conducting receptacle with hollow arms extending from it and conducting caps, constituting the terminals of the arms and forming the main positive electrodes of the apparatus, while the negative electrode is contained in the receptacle.

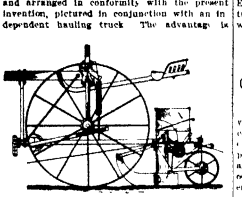
A Multi-blade Safety Razor.—A razor described in patent No. 1,007,847, granted to Axel Anselin Carlson, of Lindsborg, Kansas, has a casing and a blade guard. A carrier having a number of blades is revolubly mounted in the casing so that any one of the blades which are removably and yieldingly mounted in the casing may be brought into operative position relatively to the guard.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The items are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

DRYING AND STRETCHING FRAME.—C. WIRKLER, 1640 Amsterdam Ave., New York, N. Y. This invention relates to apparel apparatus. It provides a frame more especially designed for drying stockings quickly and in pairs to prevent misplacing of mated stockings and to prevent the stockings from shrinking, the frame also permitting of convenient adjustment to readily accommodate stockings of different sizes



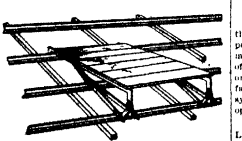
EAR MUFF.—W. H. FRENCH, Evansville, Ind. An object of this invention is to provide a strong and simple ear muff which serves efficiently to cover and protect the ear against the injurious effects of cold, wet, wind, etc., which is compact in form, and which is so constructed that it can be securely held in place without the use of a spring bow or other devices

ELECTRIC TIME SWITCH.—C. J. LINDEWALD, 312 Dean Building, South Bend, Ind. An object here is to provide a device which is controlled by clock-work, and which may be set to close a circuit at any predetermined time, and to open the same subsequently at any predetermined time. A further object is to provide a device in the nature of an improvement to an ordinary clock for accomplishing the closing and opening of the switch.

Of Interest to Farmers.

COW STANCHION.—F. A. BRUNDAGE, Box 38, Belmont, N. Y. This invention relates generally to cow stanchions, and more particularly it involves an improved form of stanchion having means whereby the movable bar in the stanchion may be locked and unlocked. The stanchion has an improved locking means whereby the movable bar may be easily and quickly brought to either operative or inoperative position

AUXILIARY PLANTER.—A. R. BALDWIN, care of Rogers and Baldwin Hardware Co., Springfield, Mo. The accompanying illustration shows a side view of a planter constructed and arranged in conformity with the present invention, pictured in conjunction with an independent hauling truck. The advantage is



AUXILIARY PLANTER

obvious, as it enables the planter to be used in conjunction with any other suitable farm implement. As an instance, it will be conceived that to attach a planter thus constructed to follow gang plows or harrows would serve to shorten the operation of preparing the field by just so much time, cost and labor as would be needed to plant the field after the bed has been prepared, as in the present custom

Of General Interest.

ADJUSTABLE BRACKET.—P. WHITE, 102 Academy Street, Long Island City, N. Y. This invention relates to a form of bracket for scaffolding, more particularly adapted for use by the setters on sloping constructions. The objects of the inventor are obtained by constructing a bracket of a general triangular shape, having an adjustable hook depending

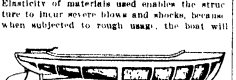
ADJUSTABLE BRACKET.

from one end to fit over a metallic framework of an unfinished roof, positioning two of these brackets apart on the roof and connecting the same by a seanting of lengths of boards to form a readily constructed bracket. The perspective view herewith shows an embodiment of the invention applied to a roof construction

COMB AND BRUSH.—W. J. HOPE, Tunica, Miss. This invention is an improvement in a comb and brush, and the aim is the provision of a simple, compact and cheaply constructed device combining the functions of both instruments, as shown in the engraving, which will be capable of being carried in the pocket, will not easily collect dirt, and which may be easily cleaned. It is handled in the same manner as an ordinary comb. As the teeth pass through the hair, the bristles smooth the hair

COMB AND BRUSH

both in front and behind the teeth. Either set of bristles may be used alone by inclining the comb, or the teeth may be used with both. Only a slight portion of the length of the teeth extends below the bristles

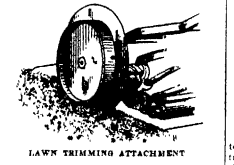


GUITAR.—A. BRATTO, 1261 Lyod Avenue, High Bridge, Bronx, N. Y. The invention relates generally to stringed musical instruments and more particularly it involves an improved construction of body of a guitar. From the engraving it will be seen that the bridge is supported entirely by the sounding board being out of contact with the top of the body,

GUITAR

this construction affording an increase in volume and an improvement in the tone of the sounds since the free vibration of the board is not interfered with in any way by the hands when playing, the vibration of the strings is transmitted directly to the sounding board and none of the energy of vibration is dissipated in through contact with the body since the bridge rests on the sounding board

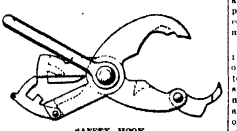
UNSINKABLE BOAT.—J. PANTOREL, P. O. Box, 947 Asbury Park, N. J. The frame is constructed of hard rubber and is covered with sheets of rubber or rubber cloth in such a way as to form independent air tight compartments, inflated to increase the boat's buoyancy. Elasticity of materials used enables the structure to incur severe blows and shocks, because when subjected to rough usage, the boat will



UNSINKABLE BOAT

yield instead of breaking as it might in case common material, such as wood or iron, were employed. The object of the inventor is to produce a vessel which will be lighter, faster and better able to resist damage than any other vessels of the same description. The engraving shows a side view of the framework

Hardware and Tools.

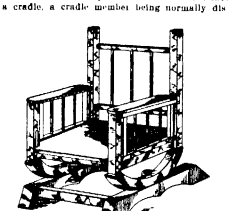


LAWN TRIMMING ATTACHMENT.—W. F. HILL, Charleston, Ill. It is the purpose in this invention to provide a lawn trimming or edging attachment of novel form and design which may be detachably secured to a wheel of an ordinary lawn mower, as pictured in

LAWN TRIMMING ATTACHMENT

the accompanying engraving, and when in position may be efficiently operated, with a minimum of time and labor required, to cut off all grass projecting outward over the edge or border of a grass plot, and to trim the face of the turf or sod in a uniform and symmetrical manner. The device may be operated by an unskilled operator.

SAFETY HOOK.—R. LANGE, care of Hugo Lange, Okanogan, Wash. This device is adapted



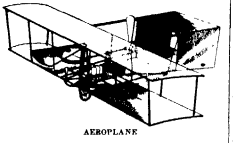
SAFETY HOOK

to carry a load of crates, or used as a harness hook or other readily-releasable connecting device suitable for carrying a load or resisting a strain. To this end the hook in general comprises two hook members pivoted together to swing to and from each other, one of the hook members having a gate adapted, when the hook members are closed and locked, to swing inwardly and permit the insertion and removal of the suspension link, the gate arranged at the mouth of the hook to take the strain on the link. The illustration shows the hook members released and swung apart

Household Utilities.

BROILER.—J. W. TAYLOR, Box 93, Antigonishe, Nova Scotia, Canada. In this patent the invention has reference generally to broilers and more particularly it relates to those articles of this class which comprise a pair of extended body portions suitably hinged together and between which articles of food are held over the fire in order to be cooked and held in a manner that will not permit the food falling out

CONVERTIBLE CHAIR.—A. DEMERS, 461 Granite Street, Manchester, N. H. This invention has reference to convertible chairs and it has for its purpose the provision of a rocking chair which may be readily converted into a cradle, a cradle member being normally dis-



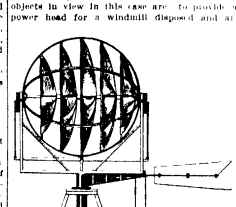
CONVERTIBLE CHAIR

posed under the seat of the chair which may be erected across the front of the chair to form the side member for the cradle, the sides of the chair being adjustably mounted so that they may be lowered to a horizontal position to form the head and the foot of the cradle. The chair is pictured in perspective in the accompanying illustration

Machines and Mechanical Devices.

CHECK PROTECTOR.—C. H. SAMPSON, Rochester, N. Y. This invention refers to protectors employed for providing a check with a mark pressed into the paper and representing a certain sum and the words "Not over." It provides a protector arranged to permit the user to view the line of the check where the printing is to take place and to provide a single hand lever mechanism for controlling the movement of the printing parts

AEROPLANE.—G. W. THOMPSON, Kingston, Okla. This invention relates to flying machines of the heavier than air type and the object is to provide a machine of this class which has its propellers so arranged that they not only drive the machine but steer it also. By such a construction the inventor minimizes the necessity of using movable rudders here-



AEROPLANE

tofore used to control the machine's course of travel. Balancing is accomplished by locating the power plant directly below the center of gravity of the supporting planes, and by the manner in which the planes are tilted with reference to the line of travel. The improved aeroplane is shown in perspective in the accompanying view

FLYING MACHINE.—R. COLE, Norwalk, Ohio. This improvement relates to a flying machine, and particularly to aeroplanes in which an automatic balance of the equilibrium is obtained. A further object is to provide a flexible connection between the main supporting plane and the frame, whereby the equilibrium of the aeroplane is automatically maintained

FLUID PRESSURE TOOL.—A. C. MCFARLANE, 601 North Wabasch, Colo. The object of this invention is to provide a fluid pressure tool, arranged for running the tool at a high speed and with economy in the use of the motive agent, to reduce jar and vibration to a minimum and to prevent breaking of the operating parts, especially when the tool is running without the drill being in place.

WINDMILL.—C. F. CRADDICK, 514 W. Porphyry St., Butte, Mont. The accompanying engraving shows a side elevation of a windmill constructed and arranged in accordance with the present invention. The principle objects in view in this case are: to provide a power head for a windmill disposed and arranged as a series of turbine shape rotating members, provides a power head having a maximum wind pressure surface disposed in power relation to the wind and having the maximum of exposed surface when disposed in angular relation to the wind and to provide regulating means for automatically varying the pressure under operative conditions

WINDMILL

Prime Movers and Their Accessories.

ELASTIC FLUID TURBINE.—R. HARRISON, 58 Chancery Lane, London, England. In this patent the invention has for its purpose the production of an efficient turbine of simple and strong construction having the steam nozzles, exhaust openings and connecting channels so arranged that the work to be done by the steam shall be distributed over two or more stages arranged around the circumference of a single rotor

CARBURETER.—W. A. HARRIS, 237 John St., Greenville, S. C. The invention in this case is an improvement in carburetors and the purpose of the inventor is the production of a carburetor of the character specified for use in vaporizing gasoline and mixing air therewith in the most favorable proportions for the most efficient combustion

Railways and Their Accessories.

RAILROAD TIE SPACER.—J. W. WOOD, Nicolas, Cal. In the present patent the invention is a spacer for railroad ties, and it comprises a device which can be readily placed in position to grip the top of a rail and which acts as a fulcrum for the spacing bar which is used to force the tie into proper position

BRAKE BEAM AND FULCRUM THEREFOR.—J. B. SIMPSON, Paxton, Pa. This improvement relates to brake beams and fulcrums therefor, and it has for its object to provide a fulcrum member having means by which it may be conveniently secured to a U-shaped or other beam without slipping, the fulcrum over the end of the beam and without splitting the fulcrum member

Pertaining to Recreation.

TRAVELING ROCKING HORSE.—W. ROGERS, 762 W. Mulberry St., Springfield, Ohio. This improvement has reference to traveling rocking horses and the object is to provide one which is propelled by means connected to a rock shaft to which the horse is secured, stimulating means provided which, in connection with steering mechanism by which the direction of travel may be controlled

Pertaining to Vehicles.

VEHICLE TIRE.—F. TAUMAN, Morley, Iowa. The invention provides a resilient tire constructed of spring metal to avoid disadvantages in the employment of rubber tires of usual construction, provides a tire constructed from a series of sectional forms each detachable and replaceable, provides an articulated tire of metallic sectional springs each cooperatively connected with adjacent springs to unite the action of the springs, provides a tire with stop members to reinforce the tire structure to avoid the breakage of single sectional springs when subjected to sudden strains, and provides for a tire a wearing shoe constructed from a series of assembled short removable sections

Designs.

DESIGN FOR CARPET OR RUG.—J. S. BROWN, care of G. S. Squire, Hartford Carpet Corp., 41 Union Square, New York, N. Y. This design for a carpet or rug is oblong in form and exquisitely ornamental in composition. Inside and near the edge there is an elaborate border of figures in a white ground and a mass of small dotted circles separates this border from a bright centerpiece in a white field. Mr. Brown has patterned another carpet or rug design of the same shape with a rather dark and brilliant mixed border, separated from the centerpiece by a scrolled work runner in a white field. The centerpiece is elaborate and abounding in arrangements of flowers.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

Retrospect of the Year 1911

(Concluded from page 601.)

plane On January 30th, McCurdy attempted to fly from Key West to Havana. After covering ninety miles out of the one hundred in two hours, he fell in the sea, owing to a burned-out bearing on his motor Mr Glenn Curtiss first succeeded in rising from the water, with his biplane equipped with floats, at San Diego, on January 26th Thus was born America's first hydro-aeroplane Curtiss constructed a number of these machines, several of which have been supplied to our navy and one to that of Russia which is very active in aviation Using one of them, Hugh Robinson flew several hundred miles down the Mississippi from Minneapolis, carrying mail, which he left at the towns on route The mail-carrying experiments made on a larger scale at the aviation meet at Nassau Boulevard, together with Robinson's demonstration convinced Postmaster-General Hitchcock that the aeroplane can be used successfully for delivering mail to inaccessible places Many exhibition flights have been made in America this year, the most daring and thrilling of all having been Lincoln Beachy's clip over Niagara Falls and flight through the gorge which he made with a headless Curtiss biplane

The chief development in aviation this year has been the change from the exhibition flight to the long-distance, cross country race or tour A half dozen big races such as the Paris-Madrid, Paris-Rome, European Circuit, Circuit of Britain etc, were flown successfully abroad and were practically all won by monoplanes which appeared to be faster and safer than the biplanes In America, however, Beachy and Ely gave some marvelous exhibitions of flying in strong winds with the latter type of machine A Maurice Farman biplane on March 7th, made the 225 mile flight from Paris to the Puydc-Dome Mountain, without a stop, and carrying two men. Eugene Renaux, the pilot thus won the Michelin $20,000 prize which had been offered exactly three years before Vedrines on a Morane monoplane, won the Paris-Madrid race and secured second place in the 1,060 mile Circuit of Britain This English event, as well as the Paris-Rome and the European circuit was won by Lieut Conneau of the French navy, while Roland Garros was second in the two latter races Both of these aviators used Blériot monoplanes The Paris-Madrid race of 900 miles was covered in four days and the Circuit of Britain required but three days' flying by Conneau and Vedrines The two other machines which finished required fifteen and fourteen days respectively M Garros on September 4th, made a new height record of 4,272 meters (13,950 feet), thus beating by 2,370 feet the record of Beachy at Chicago, and climbing some 750 feet more than 2½ miles above the earth's surface

Last summer Harry N Atwood flew from Boston to Washington with his Wright biplane, carrying a passenger most of the way Later he flew from St Louis to New York by way of Chicago, in fourteen days Enthusiasm over his success Calbraith P Rodgers and Robert G Fowler started to fly across the continent from New York and San Francisco respectively Both aviators used Wright biplanes and were accompanied by special trains carrying spare parts After three unsuccessful attempts at climbing over the Sierra Nevada Mountains, Fowler finally flew to the southern route, which was the one chosen by Rodgers Rodgers left Sheepshead Bay on September 17th His route was to Chicago, St Louis, San Antonio, and El Paso, Texas, from which State he followed the Southern Pacific Railroad He finally reached Pasadena on November 5th In flying the 25 miles from there to the Pacific Ocean, he sustained a bad fall and was laid up several weeks Finally, on December 10th, he finished the first trans-continental aeroplane flight He passed Fowler at Tucson Ariz and the latter has now progressed almost as far as New Orleans.

Orville Wright conducted some experiments with a 145-pound glider at Kitty Hawk, N. C., late in October These experiments were of great interest from the fact that Mr Wright succeeded in rising in the teeth of a 50-mile gale and remaining aloft once for 7¼ minutes, and again for 9¾ minutes. In the shorter flight, he hovered for five minutes above a given spot. Mr Wright obtained valuable information relative to the designing of a machine with flattened surfaces, capable of flying in the strongest winds.

To the death list of flyers, numbering this year 76 should be added the loss of Octave Chanute, who was known as America's "Father of Aviation," and also that other pioneer, Prof. John J. Montgomery of Santa Clara College, Cal. The latter was killed while experimenting with a new glider A large number of the fatal accidents were due to recklessness and foolhardiness in making exhibition flights, but there have also been accidents from breakages of machines The causes of the various accidents have not all been determined, but the proportion of deaths to the number of miles flown is without doubt less than in 1910 The carrying of as many as six passengers on cross-country flights of one hour, and the development of an aerial taxicab, which has flown successfully, has put heart into those who believe the aeroplane has a future as a means of public rapid transit It will also undoubtedly be used for the regular carrying of mail in the near future The severe tests for French military aeroplanes resulted in seven machines making a flight of 186 miles without a stop, when carrying two men and 660 pounds of dead weight The winner was a Nieuport monoplane, piloted by Weymann, the American aviator, who also won the International Cup race for this country with the same make of machine on July 1st last He made an average speed of 72 miles an hour in the military contest with a 70-horse-power monoplane, whereas in the international race, he made 78.1 miles with a 100-horse-power motor

The development of the dirigible balloon has resulted, in Germany in a passenger-carrying rigid airship, the "Schwaben," which has made numerous sight-seeing trips about the Fatherland, running on schedule, with a regularity which has strengthened the belief in the commercial and military future of the dirigible The "Schwaben" developed a speed of practically 43 miles an hour, with 150 horse-power when accurately tested over a measured course In France, the non-rigid dirigible has been developed to a point of gratifying efficiency, and the government is building additional Lebaudys for the use of the army. For scouting, the aeroplane is simpler and, in many ways, superior to the clumsy airship At Tripoli recently, Italian aeroplanes are reported to have dropped bombs upon the Turkish troops with disastrous effect The huge English dirigible, the "Mayfly" broke in two when being drawn out of its shed, and as a consequence opinion in Great Britain is more favorable to the aeroplane Two airships, the 'Suchard' and the "Akron," were constructed this year in Germany and America for the purpose of crossing the Atlantic. The former is to start from the island of Teneriffe, and the latter from Atlantic City Neither was completed in time to attempt a flight this year, but it is probable that next spring both will start In this great attempt Mr Vaulman, after his experience with the "America" in 1910 has constructed a new and larger airship from which he believes he has eliminated the troubles which led to his previous failure

A Dark Substance in Space

IN the vicinity of the star S Coronæ Australis Innes and Worsell have found a patch of sky 25 minutes of arc in diameter where no star can be seen with a 9-inch refracting telescope According to Innes, who discusses the subject in "Transvaal Observatory Circular No 5," the apparent absence of stars in this region is due to the occurrence of some absorbing medium, interposed between us and distant parts of the universe Stars in the neighborhood of the dark region are enveloped in nebulæ; while just on the border of it there is a star which has been observed to fluctuate in magnitude between 11.0 and 12.2, and which was invisible during the years 1896-1901. The latter fact is accounted for on the supposition that the absorbing medium was for a time in front of the star, but has since withdrawn from it.

The Most Remarkable Testing Laboratory in the World

(Concluded from page 596.)

to decide whether or not a certain lubricant had spoiled a suit of clothes. The judge washed his hands of the matter and submitted the lubricant to the Royal Laboratory for Testing Materials. With characteristic thoroughness the Laboratory experimented with stains which were produced by the lubricant. First, it determined whether the stains could be eradicated by washing or only with the aid of special solvents, or not at all. Then it determined whether the color of the cloth had suffered as the result of attempting to remove the stains. Finally, it ascertained whether the strength of the cloth fiber had been impaired by the process of cleaning It reported to the court that stains made with the lubricant on cotton, wool and linen could be easily removed, that the lubricant had no injurious effect on the dyes employed, and that the lubricant did not weaken the fiber, even after prolonged intimate contact—in a word, that the cloth was not irretrievably spoiled

Settling Patent Infringement Suits.

In patent infringement suits, as might be expected, the Laboratory does yeoman service for the court It does not construe claims, for that is a matter of law; but it determines matters of technical fact, with the result that a judge is spared the necessity of considering a mass of technical data. To a layman in science, even though he be a lawyer, must seem a hopeless jumble of cryptic phrases One such case turned upon the point whether or not a certain brand of soap was so greatly superior to another in washing qualities as to be patentably different On behalf of the court, the Laboratory made a study of the two soaps to determine their solubility in water, acids and lime solutions, and their effect on dyes and on fabrics. It showed conclusively that the one soap was no better than the other

These opinions of the Laboratory on matters of technical fact are by law made binding upon the courts A judge must accept the technical decision of the Laboratory and rule accordingly

Germany has a tariff, which, like our own, is intended to protect the home producer Disputes with the customs authorities are therefore as frequent in Germany as in the United States. The American appraiser submits imported goods for scientific examination either to chemists or physicists in the employ of the customs service, or else he employs outside experts The German customs authorities call upon the Royal Laboratory for Testing Materials for assistance. In a controversy which arose between the customs authorities and an importer of mercerized cotton, the government maintained that the fabric was dyed and therefore subject to a higher duty than if it were undyed The importer insisted that the cotton was undyed Gross Lichterfelde examined the fabric scientifically and supported him in his contention.

An American Appeals for Scientific Help.

Foreigners, too, resort occasionally to the Laboratory when the questions at issue affect German industry. I was told of an American importer of German paper who had been compelled, as he thought, to pay a higher duty in the United States than the Dingley tariff required. Because the importation was an oily German paper substitute for parchment, he asked the Laboratory to tell him how treated papers could be scientifically distinguished from untreated papers. He received an exhaustive description of the turpentine oil test, armed with which he intended to appeal to the American customs authorities again. Another foreign firm wished to ascertain whether its steel hydrogen flasks met the requirements of the German police regulations governing the traffic in liquid and compressed gases. Flasks were sent to Gross Lichterfelde. There it was found that the wrong kind of metal had been employed, and that the police requirements had by no means been fulfilled.

Whenever any department of the German Imperial Government is confronted with a technical problem for solution it is

(Concluded on page 604.)

Classified Advertisements

Advertising in this column is 5c cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

AUTOMOBILES.

A NEW WHITE STEAMER. Model C-O, complete with top. Will sell at a very reasonable price. Address A. A. Hopkins, 281 St. Nicholas Ave., New York City.

BUSINESS OPPORTUNITIES.

FREE SAMPLE goes with the first letter. Something new Every firm wants it. Orders from $1.00 to $100. Nice pleasant business. We instruct. Spare hours. Write for free sample. Metallic Mfg. Co., 381 W. Court, Chicago.

OPEN FOR OFFERS. States and Canadian Patent Rights. Home Household Specialty and one Military approved articles of commission. Sellers wait. Full or light or shares and time. Address Box 773, Marshall, Consolidated Exchange, Charlingford, England.

BONUS $10,000 (nearly $5,000) offered to Inventors, Chemists, or Manufacturers for Best Paper containing (1) Process for improvements in (1) Extraction and Dressing of Fibre from the Wood and Bast of Trees, Plants, Grass, Cane. (2) Utilization of By-products, the condition that machine of process to be recommended by the New Zealand Paper Makers' Association, and approved by the New Zealand Government. Papers to be sent to the Secretaries Apply Dept. of Agriculture, Wellington, High Commissioner for New Zealand, London, or New Zealand Paper Makers' Assoc., Palmerston North, New Zealand.

PATENTS FOR SALE.

BROAD "BASIC" patent No. 1,011,391, Electric Heated Glove for drivers of all vehicles. Sell outright or on royalties. Demonstrations will require a comparatively small amount of capital to develop. A. L. Carton, Geneva, N. Y.

REAL ESTATE.

TEXAS INVESTMENTS—Buy fine sandy orchard garden lands near Beaumont, Texas, in the Rice district. Prices only in the acreage, where values are going up all the time and fortunes are made in rice. Buy now and have your crop. Write for land circular. Address A. C. Robertson, 31 Main Bldg., Houston, Tex.

WANTED.

WANTED—A man or woman to act as our information agent. All or spare time. No experience necessary. $20 to $50 per month. Nothing to sell. Send stamp for particulars. Ivy Association, Association Bldg., Indianapolis, Indiana.

MISCELLANEOUS.

ARTISTICALLY Handbeat, Faceted, Chemically, Frosted and Decorating Machine, Carries combinations; reverse instantaneously. Colors store everything needed everywhere. Interchangeable with any Electric Drill. Operating systems, Brush-working, time-saving, work-proving, Results satisfactory. Artistic Decorating Machine Company, Reade Street Building, New York.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY.—I can will find inquiries for certain classes of goods numbered in consecutive order. If you manufacture those goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Munn & Co., manufacturers of and dealers in patents, the inquiry may be regarded. MUNN & CO., Inc.

Inquiry No. 9954.—Wanted, the name and address of manufacturers of lead pencils and pen holders, such as are used by pencil manufacturers.

Inquiry No. 9963.—Wanted, to buy a patent roller, a ball-bearing roller preferred, that is patented on a royalty basis; it must be cheap and fast running.

Inquiry No. 9964.—Wanted addresses of parties having Pantheonde deposits, if able to ship ore.

Inquiry No. 9967.—Wanted addresses of firms making or using lead oxide crystals.

Inquiry No. 9968.—Wanted addresses of parties who have patents to offer to buy part of the world.

Inquiry No. 9969.—Wanted, to buy a machine for removing the centers of apples.

Inquiry No. 9970.—Wanted addresses of parties to whom to write for prices on cotton seed meal.

Inquiry No. 9971.—Wanted, a manufacturer to make a small wire article.

Inquiry No. 9972.—Wanted, to buy a machine that is to put up 100 pieces of wire, 2 inches long, in a box, 100 pieces to the box.

The Panama Canal

AT the close of last year, under the caption of The Greater "Scientific American," the publishers announced that the scope of the paper would be extended; that a series of mid-month numbers of greatly enlarged size, contained in a colored cover, would be issued, the contents being devoted to some special subject of national importance. We also announced that there would be a series of articles written by specialists in their several departments, and that these new features would be accompanied by a general improvement in the typography and make-up of the paper.

¶ The fifty-two issues of the past year speak for themselves; and their favorable reception by our subscribers and the general reading public encourages the publishers to continue the same policy, on even more progressive lines, throughout the year 1912.

Special Contributors

THE high quality of the Scientific American of 1911 will be evident from a study of its list of contributors, conspicuous among whom were President Taft, Secretary C. v. L. Meyer, Admiral A. T. Mahan, the chiefs of the various bureaus, and other high ranking officers of the navy; Secretary Charles Nagel, of the Bureau of Commerce and Labor; The Hon. John Barrett, Director of the Pan-American Union; Commissioner of Navigation E. T. Chamberlain, ex-Chief Forester Gifford Pinchot; Director F. H. Newell of the Reclamation Service; Judge Judson C. Clements, Chairman of the Interstate Commerce Commission; Dr. J. A. Holmes, Director of the Bureau of Mines; Professor Ira Remsen, President of Johns Hopkins University; W. J. Spillman, and other members of the staff of the Department of Agriculture; Robert Kennedy Duncan, S. A. Mitchell, H. N. Russell, H. W. Walker, Moyer S. Fleisher, E. L. Thorndike, T. C. Martin, and W. C. Brown, President of the New York Central Railway Company.

The list of contributors for 1912 will be equally distinguished. It will include the majority of the names above mentioned, together with others of high authority in the various fields that will be covered during the year. The Scientific American will continue to follow closely its avowed policy, as stated at the head of its Editorial Columns: "The purpose of this Journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement."

The Broad Scope of the Paper

THE subjects dealt with in 1912 will come under the heads of civil, mechanical and electrical engineering; naval and military; the merchant marine; the internal combustion motor; chemistry with special attention to electro-chemistry and electro-metallurgy; science as applied to the industries; science in agriculture. There will be the usual amount of space devoted to biography, astronomy, scientific abstracts from current periodicals and archaeology. Under the subject of inventions, particular attention will be given to the leading inventions and to patent practice, with a reference to notable cases, and there will be the usual run of inventors' notes. The popular "Workshop" and "Laboratory" departments will make their regular appearance.

The Panama Canal Number

THE great popularity of our recent Naval Number, which was immediately recognized as a brochure on the navy of unusual authority and information, has decided the publishers to prepare a similar number in December, 1912, on the Panama Canal. The material for this issue will be gathered by our Editor-in-Chief, Mr. J. Bernard Walker, who will spend some time at Panama for the purpose of making a personal inspection of this stupendous work, and securing the necessary plans, photographs and data. The number will contain a complete account of the history, construction, operation, military defenses, and commercial and naval value to the United States of this great national undertaking.

Science in the Industries

AN important feature of the 1912 program will be a series of articles by Mr Waldemar Kaempffert, Managing Editor of the Scientific American, in which he will sketch the scientific basis of Germany's remarkable commercial success—the object of this series being to offer for the consideration of the American business man certain well-proved methods for increasing the physical efficiency of the workman and the amount and quality of his output. Two of the articles will deal with German education—"The German Commercial High School", which turns out captains of industry, and "The German Vocational School", which turns out soldiers of industry. The series will also include the following articles on the relation of science to industry: "The Royal Laboratory for Testing Materials at Gross Lichterfelde" (published in this issue), "The Utilization of Waste Materials", "The German Technological Museum at Munich" (the remarkable technological museum in which the visitor is allowed to manipulate, through a crank or other means, an operative apparatus), "The Workingman as a Human Machine", "The State and the German Laborer", "City Government as a Science", and lastly, "The Commercial Utilization of Scientific Discoveries"—a summing up of impressions gleaned from a dozen factories, workshops and cities. These articles will be based upon the facts and impressions gathered by the author during a recent extensive tour of Germany, made for this express purpose.

JUST PUBLISHED

The Scientific American Cyclopedia of Formulas

The Most Complete and Authoritative Book of Receipts Published

Partly Based on the Twenty-Fifth Edition of
"The Scientific American Cyclopedia of Receipts, Notes and Queries"

Edited by ALBERT A. HOPKINS, Query Editor of the Scientific American

THIS is practically a *new book* and has called for the work of a corps of specialists for more than two years. Over 15,000 of the most useful formulas and processes, carefully selected from a collection of nearly 150,000, are contained in this most valuable volume, nearly every branch of the useful arts being represented. Never before has such a large collection of really valuable formulas, useful to everyone, been offered to the public. The formulas are classified and arranged into chapters containing related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired.

"As Indispensable as a Dictionary and More Useful"

Following is a List of the Chapters: I Accidents and Emergencies. II Agriculture III Alloys and Amalgams. IV Art and Artists' Materials V. Beverages; Non-Alcoholic and Alcoholic VI. Cleansing, Bleaching, Renovating and Protecting VII Cements, Glues, Pastes and Mucilages. VIII Coloring of Metals, Bronzing, etc. IX. Dyeing. X Electrometallurgy and Coating of Metals. XI Glass XII. Heat Treatment of Metals. XIII. Household Formulas. XIV. Ice Cream and Confectionery. XV. Insecticides, Extermination of Vermin. XVI. Lapidary Art, Bone, Ivory, etc. XVII. Leather XVIII Lubricants XIX. Paints, Varnishes, etc XX Photography. XXI Preserving, Canning, Pickling, etc XXII Rubber, Gutta-Percha and Celluloid XXIII Soaps and Candles XXIV Soldering XXV Toilet Preparations, including Perfumery XXVI Waterproofing and Fireproofing XXVII Writing Material. Send for detailed illustrated prospectus.

Lifelong Dividends for a Few Dollars Now

Marden's Books of Inspiration

John Wanamaker has just written Dr. Marden:

"Had I seen such a book as 'Pushing to the Front' when I first started towards mercantile life, I should—if it had been necessary—gone at least without one meal a day to save enough money to have bought the book."
(Signed) JOHN WANAMAKER.

12 VOLUMES **3668 PAGES**

THESE power-giving books by Orison Swett Marden show how "big" men do things; how they dig out a foothold in the business world; how they establish their credit, make opportunities, increase their abilities, double their means, widen their influence and achieve their aim — in fact, how, in spite of every obstacle, they *succeed in life.*

The most successful business men, statesmen, professional men, educators and executives have these volumes as part of their permanent libraries. Many have purchased hundreds of volumes for presentation to their employees and friends.

These books have been read and recommended by such men as Andrew Carnegie, Theodore Roosevelt, John Burroughs and Judge Ben Lindsey.

Ministers, teachers, educators, orators, writers, professional men find them invaluable as ready reference books, teeming as they are with life stories of the world's great successes.

Nearly a million copies are now read all over the world, translated into Swedish, French, German, Russian, Italian, Bohemian, Norwegian and Japanese.

Those who read them are spurred to their highest endeavor, urged forward to bring out the very best and shown how to make of themselves the most possible.

You Have a Choice

of these attractive bindings: leather silk or cloth. The leather volumes have flexible covers measure 4x6¼ inches, popular pocket size and are handsomely bound in dark maroon leather with gilt tops and silk book-mark. The silk volumes are the same size, richly bound in green watered silk in the same style. The cloth volumes are 5x7½ inches attractively bound in dark red cloth. Each set is embossed in gold, illustrated with portraits and printed in large, clear type.

This is All You Need to Do

To bring you the complete Marden Inspirational Library, in 12 handsome volumes, 420 silk-full chapters 3668 pages, transportation fully prepaid, send only the coupon and three dollars. The small amount, for 3, 4 or 5 months, as you select cloth, silk or leather binding, pays for this library complete and brings you in addition SUCCESS MAGAZINE every month for two full years (24 numbers). Every issue of SUCCESS contains one or more stimulating editorials from Dr. Marden's pen — in addition to clean and interesting fiction and outspoken articles on every big American problem. This is your chance to make your living more profitable and your life more worth while.

Send This Coupon With $3.00 Now

With Dr. Marden's latest book, "Self Investment," the Marden Inspirational Library is complete. Each one of the twelve volumes is complete in itself

The book titles are. Self Investment; The Optimistic Life; The Young Man Entering Business; Secret of Achievement; Getting On; Pushing to the Front; Be Good to Yourself, He Can Who Thinks He Can, Peace, Power and Plenty; The Miracle of Right Thought; Rising on the World; Every Man a King.

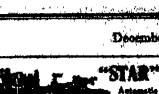
SUCCESS MAGAZINE, Dept. Y 29-31 E. 22d St., New York

almost sure to ask Gross Lichterfelde for advice. Thus, for the Royal Powder Works at Spandau, specifications were formulated for the manufacture of machine and cylinder oil, machine greases, linseed oil, turpentine oil and vegetable oils. For the Minister of Public Works a scientific test for distinguishing natural from artificial asphalt was worked out, and a study made of the thermal conductivity of refractory building materials. When the Imperial Printing Office decided to improve the quality of German post cards, Gross Lichterfelde made a study of existing cardboards and papers and practically invented a new composition which would answer modern commercial requirements. Hand in hand with the Artillery Testing Commission, tests were made with copper cylinders for measuring gas pressures. Even the German colonies consult the Laboratory, for the German governor in Togo and Kamerun submitted African woods for comparison with North and South American woods, with the result that in the near future Germany will probably draw upon her African supplies.

The institution at Gross Lichterfelde has a history that extends back to the experiments made by Dr. A. Woehler, an engineer who, in 1865, constructed the first really scientific testing apparatus employed in Germany. But the remarkable place which the institution has won in German industrial life and its world-wide reputation is due almost entirely to its present head, Geheimer Oberregierungsrat, Prof. A. Martens. When he was appointed to fill the director's chair in 1884 the entire scientific staff of the mechanical-technical department consisted of only three men, and the apparatus of two testing machines. What the development of the Laboratory has been since then may be judged from the highly varied character of the work here outlined. That astonishing development would hardly have been possible had not Maartens himself devised a very large part of the experimental apparatus which constitutes the equipment of the Koenigliches Material-Pruefungsamt.

Methods of Dust Extraction on Cotton-carding Engines

(Concluded from page 595.)



air trunk, this aperture is closed when stripping is not in operation at that machine. The draught is thus concentrated on one machine only. The aperture is automatically opened by the receiver itself as it reaches the machine to be stripped. The appliance is propelled by hand to any part desired by the workman. On arriving at a given machine, the funnel-receiver is brought immediately over the card-cylinder, close by the line where the dust is generated by the stripping-brush, and the indraught collects the dust before it can diffuse.

By a third method (Fig. 5) of dust extraction a vertical tube is provided over each carding-engine, this tube being connected with a casing or "hood," which is lowered to cover the stripping-brush when operating. A sliding shutter is fitted in the vertical tube. This is opened when ready for stripping, all other shutters being then closed. Thus the exhaust from the fan is concentrated on one "card" only. When stripping is completed the hood is raised in the vertical tube.

A fourth method (Fig. 6) has pipes depending from horizontal trunks following the lines of cards, but in each pipe is a patent valve, formed where the pipe can be flexed. When the pipe is vertical the interior is fully open; when flexed as far as possible, the aperture is closed. Hence in all tubes bent, so as to be out of the way of the workers, the valves are automatically closed. To operate this dust-extractor an aluminium cover is provided for each stripping-brush. The outlet pipe of the cover fits into the down-pipe just mentioned, so that when the fan is started the dust is drawn off as stripping proceeds. The power required for an average mill is estimated at about one horse-power.

The method now described (Fig 7) works on a portable principle. The stripping-brush is inclosed in a hood which has a flexible-tube connection with the dust-extractor. This comprises a portable chamber built on an angle-iron frame, braced with tie-rods and bolts, and having a wooden top and base. The

CATALOGUE containing a complete LIST OF THE
Manufacturers of ELECTRIC MOTORS
Westchester, Conn

whole is moved on wheels after the style of a bogie, and contains the exhaust fan and dust-bag. When stripping, the fan is operated by bands running from the carding-machine to grooved pulleys on the ends of the fan-shaft, these pulleys availing for right- or left-hand cards. The stripping of a card having been completed, the brush and casing are placed in brackets on the top of the chamber, and the next card is similarly treated.

Most of these dust-extractors perform another important function. They may be used as ventilators of rooms generally, apart from the removal of dust from carding-engines. The stripping process is performed four times each day, and occupies 40 to 60 minutes. In the intervals between these operations any of the apertures of the dust-extractors may be opened in any part of the room. Impure air may thus be drawn from twenty or more localities at the same moment by moderate exhaust currents, and without draughts playing on the workers. The improved condition of the air from the use of these widely-distributed exits will be readily appreciated.

With the installation of dust-extractors in the card-rooms of cotton mills, the health and working efficiency of the operatives concerned will be considerably improved. Likewise the material produced, in the shape of finished yarn, being free from specks of dust, will be very materially enhanced in its market value.

Telephones in Great Britain

ON December 31st, 1911, the telephone service of the United Kingdom will become, like the telegraph service of that country, a government monopoly.

The history of British telephones is reviewed in a recent report of Consul Rufus Fleming, stationed at Edinburgh. An act of 1869 gave to the Postmaster General the monopoly of operating telegraphs, and in 1890, as a result of the case of the Attorney General vs. the Edison Telephone Company, it was decided that telephones were included in the provisions of this act. However, the government, instead of buying up the patents and taking the telephone service into its own hands, granted licenses to the existing telephone companies. At first the companies were restricted in their operations to limited areas, but from 1884 onward the licenses were applicable over the entire kingdom. This led to the organization of large companies, and by 1892 practically all the business was in the hands of the National Telephone Company, Ltd. In 1896 the government took over the operation of all the trunk lines connecting one town with another, paying the company upwards of $2,333,725. The latter has since continued to operate the local lines, but will transfer all its business to the postoffice at the end of the present year.

There are approximately 644,000 telephones in the United Kingdom, but it is estimated that if the system were used in the same ratio to population as in the United States, the number would be nearly 3,000,000. Judging from the history of the telegraph service, it is expected that the transfer of the telephones to the government will result in a great extension of the system.

A Fiber Exposition in Java

A UNIQUE exhibit of fiber plants and fiber-working machinery has been held at Soerabaya, Java, during the past summer, in connection with the Fiber Congress of the East Indies, which opened July 3rd. Dutch, German, and British machinery was represented, made by Krupp, Benisch, Berand Liebescher, Lees & Co., and Oldham. All the fiber plants of Java, and many from the Philippines, Siam, etc., including sisal, agil, pineapple fiber, banana fiber, coconut fiber, Java cotton, kapok, and others, were exhibited. One exhibit showed the natives of Java working kapok and cotton from the very first stage of preparing the fiber to the finishing of the woven cloth.

Kapok is the silky fiber surrounding the seeds of the silk-cotton tree (*Ceiba pentandra*), one of the noblest trees of the tropics. It is extensively used in stuffing mattresses, and also in filling life-preservers, for which latter use it is especially valuable, as it will support a greater weight in water than any other substance used for this purpose. A mass of pressed kapok will support thirty-six or thirty-seven times its weight.

How'd You Like to Be the
AIR-[illegible]-MAN

CURRENT LITERATURE

Sweeps the whole field of the activities and thought of the day—American Politics; International Affairs; The Men of the Hour; Progress in Science and Invention; The Religious and Ethical Problems of the Day; The News of the Artistic and Literary World; The Best Plays of the Season; The Great Questions of Finance and Industry; The World's Achievements in every field. Universal in outlook, impartial in presentation, it mirrors the world's news month by month. Edwin Markham says that Current Literature is a "sort of peep-hole into the whole drama of human affairs." Profusely illustrated with Cartoons and Photographs. The most complete, the best balanced, the most informative magazine published. No matter how many magazines you may take, you need Current Literature. If you take only one magazine, Current Literature should be that one.

$3.00 a year—25 cents a copy.

Many of the leading clubbing offers may be obtained in combination at reduced prices. For example

Current Literature Cosmopolitan Good Housekeeping	All three for **$3.75** Reg Pr $6 00	Current Literature American Woman's Home Comp'n	All three for **$4.05** Reg Pr $6.00
Current Literature Everybody's Delineator	All three for **$3.95** Reg Pr $6 00	Current Literature McClure's Scientific American (new)	All three for **$5.40** Reg Pr $7.50

A handsome catalog giving the prices of all the leading periodicals and showing how you can get any combination of magazines you wish at the lowest possible rates will be sent on request.

CURRENT LITERATURE MAGAZINE, 140 WEST 29th STREET, New York City.

"I knew that Sanatogen would build you up"

THE physician who advises Sanatogen acts with confidence, and watches with confidence for results, because he is dealing with *known elements* of reconstructive power—because he has *seen these elements do their splendid upbuilding work.*

The physician who advises Sanatogen also has behind him the written endorsement of *15,000 other practicing physicians* who testify to the vital force, the nourishing, *renewing* action of this remarkable food tonic.

Sanatogen is science's logical answer to the call of the nerves, the *food* answer to the hunger cry of impoverished conditions, however these conditions may have been brought about, by fret, illness, stress of work, domestic, business or social vicissitudes—with distressing results in sleep, in appetite, in "blues," in outlook on life.

Sanatogen meets the *needs* behind this debilitation. It *feeds*, upbuilds, revitalizes nerves and tissues—encouraging brain and body to develop new power.

You may wisely feel the confidence bestowed by so many thousand men of science, and echoed enthusiastically by so many other thousands of the world's famous men and women.

WRITE FOR A FREE COPY OF "OUR NERVES OF TOMORROW"

The work of a physician-author, beautifully illustrated, which tells you some really interesting things about your nervous system, facts which vitally affect your well-being and which therefore you ought to know. This book also tells the story of Sanatogen convincingly from the point of view of a physician, but as that fact by-passes one unthinned by

Sanatogen is sold in three sizes: $1.00, $1.90, $3.60

Get Sanatogen from your druggist—if not obtainable from him send direct, stating of what he

THE BAUER CHEMICAL COMPANY, [illegible] Re.

The world makes way for the man who knows

In this age of efficiency you can't ***guess,*** or ***suppose*** or ***think*** a thing is right—you must ***know.*** The man who does know is the man who is marked for success—he is the man the good job seeks—he is the man who gets the money—he is paid for what he knows—not for what he does.

The American School of Correspondence publishes sixteen Cyclopedias, comprising ninety-eight complete volumes, covering completely the fields of ***Engineering, Business*** and ***Law.*** This great library is especially adapted for the use of the busy business man—the expert or professional man—the student or clerk, because it contains in condensed and quickly accessible form just the information he wants, when he wants it.

What these Cyclopedias are: These great Cyclopedias are not collections of theories, but complete reviews of the actual, tried and tested experiences of the greatest engineers, business men, and law experts in the world. The books are not dictionaries of disjointed facts—not dry technical works, but clear and simple explanations of every phase and every branch of ***Engineering, Business*** and ***Law.*** They are books that every man needs in his library—books that will increase your salary by increasing your knowledge.

Reference value guaranteed by the fact that the books are compiled from the text books used in the correspondence courses of the American School of Correspondence. These practical lessons are arranged for quick reference, and the new cross index enables you to turn to any subject in an instant.

We prove their value to you by sending the set you select on approval. If the books are not all we claim them to be—and—more—do you think we could afford to take this chance?

No chance for you to lose—no deposit required—no transportation to advance—nothing to pay unless the books are just what you want.

ANOTHER GREAT FREE OFFER

With each set is included a Consulting Membership entitling you to the advice of our Engineering, Business and Law experts absolutely free of charge. This will give you practical help in handling problems which are too specific to be taken up in detail in the Cyclopedia. There will be no limit to the service. A single problem solved for you might be worth more than the first cost of the books. Order the books you need now. Don't wait until you actually need them, then it's too late. These books answer every question in Engineering, Business and Law quickly and accurately.

Remember—it costs you nothing to examine the books—you will save money by owning them. Mail the coupon—make your final decision with the books before you

COMPLETE LIBRARY OF ENGINEERING, BUSINESS AND LAW

CYCLOPEDIA OF

Civil Engineering	8 vols	$24.00	Automobile Engineering	4 vols.	$12.00
